To an older generation, reared in the prudish atmosphere of the late Victorian era, the literature of today is inexpressibly vulgar and immodest. It was taught to say limb instead of leg and believed that *Robert Elsmere* was a wicked, vicious book; many a careful mother would not allow *Trilby* in the house because some doubt was cast upon the heroine's purity; the dime novel and kindred scribblings were under the parental ban.

It is difficult to imagine a modern child as even desiring to read such pallid publications. *Robert Elsmere* is inexpressibly boring to the reading public of today. Nobody cares whether or not he was wicked. As a matter of fact, compared with the heroes who strut through the books of the hour, his was a saintly character. Poor *Trilby* was a colorless nun beside the long procession of prostitutes which marches through our "six best sellers." *Nick Carter* and all the other notables of the Jesse James school of fiction haven't a thrill for the child who nightly sees fair ladies thrown over the cliff by burglars who have just given a practical demonstration in the art of safeblowing.

Illegitimacy used to be a word to be spoken beneath the breath; nowadays no novel is complete unless it has at least one child born out of wedlock. Adultery was once a word which made people self-conscious when they recited the Ten Commandments; recently a cleareyed British judge asserted in the course of a world famous trial that "adultery is to the young people of the present day merely a quaint ecclesiastical term for what seems to them the great romantic adventure of their lives."

What is the effect of this flood of pornographic thought upon the public mind? It used to be the rule in the more risque novels of three decades ago that the girl who left the path of virtue inevitably became a mother. What is the consequence of an avalanche of books which show that the socalled wise girl need suffer no penalties for indiscretion provided the fact is not too widely known? What is the child's reaction to a movie which depicts the principal character as following the path of dope and degradation only to be miraculously salvaged by a beautiful heroine or sturdy hero, immediately rehabilitated in the community and settled in a life of luxurious prosperity and respectability? The boy who sees night after night just how crimes against society may be committed is gaining dangerous knowledge; disrespect of law and order is engendered by witnessing the filmed spectacle of the making of homebrew and such turning of disobedience of the statutes into a joke.

One of the shibboleths of the health movement is "the health education of the general public." Thinking health workers believe that the focal point of this education is the child. The attempt is made to indoctrinate obedience of the laws of personal and civic health, to teach the citizens of tomorrow to live lives of mental and physical cleanliness, purity and decency, to bring them to the acceptance of community responsibility. This is laying the cornerstone of the health edifice of the nation. Capable, selfless men and women have dedicated their lives to this cause, yet day by day the commercialized thrill mongering of press and camera is tearing down that which has been so carefully wrought. As at present conducted, the censorship of motion pictures is a deceitful farce; of the censorship of the decadent literature of per-

version which the public is now greedily consuming, there is none.

The assertion is made that this fashion of vulgarity and florid passion is a symptom of the expansion of individual liberty, that out of this iconoclastic destruction of the code of decent selfrestraint will grow a larger freedom, that this wholesale exhibition of the nastiness of depraved minds will arm the child for life's battle, that the older generation has always acted as a brake on the wheel of progress by its rigid adherence to the standards of the past. These arguments are fallacious. Pruriency is not liberty; freedom does not grow upon filth; defilement with the muck of salacity is not an armor but a weakness; standards of human conduct which have stood the acid test of time are more reliable than the unproven theories of license.

The great hope lies in the stimulation of fastidious refinement in the public school child. The desire to excel in sports, the love of clean air, clean food and clean bodies carry with them an unconscious love of clean minds.

SYPHILIS OF THE THYROID GLAND

Physiological and clinical research of recent years has proved beyond a doubt that exophthalmic goitre is due to a lesion of the thyroid gland. A thyroiditis, which usually evolutes unnoticed, is the onset of the syndrome. Histologically, this thyroiditis provokes a glandular dyshyperplasia, a lesion which progressively develops and little by little vitiates the endocrine secretion. Numerous infectious processes give rise to Basedow's disease, especially tuberculosis, typhoid fever and acute articular rheumatism. Syphilis appears—among the etiological factors incriminated—to have been somewhat neglected by clinicians regardless of its great frequency and the well known multiplicity of its lesions.

Clinically, the action of the spirocheta pallida on the thyroid gland may produce a secondary or tertiary thyroiditis, a gummatous, sclerogummatous or interstitial form, syphilitic dysthyroidies and later manifestations, among which myxedema and exophthalmic goitre are to be found.

It is very probable that Basedow's disease of syphilitic origin will be more frequently diagnosed when it has become better known to the profession than it is at present. However, cases occurring during the evolution of acquired syphilis are becoming more numerous. The syndrome may appear at any time during the morbid evolution, sometimes in full secondary stage, at others in the tertiary phase, and occasionally as much as a quarter of a century after the chancre. The localization of the initial lesion, the virulence of the infection, the intensity and continuity of the specific treatment do not appear to play any part in the ulterior appearance of the disease.

Exophthalmic goitre may be also encountered in hereditary syphilis where it is more prone to assume a larvate form when the luetic virus is very attenuated. The notion of infection would likewise seem to explain the histories of familial Basedow's disease, which until now have been regarded as the result of neuropathic heredity, which at present must be looked upon as very problematical.

The morbid associations that exophthalmic goitre contracts with various diseases would seem to plead still more in favor of the frequency of its syphilitic origin. In reality, the clinical entities associated with Basedow's syndrome are invariably, or at least frequently, tainted by syphilis, as in order of frequency one has locomotor ataxia, general paralysis, epilepsy, chorea, vitiligo, and so on.

Syphilis thus deserves an important place in the etiology of exophthalmic goitre and when making a diagnosis of this affection the patient's antecedents, morbid associations, Wassermann reaction and results of specific treatment should be examined.

It is probable that as time goes on and still greater advances are made in laboratory technic that larvate forms of syphilitic exophthalmic goitre will be detected and by an early diagnosis specific treatment can be carried out almost from the onset of the process, namely an intensive and long continued resort to the arsenical compounds and mercury preparations, while in stubborn cases iodine medication is indicated.

ASTHENIA DEPENDENT UPON POLYGLANDULAR DISTURBANCES OF SYPHILITIC ORIGIN

During the past twenty years syphilis has singularly widened its domain, hence of late certain types of asthenia due to polyglandular disturbances of syphilitic origin have been reported, whose pathogenesis has been surrounded by obscurity. These disturbances are principally met with in women without any clinically appreciable factor. The patient complains of a continual or intermittent state of fatigue, which is increased by the most varied causes. They suffer and their household likewise and no means can seem to be found to procure permanent recovery. This morbid state, most variable in degree, is subject to alternatives of amelioration and relapse. Usually these subjects are regarded as poor in health or apathetic, incapable of any continued work. By rest, quiet, isolation, life in the open, or opotherapy and physiotherapy, a sedation of the symptoms may result, but it is temporary and incomplete. From the merest shock the morbid state returns and these relapses react on the mental state

nd change the patient's psychism. They become motive, depressed and physically unfit.

The pathogenic formula of these phenomena vary with the current medical doctrines—autointoxication from slowed metabolism; intestinal disturbances and chronic enterocolitis source of intoxication; general nervous disequilibrium; constitutional neurasthenic state, etc. The recent studies of functional disturbances and isolated or synergic changes of the endocrine glands seem to have thrown new light on this question of cryptogenetic asthenia. The well known asthenia of Addison's disease has put observers on the right road, and on the other hand, the part played by syphilis, especially the hereditary form, in the pathogenesis of certain pluriglandular syndromes no longer seems to be doubtful. Certain groups of facts are of a nature to carry conviction. The recent work of Hutinel, Lereboullet and Mouzon place the syphilitic antecedents in the rank of the constitutive element of this morbid process, while Hutinel has demonstrated the preponderant intervention of hereditary lues in glandular dystrophies of early life, particularly in their mild, discrete forms which are the most common. Hence syphilis realizes an attenuated type of the pluriglandular syndrome.

In the asthenic subjects in question, signs of endocrine disequilibrium are met with, such as headache, vertigo, indefinite pain, arthralgia, mild edema and above all a high blood pressure. The list of symptoms is most incomplete, their variety and polymorphism prohibiting the conclusion that a single gland is involved, but rather multiple involvement of the endocrine system. The asthenia rarely is the only phenomenon present, orthostatic albuminuria, frequently associated with vertigo and dyspeptic disturbances, often coinciding with it. Hence Merklen and his school believe that many cases of asthenia should be regarded as a polyglandular disturbance having a luetic basis.

This conception is in conformity with what we know of the asthenizing character of syphilis undergoing its evolution. Fournier referred to the asthenia of the secondary phase and it has been generally noted in the serious accidents of this infection, such as cerebral syphilis and tabes, while Hutinel has referred to laziness, indifference, want of intelligence, memory and attention in hereditary syphilitics.

In the cases envisaged the proof of their syphilitic origin is not at once apparent, because objective evidence is wanting. These are patients with ignored syphilis or who have given up specific treatment long since, or else they are hereditary syphilitics without symptoms. Occasionally the asthenia develops after labor, an acute disease of the crisis of puberty, all of which conceal the true origin of the asthenia. Nevertheless, there are three proofs of the specific nature of the asthenic accidents. First, syphilis is often found in the husband or wife of the patient, be it admitted or detected by clinical and serological examination. Secondly, when the patient is a sickly, debilitated child, with mediocre intelligence and lazy, syphilis should be looked for in the parents and hereditary lues will often be discovered in the child. Lastly, in instances of syphilitic asthenia the Bordet-Wassermann is positive. Should doubt exist the more sensitive antigen of Desmaulière should be employed as it reveals the presence of mildly virulent syphilis.

The results of specific treatment are to be taken into account and will usually have a marked beneficial action where all other modern treatments have failed, recovery actually ensuing.

THE CEREBROSPINAL FLUID IN HEREDITARY SYPHILIS

In an unusually complete study on this subject (*Thesis,* Toulouse, 1924), Dr. Bounhoure shows that hereditary syphilis is far less frequently mucocutaneous in its manifestations in children, while it gives rise to specific lesions in the neuraxis and its envelopes, as well as in the visceral parenchymas. What most usually are observed are those lesions involving the nervous system and it is these processes that are chiefly studied by Bounhoure.

In all cases where nervous syphilis is suspected lumbar puncture is imperative for the study of the cerebrospinal fluid. The percentage of albumin must first of all be ascertained which, in the normal state, is ten cgm. to the thousand c. c. Hyperalbuminosis is mild in the chronic hereditary syphilitic encephalopathics; it becomes more marked— thirty to forty cgm. and more—in hydrocephaly and in the convulsive syndromes and in acute luetic meningitis.

Cellular reactions—lymphocytosis—are strong, medium or *nil* according to whether the process is acute or chronic, as well as the importance of the lesions. If the Bordet-Wassermann is done, it will be found positive in the serum in thirty-seven per cent. of children presenting a certain or probable hereditary syphilis, while in the cerebrospinal fluid the proportion of positive results attains fifty-two per cent. A positive reaction in the blood serum is a valuable sign in favor of hereditary syphilis, while in the cerebrospinal fluid it is practically a sure index of hereditary lues, especially when other changes of this fluid exist at the same time. Nevertheless, it is to be noted that during meningeal reactions in children a positive Bordet-Wassermann may ensue, but this becomes negative after the natural recovery from the acute episode without specific treatment, while during the evolution of a tuberculous meningitis in

a hereditary syphilitic the reaction may become positive from a kind of activation. In the purulent meningitides the reaction may be positive.

As to colloidal benzoin reaction, Bounhoure regards it as a very precise means of investigation, sometimes more sensitive than the Bordet-Wassermann, but as far as hereditary syphilis of the neuraxis is concerned, negative results of Guillain's reaction appear to be rather frequent. Undoubtedly this can be explained from the relative rarity of evolving syphilitic neuraxitis in young hereditary syphilitics. In many cases one is dealing with cicatricial sequelæ or dystrophies, these being fixed lesions generally giving rise to a negative benzoin reaction. In evoluting acute cases the Bordet-Wassermann and benzoin tests are both positive.

Lange's colloidal gold reaction was found to be more sensitive than the Bordet-Wassermann, and in the majority of cases the results were parallel with those of benzoin. But this reaction does not always appear to be specific and it must be admitted that its technic is delicate.

A FRENCH SARANAC

Next to Austria, France has the largest mortality rate from tuberculosis of any country in Europe. Realizing this fact, some prominent citizens of the country and Americans living in Paris started about two years ago a movement to supply France with a sanitarium for tuberculous persons that should be of the latest and most approved type, and equipped with all the requirements necessary to affording the best methods of care and treatment. With these ends in view, a village is now in process of construction which is patterned after our Saranac in the Adirondacks. Small houses are being built after Swiss chalet models on a plateau four thousand feet high near the little town of Passy, within sight of Mont Blanc, and just across the valley from St. Gervais-les-Bains. Each cottage will take care of from four to six patients. The initial bed capacity will be about four hundred, but additional houses will be built as fast as funds are forthcoming. The village will have a central laboratory and administration building, and a sanitarium for patients who are unable to pay for their care.

The French Government, because of its war burdens, has so far been unable to render material aid in this work, but it has given its formal recognition and support of the plan. The necessary funds are being raised through private subscription, a sum of more than one million francs having already been donated.

A committee has been formed to finance a memorial to the late Dr. Trudeau, who was a native of France but who came in search of lost health to America, where he remained and founded the great sanitarium at Saranac on Lake Placid. Members of this committee are Livingston Farrand, James A. Miller, William B. James, president of the Trudeau Sanitarium, and Edward R. Baldwin, of the Trudeau Foundation. American subscriptions are being received by Dr. Lucien Jouvard, president of the French Hospital of New York City, and treasurer of the committee.

OUR LATIN AMERICAN NEWS

People who live in the United States are likely to think of Central and South America as a vast wilderness, with a low degree of civilization and a generally backward cultural state. This impression is not correct. It is true that most of the countries south of the Rio Grande are not thickly populated, and in most of them the aboriginal Indian stock predominates, but a new spirit has come over Hispano-America, and with the improvement in the economic situation there is a broadening horizon for medicine and public health. The standards of living are being raised, and in Santiago, Chile, and the other capitals there is a degree of culture which will compare most favorably with that of cities of similar size in North America. As a result, there is an augmentation of social and community welfare work, and an improvement in the hospitals and similar institutions. Public health has taken hold of the upper classes, and the peasant finds himself being gradually led into the more hygienic ways of living. The schools now enjoy a greater latitude in their curricula, and health preservation is being inculcated to a greater extent in the rising generation. An endeavor is being made to combat illiteracy, and public sanitary works are being installed in cities which were old before Jamestown was settled. It is therefore thought that the readers of the Medical Journal and Record may find interest in some news items demonstrating the way in which progress is being made in Latin-America.

Obituary.

HUGH WALSHAM, M.D., F.R.C.P.

Dr. Hugh Walsham, M.D., F.R.C.P., who died at his residence in Harley Street, London, on April 13th last, was best known for his pioneer work, begun as early as 1896, on the application of the x rays to the diagnosis of intrathoracic disease. He was consulting physician to the City Chest Hospital, and consulting radiologist to both St. Bartholomew's Hospital and King Edward VII Sanatorium, Midhurst. Born in 1853, he was sent to King's College School, and went up to Cain's College, Cambridge, being also a student at St. Bartholomew's Hospital and at the Great Ormond Street Hospital for Children. In 1903 he was awarded by the Royal College of Physicians the Weber Parkes Prize and first medal for research work on tuberculosis. At the meeting of the British Medical Association in Birmingham in 1911 he was president of the Radiology

ection, and was vice-president of the Radiology ection of the International Congress of Medicine n 1913. Dr. Walsham published *Stereoscopic Skiagaphy in Diseases of the Chest,* 1899, and with Harison Orton *The X Rays in the Diagnosis of Diseases f the Chest,* 1906, as well as numerous papers in he professional journals. His chief recreation was he study of astronomy, especially solar physics. Dr. Walsham did not escape the penalty paid by most f the early x ray workers who failed to realize the isks they ran. But as a friend wrote of him: "With eady selfforgetfulness he discounted the loss of is hands in the largeness of his heart and of his esire to help and heal. It was a very patient and eroic ending to a noble and heroic life."

News Items.

Hospital News.—Plans are being made for a $600,000 ospital at Stamford, Conn.,

A bond issue was recently made for a $600,000 hospital t Tampa, Fla.

It has been proposed to erect a maternity and a children's ard at St. Joseph's Hospital, Far Rockaway, as a memorial to the late Dr. William L. Mulcahy. The estimated ost of the project is $200,000.

Industrial Hygene Clinic.—The Industrial Hygiene Division maintains jointly with the Reconstruction Hospital nd the College of Physicians and Surgeons a clinic for the tudy, diagnosis, and treatment of the industrial diseases. This clinic is situated at the Reconstruction Hospital, corner f 100th Street and Central Park West. Not only will ccupational diseases be studied, but later when the clinic rows doctors and nurses will be given special training in he methods of industrial medicine and surgery.

Society News.—Dr. Donald A. Nicholson, of Seattle, as elected president of the Washington State Medical Association, at the annual meeting held at Everett on August 14th, and other officers were elected as follows: Dr. Frederick H. Brush, of Yakima, first vice-president; Dr. Andrew A. Matthews, of Spokane, second vice-president; Dr. Curtis H. Thomson, of Seattle, secretary-treasurer, and Dr. John H. O'Shea, of Spokane, assistant secretary-treasurer.

A congress on military medicine and pharmacy will be eld in Paris, April 25, 1925. The two previous meetings were held in Brussels and Rome.

The National Safety Council will meet in Louisville, Kentucky, September 29th to October 3d. Many papers of interest to industrial physicians will be read.

The Colorado State Medical Society will hold its next annual meeting in Denver October 7th, 8th, and 9th, under he presidency of Dr. Melville Black, of Denver.

Civil Service Examinations.—Among the positions for which examinations will be held on October 4th by the Civil Service Commission of the State of New York, are the following:

Assistant Physician or Intern, County Tuberculosis Sanatoriums. One immediate appointment expected at the Broome County Tuberculosis Hospital at $1,500, one at the Glenridge Sanatorium in Schenectady County at $2,000 and one at Suffolk Sanatorium at Holtsville, N. Y., at $1,500.

Medical Inspector of Factories, State Department of Labor. $3,000 to $3,500. Age limits twenty-five to fifty years. Immediate appointment expected.

Psychiatrist and First Assistant, State Institute for Defective Delinquents, Napanoch, N. Y. One immediate appointment expected at $2,800 plus $720 to $960 a year allowed in lieu of maintenance.

Pathologist, State Institute for the Study of Malignant Disease, Buffalo. One immediate appointment expected at $5,000. Age limits thirty-five to fifty years.

Assistant Physician and Assistant Surgeon, State Hospital and Institutions. Salaries vary.

Technical Assistant (Immunology), Division of Laboratories and Research, State Department of Health. $1,201 to $1,500. Immediate appointment at $1,260.

Upper Egypt Health Resorts.—Announcement is made that the health resorts of Upper Egypt—Assouan and Luxor—have now returned to their prewar efficiency. This is of general importance, as they are well organized, and the English physicians practising during the winter season (November to March) have had great experience of the special advantages of the Upper Egypt climate in the treatment of such illnesses as rheumatoid arthritis, kidney disease and albuminuria, chronic bronchitis, asthma and other conditions. It is well known that Assouan as a health resort has the driest climate in the world, and the results obtained are remarkable. Dr. Leigh Canney, who has practised for over twenty years in Upper Egypt, is not returning, but will be succeeded by his colleague Dr. Percy Moore, who will be residing at Assouan during the season (November to March) in future.

Dr. Uhls Reports on Eye Conditions in the Near East.—Dr. Russell T. Uhls, of Kansas City, Missouri, recently returned to this country from four years' service with Near East Relief in the Russian Caucasus. Dr. Uhls has probably had a wider experience in the treatment of trachoma than any other oculist in the world. At the huge Near East Relief orphanage at Alexandropol he and his assistants gave approximately 112,000 treatments a month to an army of ambulatory patients. In three years he reduced the number of sufferers from this scourge in the Alexandropol hospitals from fourteen thousand to three thousand. Dr. Uhls travelled more than ten thousand miles into Turkestan, Persia and Central Asia studying the eye conditions which are so serious a menace to not only the Orient but the entire world. The reports which he brings of his experiences will be welcomed by ophthalmologists and by students of the medical aspects of immigration.

Personal.—Dr. Walter J. Craig, assistant director of Johns Hopkins Hospital, has resigned to take a position in the department of surgery at Yale University. He will be succeeded at Johns Hopkins by Dr. John H. Snoke, who until recently was superintendent of St. Luke's Hospital at Shanghai, China. Dr. Craig will become assistant resident surgeon in the New Haven Hospital, where he served as intern after he was graduated from the medical school.

Dr. Archibald Mercer, of Newark, has resigned as president of the Medical Society of New Jersey, on account of poor health. Dr. Lucius F. Donahoe, of Bayonne, becomes acting president.

Dr. Lancelot Ely, of Somerville, N. J., has been promoted from Major to Lieutenant Colonel of the Medical Officers' Reserve Corps.

Mr. Carl A. Brimmer is the new superintendent of the Mansfield General Hospital, Mansfield, Ohio. Mr. Brimmer was formerly superintendent of the Touro Infirmary Hospital of New Orleans.

Dr. Francis V. Gowan, of Philadelphia, has been appointed instructor in laryngology at the University of Pennsylvania Graduate School of Medicine.

Dr. J. H. L. Cumpston, Director General of Health of Australia, paid a brief visit to the State Department of Health at its Albany headquarters, on Saturday, August 23d. He was accompanied by Dr. F. F. Russell, general director of the International Health Board and member of the New York State Public Health Council.

Dr. John A. Fordyce has been elected a foreign honorary member of the Vienna Dermatological Society.

Dr. Wells P. Eagleton, of Newark, N. J., recently sailed from San Francisco, on a trip around the world.

Dr. Charles B. Keeley, of Jersey City, has been appointed a member of the New Jersey State Board of Medical Examiners, to fill the vacancy caused by the death of Dr. John J. Mooney.

Dr. Carlisle S. Boyd has been appointed attending physician to the Willard Parker Hospital.

Dr. Harry R. Wahl, professor of pathology and bacteriology at the University of Kansas, has been appointed acting dean of the Medical School.

Dr. Frederick H. Verhoeff has been appointed professor of ophthalmic research in the Harvard Medical School, and Dr. George S. Derby has been appointed Williams professor of ophthalmology to succeed Dr. Alexander Quackenbos, recently retired.

Dr. Burton T. Simpson, of Buffalo, has been appointed superintendent of the State Institute for the Study of Malignant Diseases to succeed the late Dr. Harvey R. Gaylord.

Foreign Correspondence.

VIENNA LETTER

(From our own correspondent)

Vienna, *March 20, 1924.*

THE STUDY OF UROLOGY IN VIENNA

Urology as a separate specialty had its origin in Vienna, when Nitze demonstrated the first cystoscope before the Gessellschaft der Aertzte in 1879. From that time until the present, Vienna has been recognized as a centre of urological teaching, many of the most prominent urologists in America and on the Continent having been students there under such leaders as Von Frisch, Ultzman and in later years, Zuckerkandl, the latter being the founder of the present Vienna school of urology.

Vienna today presents a great variety of opportunities to the American student of urology. The largest and best equipped of the hospitals is the Kaiser Jubiliumspital. The urological service consists of sixty beds under the direction of Primarius Kroiss. Among the other leading clinics are those of Rubritius, who has a service of twenty-five beds at the Wiener Poliklinik, Blum at the Sofienspital, and Gagstatter at the Rudolfspital also having about an equal number. There are other smaller urological departments scattered throughout the city, each one of which has attached to it as an integral part, a proportionately large outpatient department.

While urology as such is established on a firm basis, it still meets with considerable opposition from the general surgeons, especially the older men. Von Eiselsberg, who is the head of the First Surgical Clinic and a great power in medicine in Vienna, considers urology as a subdivision of general surgery, and has not organized a urological department in his clinic. Practically all the other large hospitals, however, have urological services entirely independent of the general surgical service.

American physicians going to Vienna and desirous of doing postgraduate work of any kind should go at once to the American Medical Association which is located on Spitalgasse directly across the street from the Allgemeines Krankenhaus. This organization was founded in 1901 by a group of Americans, and except for the interruption necessitated by the war, has, in spite of a constantly changing personnel, continued to function ever since. Membership is not restricted to Americans, all English speaking physicians being eligible to membership on payment of a small fee. There are usually about 125 enrolled from all parts of the world.

All work is arranged for through the association, the various courses in progress or in process of organization are posted on bulletin boards in the club rooms, with full information as to length of course, fee, instructor, etc. All fees are paid through the desk secretary, who has been with the Association since 1910, and is very well informed on all matters pertaining to medical study. She is also familiar with hotels and boarding houses, the rates they charge and the accommodation they can provide, and can even provide governesses for those doctors who may come over with their families.

Fees charged for courses are fixed by agreement between the officers of the association and a committee of the faculty of the University of Vienna. This obviates the necessity for any bargaining between individuals, and has done much to promote good feeling between members of the faculty and the association. Prices charged vary from three to six dollars an hour, depending upon the type of work and the rank of the instructor. This charge is divided *pro rata* among the men taking the course. Certain of the professors such as Tandler in anatomy or Finger in dermatology receive ten dollars an hour for their courses, but these are didactic hours, at which ten or more men are present so that the cost is not excessive. The American Medical Association publishes a yearly catalogue containing all this information—a copy of which may be obtained by writing to the secretary in Vienna.

Work in urology may be obtained in two ways—by working as externe in a hospital and dispensary, and by taking courses. A combination of the two is very desirable, especially for the man who intends to remain a longer period of time. A man wishing concentrated work on a single phase of the subject, can best obtain what he desires by taking courses in this subject, at which specially selected material is presented. It is here that the question of language comes up. Practically all courses are given in English, and ignorance of the German language is no barrier in that respect. For work in the hospital and outpatient departments, however, a knowledge of German is extremely desirable, in order to understand what is said at ward rounds, and to obtain histories from patients.

Americans are received into the clinics on quite the same basis as the native Austrians, the amount of work given to them depending upon the length of time they remain in the clinic and the ability and interest displayed. They are assigned cases, make the necessary examinations, cystoscopic and otherwise, administer treatments, and assist in the operative work. Their knowledge of German permitting, they are assigned bed patients, writing histories, etc. Courses in cystoscopy, urethroscopy and clinical urology are usually given late in the morning.

Afternoons are usually devoted to anatomy and pathology. Cadaver material is extremely abundant, an autopsy being performed on every patient dying in any public hospital. Autopsies are performed in the morning, and in the afternoon, the organs of these postmortem examinations are presented in the gross pathology course, together with the clinical findings, diagnosis, treatment, etc. All errors in the clinical management of the case are duly brought to light, sometimes much to the chagrin of the clinician.

Anatomical dissections can be made at the Anatomical Institute under the supervision of the assistants in the institute. Operative surgery on the cadaver is very readily to be had, there being an abundance of fresh material at the Pathological Institute of the *Allgemeines Krankenhaus* or at any of the larger outlying hospitals. A great deal of this work is done at the Kaiser Jubiliumspital.

There are a number of courses given in Vienna that because of their great merit, deserve special mention. Professor Tandler, who together with the late professor Zuckerkandl, has just published a book on the *Anatomy of Prostatic Hypertrophy*,

gives a course on the anatomy of the pelvis, that always attracts more than a full quota of men. He has some splendid specimens of the various types of prostatic hypertrophy. Professor Stoerk, who specializes in the pathology of the genitourinary organs, and has done a great deal of work on Grawitz tumors, presents a course in genitourinary pathology, both gross and microscopic specimens being shown. The clinical history of the case is given and discussed from the viewpoint of possible errors in diagnosis and treatment, and the correlation of the clinical findings with the pathological picture.

Sgalitzer of the Eiselsberg Klinik has had a large experience in the x ray of the genitourinary tract, and has a great number of very interesting plates. He has devised a method of taking bladder pictures in a semisitting position, in this way obtaining a good view of the posterior wall of the bladder.

In urethroscopy, Glingar, who works with Blum at the Sofienspital, is the recognized leader in Vienna. He has devised a urethroscope which can be used for both the anterior and posterior urethra, and gives excellent courses in the technic of these examinations.

In Vienna, gonorrhea is considered more in the province of the dermatologist than of the urologist, and the great majority of the acute cases especially, go to the dermatologist. To suit better the convenience of the patients, there is a dispensary hour at 5:30 p. m., and a very large venereal material can be seen at that time at both the Finger and Riehl skin clinics.

A man wishing to do original work along any line can easily command the necessary facilities and secure hearty cooperation.

Postgraduate work in Berlin has suffered greatly during the past year on account of the strained economic and political situation of Germany. The American Medical Association of Berlin has been organized for a number of years, but its position is a weak one, many of the Americans working in Berlin not being members. Many Americans have been going to Berlin for the express purpose of securing operative experience, and it is possible to actually do major operative work under good supervision, upon payment of fees ranging from three to five dollars per operation. In view of the present disorganization in Berlin, the consensus of opinion seems to be that other types of work can be obtained just as well in Vienna or elsewhere, and under more pleasant conditions.

Budapest has many hospitals, and in the last year or two has made a direct effort to induce American physicians to come there and pursue postgraduate study. There is a large, well equipped urological clinic under Ilyes, at which a great amount of material is seen, and Americans are received into the clinic upon payment of a fee of one hundred dollars monthly. They are permitted to do a considerable amount of operative work, and it is chiefly for this reason that a considerable number of men have left Vienna for Budapest. Hungarian is the national tongue, but all of the educated classes speak German, and Americans who have gone there only able to speak English have found no difficulty in getting along.

Paris has two large urological clinics, that of Legeu, who is the successor of Guyon, at the Hopital Necker, and that of Marion at the Hopital Lariboisie. There is a great deal of postgraduate teaching done at these clinics but the proportion of Americans is relatively small. All work is given in French, and unelss a man has considerable command of the language, or is willing to spend the necessary time acquiring it, the amount of benefit he derives from these clinics is very problematical. The fees charged for courses in cystoscopy, cadaver surgery, etc., are very small in comparison with those in Vienna, but the groups are much larger, there being twenty-five to thirty men always present at the cystoscopic and urological clinic given by Marion on Tuesday and Friday mornings. Foreigners are not permitted to operate or assist at operations, that privilege being reserved for native Frenchmen.

PARIS LETTER

(From our own correspondent)

PARIS, *August 8, 1924.*

MEDICINE AND THE PRESS

There is one thing that the French papers do better than the majority of those in New York or London—they devote considerable space to medical matters and never fail to report the sittings of the principal medical and surgical associations. Yet they seldom go off halfcock and print accounts of discoveries under sensational headlines before the scientific world has had time to pass considered judgment on the matter. This is particularly the case with reports of events in France; when it is a question of discoveries abroad there is a natural tendency to follow the example of the newspapers in the home country of the discoverer. All of which means that American matters medical get almost as much space in the French press as does French medical news itself. It is to be regretted that daily newspapers should be prone to exaggerate the importance of items of medical information.

A PATHETIC INSTANCE

There came to my attention last year a pathetic instance of the harm that may be done by such exaggeration. The Paris correspondent of an American paper, in all sincerity it is to be hoped, cabled home news of experiments being carried out by a surgeon in the provinces in connection with cases of blindness brought about by war wounds. The surgeon in question had hope of success. The correspondent, adding zest to his story, spoke of realization rather than of hopes. The headline writer at home did his share in the embellishment of the report. And the result was that a doughboy, blinded in the war, came to France with a companion guide who sought enlightenment regarding a certain cabled dispatch from Paris, a clipping of which he jealously kept in his pocketbook. It was pitiful to be compelled to bring disillusion both to himself and to his charge.

REMEDIES FOR TUBERCULOSIS

The French newspapers, taught by experience, are particularly guarded nowadays in connection with announcements of remedies for tuberculosis. It is still reporting and discussing the recent statement by Professor Calmette, brother of the editor of the

Figaro shot down by Mme. Caillaux shortly before the war in 1914, and the seven eminent biologists who have been assisting him in his researches at the Pasteur Institute in Paris, of which he is assistant director. The gist of this statement has already reached America by cable. Nevertheless, it may not be out of place to draw attention to the care with which the researchers iterate and reiterate that they do not claim to have prepared a remedy for tuberculosis, but a preventive vaccine conferring immunity only on individuals who have not been previously infected—very young babes or very young animals. "B.C.G.," as the vaccine is designated, is the outcome of twenty years of research and of experiments on bovines, simians and humans. From fifty to sixty per cent. of the progeny of tuberculous parents have hitherto been doomed to die of the disease within the first two years of life; it is the hope of the discoverers of the vaccine that these infants may all be saved if inoculation be made at once, that is to say, before they are infected by their *milieu*. It is as well to repeat once more that Professor Calmette and his collaborators do not claim to have prepared a "cure." They lay stress on the fact that years of observation will be required before it is possible to assert that the vaccinated offspring of tuberculous subjects are thoroughly immune.

DISEASE ON THE INCREASE

The whole of France has reason to hope that Professor Calmette may be right, for tuberculosis is markedly on the increase since the war. Insufficient nourishment for the inhabitants of the devastated regions, the hardships of the trenches for the combatants, the housing crisis for infants are the principal factors responsible for such increase. Of course no houses were built during the war; since the Armistice virtually all the building has been done on the old battle front, where it was imperative that houses should be set up at whatever cost. Elsewhere, lack of labor and price of materials have handicapped builders. As a consequence many families are living in cramped quarters, for the most part unsanitary, and the number of cases of infantile tuberculosis received in the children's hospitals of Paris is increasing at an alarming rate.

SOME TUBERCULOSIS POINTS

For this and other reasons, tuberculosis is very much to the fore in French medical circles today; several old points of debate have been revived. There is a tendency on the part of some doctors to consider that statistics are swollen by the inclusion of pseudo-tuberculosis. Rist and Ameuille, for instance, incline to the opinion that there are fewer tuberculosis cases than is believed. In their view the only true cases are those of "open" or contagious tuberculosis; indeed they lay down this axiom: "There is tuberculosis only when the expectoration contains bacilli, and there is no tuberculosis when no bacilli are found in the expectoration." This is going back to Koch (1882) and the axiom is the premise for much argumentation. On the one hand, Rist and Ameuille qualify the second portion of their statement by adding that only when absence of bacilli in expectoration has been confirmed "by frequent and methodical examinations" should it be declared that there is no tuberculosis. While Professor Sergent, on the other hand, reminds the doctors that "the fact that no bacilli have been found in the expectoration of a patient does not signify that there have never been any or that there never are any." In other words, the old problem is ever present of the differentiation between tuberculosis of first inoculation (mostly infants) and tuberculosis of reinfection (constant in adults).

CONGRESS AT LAUSANNE

It happens that there has just been sitting in Lausanne (Switzerland) the congress of the International Union Against Tuberculosis, attended, among others, by Dr. Stephen John Maher, of New Haven, Conn. The delegates discussed the Koch bacillus in its every detail, with particular reference to the point whether there exists any real relationship between the said pathogenic bacillus and the para-tuberculous bacilli commonly met with in the most diversified *milieux* outside of tuberculous organisms. The French scientists at the congress were inclined to hold that laboratory experiments have furnished no formal proof of identity of species, or even of close relationship, between the two categories of microbes in question; generally speaking, the French view was that tuberculous contagion in man is produced only through the intermediary of the authentic bacillus and that the neighboring species, although related, have no real pathogenic power. Dr. Maher attracted considerable attention by his expression of the view that there exists in Nature or that it is possible artificially to create saprophytic forms of Koch's bacillus susceptible of transformation into virulent tuberculous bacilli. Dr. Maher affirms that it is possible for acid fast bacilli, one at least of which is naturally present in every human body, to be transformed into the true tubercle bacillus as a result of injury to the tissues or of irritation thereof.

STATISTICS CHALLENGED

This letter, already too long, could be made much longer and yet fail to treat of a tithe of the subject. For instance, Sir Robert Philip, reading at Lausanne a paper in such excellent French that it surprised greatly all the French speaking delegates, urged that consumptive cases must be sought for by those interested in preventing the spread of the disease instead of waiting until cases present themselves. And he gave figures concerning the British Isles. On this very point of statistics there is considerable controversy in France. Common sense tells us that statistics are utterly valueless unless the identity and capability of the statistician are given, together with his or her figures. (Incidentally, I may state from personal experience in the Army that, in many instances, figures, however official, may be rejected on principle. When you ask a doctor, at three hours notice, to supply statistics of the health of an entire garrison town for a period of twelve months or more, you cannot expect accuracy.) The French, ever logical, demand an international standard for the establishment of statistics relative to tuberculosis or any other disease if trustworthy comparisons are to be established. They incline to the opinion that diagnosis nowadays is too sweeping and that of the inmates of sanatoria too great a proportion consists, not of tuberculous but of pretuberculous subjects, who are not bacillus carriers and may never be.

LATIN AMERICA LETTER

(From our own correspondent)

CANAL ZONE, *June 1, 1924.*

SANITARY PROJECT AT GUAYAQUIL, ECUADOR

The Congress of Ecuador by a decree, enacted September 29, 1923, created a special sanitary board for the City of Guayaquil. This body has as its function the supervision of the paving of the streets and the installation of sanitary drainage and water systems, and replaces the Executive Power and the municipality in the contracts already let for works of a similar nature. The board, which consists of seven members, began its labors on January 1, 1924. It is authorized to contract a loan of £2,000,000 to be guaranteed by revenues set aside by Congress for this purpose. This project, in connection with the very excellent sanitary work which is being done by the National Health Officer, Dr. Wenceslao Pareja, will do much to advance the health of Guayaquil and improve economic conditions in Ecuador. Guayaquil, the principal port of the Republic, was once one of the great world centres of yellow fever. The disease was eradicated by Dr. M. E. Connor of the International Health Board, but bubonic plague remains and malaria is very prevalent at certain seasons of the year. Situated on the Guayas River, some thirty miles from its mouth, Guayaquil occupies a low plain which is drained with difficulty, particularly in the rainy season. This favors the propagation of the Anopheles mosquito, and hence the spread of malaria. The new project aims to make Guayaquil one of the most healthful ports in South America.

WATER SUPPLY FOR GUATEMALA CITY

The Acatán water works which were badly damaged by the earthquake of six years ago, are to be further repaired in order to improve and increase the water supply of Guatemala. The reservoir, which is eighteen kilometres from the source of supply, is to be connected with it by concrete piping. The water supplies of Acatán Las Minas and Pinula are to be carried to a large reservoir at Santa Faz. Iron piping will be used for water distribution.

GUATEMALA'S POPULAR UNIVERSITY

To combat illiteracy, improve social education, awaken initiative, and teach the principles of personal health, hygiene and sanitation, the Republic has founded the Popular University, to be situated in Guatemala City. The Minister of Public Instruction has selected two teachers to study in Belgium and one in the United State, in order to acquire new methods and ideas for adoption in Guatemala.

CHILDREN'S BUREAU FOR ARGENTINA

By Presidential decree there has been added to the National Department of Hygiene of Argentina, the Children's Bureau, to study infant mortality and diseases, the protection of motherhood, school hygiene, child homelife and child labor—in fact, everything relating to child welfare. It will also plan and stimulate the formation of social organizations for child protection and assistance, and coordinate all agencies having aims related or similar to those of the Children's Bureau.

LIMA TO BUILD CHILDREN'S HOSPITAL

The proceeds of a tax on alcoholic liquors will be used to establish and maintain the Children's Hospital, which the Society of Public Charities and the Child Welfare Society propose to build at Lima, Peru. On every litre, or fraction thereof, of native beer, wine or spirits, a tax of one centavo has been imposed by a law recently enacted by the National Congress. The tax on imported alcoholic beverages is two centavos a litre, and the fund for the new hospital is further augmented by a duty of ten per cent. on the quarterly payments of the municipal sales tax on liquor sold at retail. A similar law creates a special tax of forty centavos on every one hundred kilos of Portland cement imported through the Callao custom house. The funds thus raised will be used for building the Arzobispo Loaya Hospital. Upon completion of the hospital, the tax will be abolished.

LONDON LETTER

(From our own correspondent)

LONDON, *July 29, 1924.*

CONFERENCE ON INFANT WELFARE IN LONDON

The third English speaking Conference on Infant Welfare was held at Caxton Hall, Westminster, London, on July 1, 2, and 3, 1924. The president was the Rt. Hon. John Wheatley, M.P. The conference was preceded on Monday evening, June 30th, by an at home at the Forum Club, on the invitation of the Public Service Section which was largely attended, many overseas delegates being present, followed on Friday, July 4th, by visits to various child welfare institutions. More than seven hundred delegates, representing local authorities, child welfare institutions and governments of thirty different English speaking countries attended.

At the opening session on the morning of July 1st, the chair was taken by Dr. G. F. Still, chairman of the National Association for the Prevention of Infant Mortality and of the National League for Health, Maternity and Child Welfare.

The inaugural address was delivered by the Rt. Hon. John Wheatley, the Minister of Health. He said in part that the care of the mother was the first consideration. It was not satisfactory to find that there had been little reduction in the maternal mortality during the past thirty or forty years. It was a matter of grave concern to many competent observers of social life, and it was one which was engaging the closest attention of the Ministry of Health at the moment. There was no doubt that much of the mortality that obtained was of a preventable nature, and it was the duty of a conference of this kind to pool its experiences and opinions in a national and international effort to ascertain the means by which this prevention could be secured because the fact had to be borne in mind that it was not merely the mortality but the amount of suffering and of misery at present associated with motherhood.

The Ministry of Health hoped that one result of the School Medical Service which was now growing up would be to make young women and girls better fitted physically for the burden and task of maternity.

Book Reviews

THE HOSPITALS OF NEW YORK

The Hospital Situation in Greater New York. Report of a Survey of Hospitals in New York City by the Public Health Committee of the New York Academy of Medicine. Prepared by E. H. Lewinski-Corwin, Ph.D. With Illustrations. New York: G. P. Putnam's Sons, 1924. Pp. 356.

This volume represents the fruits of a survey of hospital services in the City of New York, conducted by the Public Health Committee of the New York Academy of Medicine. The study was undertaken because of the fact that although there has been a very rapid growth of hospital accommodations in the metropolis, it has been a growth unguided by a community policy concerning the need for further services and for the better adjustment of existing facilities to the requirements of the city. The magnitude of the investigation is evidenced by the fact that ten per cent. of all hospital beds in the United States are maintained in New York City in institutions varying in size from 25 to 1,830 beds; and that it costs thirty-five million dollars annually to maintain these institutions. Because of the scope and diversity of hospital services in New York, this survey is of value to all those interested in hospitals throughout the country.

An historical sketch of the development of hospitals in New York introduces the reader to the subject under consideration. In the following chapters every detail of hospital administration, and the varied relationships of the hospital to the community are discussed on the basis of facts gathered from a first hand investigation of the many institutions of the greater city. A wealth of material is presented which can hardly be touched on in a brief review.

Thirty-nine per cent. of the total hospital capacity of the city is found in the eighteen municipal hospitals; fifty-seven per cent. in the 114 privately endowed hospitals; and four per cent. in the fifty proprietary institutions. There are thirty-two thousand beds in all, or one bed to about every 175 of the population. The absolute number of beds is sufficient, but further analysis of the services offered shows that these beds are not all used to the best advantage. For the year 1920 the average utilization of hospital beds in the general hospitals was 70.6 per cent.; the privately endowed hospitals had an average of 73.2 per cent., and the municipal 67.3 per cent. New York has a large and heterogeneous accumulation of hospital services more or less suited to the needs of the community, but inelastic in their organization, not fully adjusted to meet the economic status of the several classes of the population, and for the most part not coordinated with existing hospital facilities in the city as a whole. Thus while certain classes of patients are well provided for, for others such as neurological cases and most chronics the accommodations are insufficient and often inadequate. There is no provision whatsoever for a psychopathic diagnostic hospital.

Such a situation calls for intelligent planning and cooperation. A part of the existing municipal hospital accommodations could profitably be diverted and equipped to meet some of these wants. At present the city is competing with the private hospitals and withdrawing a good part of the financial support which it has given in the past to the private institutions. There is sufficient opportunity for service for all of the existing institutions if they cooperate in defining the scope of their work.

The reviewer has chosen this phase of the hospital problem as one of the most interesting ones. A careful perusal of the book will throw light on many other matters, and should provoke much stimulating thought. Thanks are due to Dr. Corwin for his vast labor in compiling all of this information, and presenting it in a readable and attractive manner. The book is well printed and bound and has many interesting illustrations and graphs.

TROPICAL DISEASES

Handbuch der Tropenkrankheiten. Unter Mitworkung von Prof. Dr. U. N. Brahmachari. Herausgegeben von Prof. Dr. Carl Mense-Kassel. Dritte Auflage. Erster Band. Mit 341 Abbildungen im Text, 7 schwarzen and 5 farbigen Tafeln. Leipzig: Verlag von Johann Ambrosius Barth, 1924. Pp. xviii-713.

To those interested in tropical diseases the third edition of this manual should be a source of joy. It is the most complete and up to date manual on the subject. In the first volume A. Eysell treats the subject of the activity of arthropods, first as carriers of disease and then as cause of disease in the human being. Every form of this type of animal life is discussed in detail, including their anatomy and habits of life and their special characteristics, which aid in their recognition. In the second part of the book V. Schilling discusses the application of hematology to tropical diseases in all its branches from the taking of the blood from the patient to the interpretation of the blood findings. The bibliography is most comprehensive and includes the literature of the world. The illustrations are very numerous and well selected and the colored plates are works of art. The authors and publisher are to be congratulated on the production of this work as it leaves little, if anything, to be desired.

NOSE, THROAT AND EAR

Diseases of the Nose, Throat and Ear for Practitioners and Students. Edited by A. Logan Turner, M.D., F.R.C.S., et al. With 222 illustrations in the text and twelve plates, of which eight are in color. New York: William Wood and Company, 1924. Pp. 413.

The difficulties encountered in presenting a special subject to the general medical reader in a popular and easily comprehensible way are many and various, and we know of but very few writers who have successfully overcome them. The authors of the present volume, which is a rewritten and reconstructed work of a presumably popular book in England whose former author died in the service of his country, have to a great extent succeeded in meeting the requirements that the general practitioner will demand of his textbook on a specialty: clarity of exposition, avoidance of nonessentials, and treatment of those affections which he is most likely to meet in his daily work. The problem of compressing within the space of four hundred pages all

that may be of interest to such a reader, in the domain of the ear, nose and throat, had been solved by alloting sufficient space to subjects that are of comparatively frequent occurrence, and by treating items that are of interest only to the specialist in a short, concise and terse manner. Thus the various sinusites, the importance of which in the pathology of the ear, nose and throat is gradually coming to be recognized at the present day, are justly treated in an exhaustive and thoroughgoing manner, and the same may be said, though to a somewhat lesser degree, of the subject of the tonsil, its inflammation and surgical treatment, that of tuberculosis of the larynx, of diseases of the external meatus, which usually fall first into the hands of the general practitioner, acute and chronic middle ear suppurations with their consequences, and so on. An interesting feature of this work is an illustrated clinical anatomy of the respective regions which the editor hopes will enable the student to obtain all the information which he may desire upon the applied anatomy of the different organs. We were among other things particularly impressed by the chapter on the physiology and functional examination of the ear, where these somewhat complicated subjects are taken up and elucidated in a clear and practical manner.

We can heartily recommend this book, not only to the general practitioner who wants to keep abreast of new advances in the field of the ear, nose and throat, but also to the specialist who is sure to peruse its well written pages with pleasure and profit.

MAYO CLINIC PAPERS

Collected Papers of the Mayo Clinic and the Mayo Foundation. Edited by Mrs. M. H. Mellish. Volume XV, 1923. Published June, 1924. 410 Illustrations. Philadelphia and London: W. B. Saunders Company, 1924.

This volume marks a departure in the method of presenting the work of the Mayo Clinic in the form of wellknown *Collected Papers.* The number of articles published annually from the Clinic has become so large that in recent years it was found necessary to omit some of them entirely from the volume of reprints. The present volume, however, contains all the papers either in full, abridged, or by title. It is therefore a complete and accurate guide to the work done in this leading medical centre. The papers mentioned by title only are those of less general importance or interest.

The 1923 volume is the work of 148 contributors from the Mayo Clinic and the Mayo Foundation. The subject matter is presented under nine main heads. The alimentary tract leads all other subdivisions with fifty-two papers. The next largest subdivisions are urogenital organs; and head, trunk, and extremities, each with thirty-two papers. The blood and circulatory organs are represented by twenty-four papers and the ductless glands by twenty-one papers. The other general subjects covered are: Brain, spinal cord, and nerves; skin and syphilis; and technic. There are also twenty-two papers in a group labelled general miscellaneous. Here are included articles on medical education, medical organization and hospital administration and management.

It is impossible in reviewing a book of this size (it contains 1420 pages and 209 separate papers) to mention in detail any special articles. Suffice it to say that the topics selected for presentation are of the widest diversity and of great interest and value to all physicians. Even the human side of practice is not forgotten as is seen in the somewhat sentimental title, How Is the Overworked General Practitioner to Use Insulin? The volume is completed by an excellent bibliographic index and index of subjects.

MATERNITY NURSING

Maternity Nursing in a Nutshell. By Elizabeth H. Wickham, R.N. With Twenty-eight Illustrations. Philadelphia: F. A. Davis Company, 1924. Pp. viii-167.

This is a handy little reference book which easily fits into the nurse's obstetrical bag, to be used in an emergency. Its chief value lies in the many practical hints that are of value to the nurse in charge of an obstetrical case. The important points in prenatal nursing care, dressing and outfits, preparation for delivery in the home, delivery by the nurse, postpartum care of the mother, care of the baby, infant feeding and on complications of the puerperium are well brought out and duly emphasized. An appendix contains some helpful hints and also tables of measurements. A glossary is also added.

WEIGHT CONTROL

Eat Your Way to Health. A Scientific System of Weight Control. By Robert Hugh Rose, A.B., M.D. New Edition. Thoroughly Revised and Enlarged. New York: Funk and Wagnalls Company, 1924. Pp. 230.

This little book is of value because it contains detailed menus of three kinds: for weight maintenance at any given level, for weight reduction, and for weight increase. Under each group menus are given every day for two weeks for both summer and winter. The calories of each portion are indicated as well as its content in the principal vitamines. The text is clear and sensible and includes complete height-weight tables for both sexes. The book can safely be recommended to the laity and should prove helpful to the physician who prescribes diets as a part of his daily routine.

COSMETIC SURGERY

Cosmetic Surgery. By Charles Conrad Miller, M.D. With 140 illustrations. Philadelphia: F. A. Davis Company, 1924. Pp. 263.

If one approves of cosmetic surgery this seems about the best treatise that has been produced. It is very well illustrated with drawings and adequate descriptions. The reviewer believes that certain types of cosmetic surgery are justified if the patient so desires. There is no question that in any type of cosmetic surgery about the face there is a certain risk, but if the patient understands this and is willing to take it in order to attempt an improvement in personal appearance, the procedure is justified.

MICROBES

Fighting Foes too Small to See. By Joseph McFarland, M.D., Sc.D. Philadelphia: F. A. Davis Company, 1924. Pp. 309.

This book seems to have accomplished in almost the ideal way the discussion of a technical subject without sacrificing scientific accuracy for popularity.

ANATOMY OF BONES AND JOINTS

A Descriptive Atlas of Radiographs of the Bones and Joints for Students and Practitioners. By A. P. Bertwistle, M.B., Ch.B. With 299 Illustrations, All Radiographs. New York: William Wood & Co., 1924. Pp. 197.

This work gives a complete view of the normal and pathological anatomy of the bones and joints. It lacks only the almost microscopic details of structure which can only be obtained in actual photographic prints. Two hundred and ninety-nine of these would make a costly volume. And except in a few cases what might be called the gross pathology demonstrated in this book is ample.

The radiographs themselves are strikingly effective; the bones are black or gray, the flesh white, silhouetted upon a black background. This effect is recommended for photographic prints when the negative cannot be sent to the surgeon. Upon the negative the outline of the flesh is scratched, on both sides if the film is double coated, and the resulting print shows the gray or black bones with a black line marking the outline of the flesh. Beyond this the background of the print is filled in with India ink. The bones stand out unusually well and the silhouette of the flesh answers many purposes of an ordinary photograph.

An ample diagnostic note accompanies each radiograph. The paper is excellent and the screen employed in making the illustrations is so fine as never to be noticeable and is only discoverable by the closest scrutiny.

Among the radiographs are a complete series of normal ones; also fractures, dislocations, deformities, complications of amputation stumps, atrophy, myositis ossificans, syphilis, tuberculosis, tabes, tumor, and many others. The surgeon certainly needs such a guide and this book is to be highly recommended. The fine glossy paper, brilliant black ink and exceedingly fine screen make this the best large collection of half tones of radiographs the reviewer has seen.

SURGERY

Surgery of the Spine and Extremities. By R. Tunstall Taylor, M.D., F.A.C.S. With 604 Illustrations. Philadelphia: P. Blakiston's Son & Co., 1923. Pp. X, 550.

The author of this volume has admirably carried out his purpose in preparing a practical work for those who are engaged in the field of orthopedic surgery. It not only presents the subject in a practically concise manner for one who would survey the field briefly or for the student who would first enter it, it is also, as the author intended, of great value to those who must intelligently assist the surgeon here. Taylor writes with the authority of one who has a comprehensive knowledge of his subject from long familiarity with its practical phases. He broadly considers it in the light of its widest relationships in etiology, pathology, and the possibilities of readjustment and reconstruction. He enters carefully into the difficulties and the mistakes that may arise in the application of appliances as into the various therapeutic possibilities of any of the surgical procedures undertaken. There is a brief definition of orthopedic surgery together with a review of its history from ancient to modern times. Space is given to the discussion of various forms of apparatus and their preparation. The greater part of the book is devoted more definitely to spinal disorders and to other special disorders such as infantile paralysis, various muscle syndromes, joint disorders, etc. The author has endeavored to put into this concise practical form the wealth of material which has been developed in this field through the impetus of the late war, as well as through the steady advance in methods which belongs to the normal progress of the day. The author's own experience has contributed its share in this advance. He has here made available much that will increase the equipment of the student and the worker in this field. The many illustrations bring the matter of the text to an even more applicable form of clearness.

HYSTERIA

Uber Hysterie. By Dr. Ernst Kretschmer, Privatdozent für Psychiatrie in Tübingen. Leipzig: Georg Thieme, 1923. Pp. viii—115.

Kretschmer's new study of hysteria presents the subject in its dynamic nature. It takes the view of some hidden purpose driving to instinctive rather than rational reactions and thus making use of ancient phylogenetically prepared pathways. The reaction is childish, primitive, yet it takes place in a complex civilized human being and therefore cannot be as simple as in the animal or child. A complicated mechanism must intervene to make possible the carrying out of the hidden purpose in all its dominance over the higher will. Kretschmer has examined this mechanism in detail in relation to the manifestations so common as a result of war shock as well as in peace hysterias. He believes that there is a period when a primary reaction to the trauma, such as tremor, is slightly strengthened voluntarily but that this is soon veiled from the patient and then the situation, aided by repression, becomes "objectified" in a form which seems to be entirely beyond the patient's control. Kretschmer also follows out the more elaborate psychic complications which build themselves over this mechanism thus simply stated and through which the patient obtains a compensatory substitute for the reality he has feared and rejected or by which he more directly defends himself against. Kretschmer sees in hysteria this intrinsic defense reaction. He is not ready to follow Freud all the way in the extension of the term sex and in the psychoanalytical recognition of the unconscious content operative in hysteria. Yet in general principles his view is much the same.

THE LACUNAR SYSTEM

Aperçu de la Physiologie dt de la Pathologie générales du Système lacunaire. Par Ch. Achard. Paris: Masson et Cie, 1924. Pp. 124.

The author of this monograph groups together under the terms "lacunar system" the aggregate of unconnected cavities in which is enclosed the greater part of the fluid of the body. In both ontogeny and phylogeny, this system precedes in its appearance the blood vascular and lymphatic systems, which, as a matter of fact, are merely auxiliaries to the lacunar system. In man, this system comprises the intercellular spaces, connective tissue spaces, subarachnoid spaces, the humors of the internal ear and eye, and all the serous cavities, large and small. The author presents a study of the formation of serous fluids,

he nutritive rôle of the lacunar system and the relationship of proper physicochemical stability of the acunar fluids to the activity of tissue cells. The effects of inflammation and other morbid states on he lacunar system are also discussed. From the herapeutic viewpoint, the action of various measures through the intermediation of the lacunar system is explained, especial attention being paid to the influence of restriction of salt and of water on this system. The latter measures, the author holds, are based wholly on the physiology of the lacunar system. A number of clinical observations and diagrams are adduced to illustrate the value of a more precise knowledge of the lacunar fluids in the treatment of disease. Analyses of the various fluids are presented in an appendix. This monograph cannot fail to be suggestive and interesting to all who are engaged in the clinical or pathological study of renal or hepatic diseases or of the metabolic diseases.

ATLAS OF MALE BODY

Baillière's Popular Atlas of the Anatomy and Physiology of the Male Human Body. By Hubert E. J. Bliss, M.A., M.D., Cantab., D.P.H. Third Edition. Plates by Georges M. Dupuy, M.D. New York: William Wood and Company, 1924.

This is the third edition of this popular atlas. The plates, which are by Georges M. Dupuy, are preceded by a description of the anatomy and physiology of the male body by Hubert E. J. Bliss, and a guide to the plates. The atlas is printed in Great Britain.

The eight sets of plates, the majority of which are in colors, include the usual groupings of the organs of the human body: Bones, muscles and articulations, viscera, vascular, nervous, and respiratory systems, the eye, the ear, urinary and genital organs, and prominences and motor points of nerves and muscles.

The plates and charts are exceptionally clear and detailed as is characteristic of British medical reproductions. Bliss's prefatory essay on the male human body is complete without being involved or too detailed, and is written in a clear and interesting manner.

PATHOLOGY OF THE RESPIRATORY APPARATUS

Nouveau Traité de Médecine. Fascicule XI Pathologie de l'Appareil Respiratoire. Paris: Masson et Cie., 1924.

This is Fascicule XI of a new treatise edited by the leading clinicians of the French faculties of medicine of Paris, Lyons, Nancy, and also by a few distinguished graduates of the Paris school now residing in foreign countries. The twenty-two volumes, covering the entire field of medicine, are published under the direction of Professors G. H. Roger, Fernand Widal and P. J. Teissier, all three of the Paris faculty.

The volume before us treats of the respiratory apparatus, that is to say, the nose, larynx, trachea, bronchial tubes and the lungs. This book is divided into six chapters: Bezancon and de Jong describe first the entire symptomatology of the respiratory apparatus; Bourgeois speaks of the pathology of the nose and larynx; Bezancon and de Jong of the trachea and the bronchial tubes; Hutinel and Paisseau of bronchopneumonia, and Hervier of the pathology of pulmonary congestion, acute oedema, gangrene, abscesses, and lobar pneumonia, embolism, pneumoconiosis and atelectasis of the lungs. Lastly, Ribadeau Dumas describes the neoplasms of the pleura and lungs and hydatic cystes.

Numerous illustrations and a number of beautifully colored plates and also some x ray photographs make the volume an unusually valuable one for the student, the general practitioner and also the specialist. All that is known up to date of the etiology and pathology, and perhaps also of the treatment, can be found in this book written by men of large experience and acknowledged as authorities. The only important omission in the therapeutics of bronchiectasis and lung abscesses the reviewer could find was the important advancement in the management of such cases by the use of the bronchoscope. When one has seen the results obtained by Chevalier Jackson, of Philadelphia, and his disciples in the treatment of bronchiectasis and lung abscesses, one cannot help regretting that our French colleagues in their latest treatise on the subject have failed to mention this new valuable method in washing out the bronchiectasic cavities and cleaning of abscesses. Aside from this criticism one may well consider Volume XI of the *Nouveau Traité* as complete a contribution to the subjects mentioned as is possible with our present knowledge.

MICROBIOLOGICAL TECHNIC

Handbuch der mikrobiologischen Technik. Band II and III. Edited by Dr. Rudolph Kraus and Dr. Paul Uhlenhuth. Berlin and Wien: Urban & Schwarzenberg, 1923 and 1924.

Volume II is devoted to special technics regarding bacterial cultures, staining methods, and chemical products. One section deals with the bacteriophage problem. Among other topics of interest treated are the physicochemical foundations of microbiological methods, a long chapter on the detection of infectious diseases from the point of view of the veterinary surgeon, another on the methods of infecting and testing animals, rules for the conduct of bacteriological laboratories, methods of shipping cultures, and suggestions as to the proper way of removal or incineration of dead animals.

Volume III is concerned with moulds, filterable organisms and viruses, directions for the cultivation, preparation, and study of insect vectors, and strange to say, twenty pages on the methods of investigating tumors. One chapter is on the general arrangement of microbiological institutions, including mobile laboratories, with examples drawn from the American field equipments which were used during the war.

INSTRUCTIONS FOR THE SURGEON'S ASSISTANTS

The Operating Room. Instructions for Nurses and Assistants. By the Staff of St. Mary's Hospital, Rochester, Minnesota—The Mayo Clinic. With 144 illustrations. Philadelphia: W. B. Saunders Company, 1924. Pp. 165.

This is a little book published by the Mayo Clinic for the purpose of instructing nurses and assistants in the operating room procedures. It is a handy volume as it gives the routine instruments and preparations for various standardized procedures.

PHYSICAL FREEDOM OF WOMEN

Woman's Physical Freedom. By Clelia D. Mosher, M.D. New York: Woman's Press, 1924.

The author of this interesting little book is associate professor of hygiene and medical adviser of women at Stanford University. The theme of her book is that any healthy woman's lessened efficiency is probably due to some anatomical handicap that can usually be compensated for by certain regular practices and exercises. Her treatment of the subject includes discussion of the menopause, dress and personal habits, the psychic side of periodical and chronic invalidism, and a good deal of excellent advice, rather dogmatically put.

The treatment of the subject is distinctly for the lay person and so nontechnical in style, but Dr. Mosher writes from a truly scientific basis and with a wholesome and refreshing clarity and frankness. The book is not at all theoretical, but the result of her own personal application of hygiene and medicine to practice among women.

THE DOCTOR IN FICTION

The Avalanche. By Ernest Poole. New York: Macmillan Co., 1924.

Our chief quarrel with this book, which is on the whole not as distinctive a product as Mr. Poole's other works, is that the author has allowed his hero to fail so miserably in his profession. Granted that the emotional bond between Llewellyn Dorr and wife Dorothea, blinds them both to a degree, nevertheless they realize her pathological condition and have easy access to its cure. Naturally her husband cannot treat her, but any psychoanalytic husband with a wife whose vagaries threaten his life and happiness (as well as hers) should be able to induce the wife to visit some other analyst.

The lady in question is selfseeking. Her only happiness lies in being in the thick of some activity that is going to cover her personally with glory. She takes up the brilliant young doctor as a diversion from the problem she is trying to avoid, a decision concerning her future life. The owner and editor of *The Chronicle,* the man whose life corresponds with the heart of her interests, is impatient for his answer. She has held him off interminably, until she is exhausted with indecision. The realization that she will have to share, is, we believe, the barrier beyond which she cannot go. She wants to be in the spotlight entirely. As the editor's wife, the paper and the man himself will invariably be dragged into any triumphs she may have.

Young Dorr cures her of the breakdown resulting upon this crisis. They are "intrigued" by each other. And presto, Dorothea, who thought life held no more novelties for her, is off on a new track. They marry. Promoting the doctor offers a big field. She feels she can raise him to her snobbish level if she pushed him the way she and *The Chronicle* between them can. The man being a true scientist, rebels, but it is too late. The avalanche has been let loose. It buries him. Dorothea escapes, unscathed as is the way with selfcentred people, and the patient editor wins her in the end.

Life is like that of course. The mischief makers never seem to draw their deserved punishment. The fools who mean no harm invariably get the better of honest effort, genius. And genius is especially prone to nourish its own narcissistic strain, to take mistakes too hard, and to give up life rather than admit defeat and start again.

The *deus ex machina* in the doctor's case is a war weakened heart. The strain of the ordinary professional life might have brought the end at any time. Only his marvellous will pulls him through the long bout of psychic strain of the peculiarly senseless life he lets Dorothea lead him. When the last incentive to live is lost, he passes mystically out of the picture, paying her narcissism a final tribute. He could not live without her!

There are numerous warnings to be gleaned from this book. One is "Don't marry a genius." Another is "Don't marry a restless society striver." Altogether it is a series of "don'ts." We wish the time would come when authors would not make Death the only thing to "do."

Medicoliterary Notes.

The Nobel prize winner in physics this year was Prof. Calvin S. Page, of Chicago, for his book entitled *Rex, the Life Atom.* In his book Professor Page turns the gravitation theory inside out, maintaining that instead of attraction there is antipathy among physical elements. He explains radio vibration as "superlight" or as color beyond the visible spectrum. In his theory of a universe, sound is also light, there is no ether, the orbits of the planets are not elliptical but circular, and there is no gravitation but, instead, repulsion.

The New York Botanical Garden has received the most important collection of books on botany and horticulture that has ever come to this country from Europe. It was purchased from the Geneva Botanical Garden, and includes five thousand bound volumes and many more pamphlets and unbound works.

* * *

The Ethics of Opium is the title of an interesting and valuable little book by Ellen N. La Motte, recently published by the Century Company. Miss La Motte has devoted many years of her life to investigating and fighting the drug menace and the purpose of her present book is evidently the exposition from authentic sources of the international situation as well as of conditions in the individual countries. She has presented for our consideration an impressive mass of facts, statistics, accounts of conditions, and other data. Her main contention is that there is only one way in which the menace can be ended—reduction of the amount of raw material produced to the bare limits of what is needed for purely scientific and medical uses.

* * *

The History of Human Marriage by Westermarck, originally issued in three volumes, has been abridged and revised and will be a forthcoming publication of Macmillan. It will be in one volume and has been put in more popular form than previous editions.

* * *

The menace of the critic, if there is one, to the popularity of theatrical productions, has apparently been partly solved at least by French managers and producers. During the past season the general public has been given the first taste of the new plays and a chance to manifest pleasure or displeasure independently of newspaper criticisms. Invitations to critics are not sent out until after the third or fourth performance.

Charles Darwin once set a musician to play in his greenhouse to ascertain whether music affected plants.—*Havelock Ellis in The Dance of Life.*

* * *

The Playground and Recreation Association of America has recently issued with Macmillan as publisher an interesting handbook on summer camps and camping entitled

Camping Out; a Manual on Organized Camping. There are chapters on all the problems of summer camping written by authorities on the various subjects. The book should be of unusual value to camp organizers and directors.

* * *

One of the best novels of American life published in recent years in Edith Kelly's *Weeds.* It is a realistic yet sympathetic study of the life of the socalled "hill-billies" of the Kentucky and Carolina foothills, a region and people that have been usually written about either in a sentimental vein or from the point of view that they are objects of charity. Miss Kelly shows them as they are.

* * *

Many an American advertiser has come to grief by not knowing what the English call things. . . . Don't ask for a drug store if you are taken sick in England or you may be suspected of being a drug fiend. . . . A drug store in England is a "chemist's shop." A "store" isn't a store, it is a warehouse. Drygoods are not sold in drygoods stores, they are sold in "draper's shops," and they aren't called drygoode either, they are "drapery" or "mercery." Candy isn't candy, it is "sweets" or "lollies"; peanuts are "monkey nuts"; a monkey wrench is a "spanner"; suspenders are "braces"; wood alcohol is "methylated spirits"; cotton is thread, not raw cotton. When an English business man telephones, he doesn't say "hello"; he says, "Are you there?" He uses cheques, not checks. He calls a chiffonier a "chest of drawers." A dresser is not a dresser but a piece of furniture on which to put china and plate, after it has been "washed up" in the kitchen. If he sells spinach, he is a "green grocer"; if he deals in chickens, he is a "poulterer." —*New York Times.*

* * *

A very entertaining little book is *Magic for Amateurs,* by W. H. Radcliffe (Appleton). About fifty tricks are explained and illustrated, such as how to make an "enchanted cabinet," "mental telepathy," "spirit" slate writing, and how to juggle entertainingly with cards, eggs, toothpicks, and matches.

* * *

The University of California has taken a step toward correcting the "divorce evil," if such it be, by instituting a course in critical analysis of the home. Miss Mary Burt Messer, formerly of the sociology department of the University of Wisconsin, is director of the course. Miss Messer has been quoted as saying that the troubles of American home life fall into two main categories: "the belief on the part of the modern young woman that she is indifferent to the ties of love and of home"; and "the insufficiency of the home itself, its mediævalism and inability to meet the needs of the present day man, woman, and child."

* * *

Lucien Fabre, who has been called the twentieth century Balzac because of his brilliant style, has been awarded the Goncourt prize for his novel *Rabeval.* M. Fabre is not a writer by profession, but began life as a factory hand. Later he became an engine driver, and adopted this as a profession. Recently he has been working with an aviation firm. His novel is in three volumes and describes the gradual development of the boy of a Parisian laborer into a great financier.

Albert and Charles Boni have announced that one of their early fall publications will be a hobo autobiography by Jim Tully, entitled *Beggars of Life.*

* * *

Three very revealing studies of the younger generation in Europe were quoted in the *Living Age* recently. These are an account of how the French girl faces marriage, by Marcel Prévost, from *Figaro;* comments on the new generation in Austria, by Bertha Pauli, from the Vienna *Neue Freie Presse;* and an account of the New German Youth Movement, by Meyrick Booth, from the London *Nation and Athenaeum.*

* * *

Reading Gaol, the prison immortalized by Oscar Wilde's *Ballad of Reading Gaol,* is to be demolished to make room for modern apartment houses. It was in this jail that Wilde was imprisoned and where he wrote *De Profundis.*

* * *

A recent English publication of interest is entitled *Love Letters of Great Men and Women,* collected, translated, and arranged by C. H. Charles in groups of countries, periods, régimes, etc. The book has an entertainingly written preface on the lost art of letter writing, and the qualifications of the ideal love letter. The writer believes that the art of writing love letters is a lost one, and proposes that we try to revive it by instituting courses in the schools.

* * *

As a tribute to the activities of the American Relief Administration, the word "ara" meaning to "give in love and charity" has been incorporated into the Russian language.

* * *

The *Yale Review* for July contains a number of articles of unusual interest, among them The Feminine of Genius, by Clemence Dane, a discussion of whether or not woman is capable of genius; a study of Byron and his poetry by Howard Mumford Jones; Are Acquired Characteristics Inherited? by T. H. Morgan; Locking the Barn Door, a discussion of marriage especially for the young and unmarried, but of interest to all; and an unusually full book review section.

* * *

Recent novels that make interesting reading are: *Black Laughter* by Llewellyn Powys, sketches of the life led by African ranchers; *Nightshade* published anonymously by Dutton, a frank but understanding story of American small town life; *The Wrath to Come* by E. Phillips Oppenheim of interest to those who like his frantic plots and sensational style; *Waste* by Robert Herrick, dull in spots but interesting as a whole as an honest and understanding portrayal of life during the last half century in the United States: *La Dame de Sainte Hermine* by Grace King, a story of the growth of New Orleans; *Back Stage* by Roland Oliver, playwright, a story of a theatrical company of Greenwich Village; *My Life,* a small book purporting to be an autobiography, but by some thought to have been written by Tolstoi; the story was supposedly told by a Russian peasant woman to Tolstoi's sister-in-law, who took it down as the woman talked, and gave the manuscript to Tolstoi to edit; *Wandering Stars,* a mystical tale by Clemence Dane well done but not up to her usual standard; *Epithalamium* by Jacques Chardonne, which won the Northcliffe Prize and which is an exquisite picture of married life translated from the French (Doran); *Roughneck,* a typical novel by Robert W. Service; *Isle of Thorns* written in Sheila Kaye-Smith's characteristic style; *Gold* by Jacob Wassermann, the story of a masterful German woman who dominates two generations of a Viennese family; *Impromptu* by Elliot H. Paul, an exposition of the sometimes abnormal psychology of the returned soldier, which opens with tremendous strength and beauty but unfortunately descends toward the close to a long drawn out case study of a syphilitic; *The Singing Season* by Mrs. Isabel Patterson, an excellently written romance of life in Cordova; *The Two Coyotes* by David Grew, the story of a Western hermit nicknamed "the Coyote" and of a real coyote; *Soul Enchanted* by Romain Rolland, the study of a woman's life in three volumes, like *Jean Christophe,* of which the first volume was published this summer; *Redcliff* by Eden Phillpotts, a story of the Devonshire coast; and *Balisand* by Joseph Hergesheimer, *The Tatooed Countess* by Carl Van Vechten, *A Pilgrimage* by Johan Bojer, *Blind Rafferty* by Donn Byrne, *Men, Maids and Mustard Pot* by Gilbert Frankau, *East of the Setting Sun* by George Barr McCutcheon, *Anthony Dare's Progress* by Archibald Marshall, *The Priceless Pearl* by Alice Duer Miller, *Golden Ballast* by H. de Vere Stacpoole, and *The Coming of Amos* by William J. Locke.

Abstracts from Current Literature

SYPHILIS

Abortive Treatment of Syphilis.—R. Pollard (*Wiener klinische Wochenschrift,* February 14, 1924) states that the only effective abortive treatment of syphilis is salvarsan, best combined with mercury, or in the form of silver salvarsan. The author's statistics do not indicate whether in the combined treatment the intramuscular administration of mercury or the socalled mixed injection is preferable. If the treatment is begun after the lapse of three weeks after the infection, a cure can be expected in only ninety per cent. of the cases. After four weeks a cure can be expected only in seventy-five to eighty per cent. of the cases. After five weeks only fifty to sixty per cent. of cases are possible, and after six weeks only about forty per cent. of the cases are cured. A positive Wassermann reaction at the beginning of the treatment does not necessarily prevent a cure and besides the prognosis is not markedly made worse if the disease has lasted only a short time. Reversely, relatively frequent failures occur in beginning seronegative cases. A persistently positive Wassermann reaction is not always a sign of incurability, especially if no clinical signs or symptoms were ever present. Such an occurrence may be explained by the fact that in certain individuals having marked powers of resistance the formation of immune bodies persists longer than the duration of the disease, sometimes throughout life. It has been shown that positive cases have become negative after eight to nine years. The author has never observed any unfavorable effect upon the course of the disease as a result of abortive treatment, but only the future can show whether late recurrences will appear after years. The author believes that he can already say that such an occurrence will be rare.

Experimental Observations on the Cure of Syphilis in the Rabbit with Arsphenamine.—Alan M. Chesney and Jarold E. Kemp (*Journal of Experimental Medicine,* April, 1924) report experiments which show that the administration of arsphenamine intravenously to rabbits in doses of ten mg. to the kilo to the extent of six doses spaced at intervals of one week is sufficient to eliminate an existing syphilitic infection, as judged by lymph node transfer performed thirty-two to thirty-eight days after cessation of treatment, even if the infection has been present for a period of 127 days when treatment is begun. The syphilitic rabbits that have been treated in this way and whose popliteal nodes thirty-two to thirty-eight days after treatment have been shown to be incapable of transmitting the infection to normal animals are, as far as can be judged by the absence of a local lesion, refractory to a second inoculation of active virus of the same strain, if the inoculation be made intradermally at the base of the ear, and carried out 209 days after the first inoculation. This is also true of untreated syphilitic rabbits. The authors believe that the demonstration of presence or absence of a lymph node infection affords a better criterion for the evaluation of an antisyphilitic agent than does the method of reinoculation. They also point out that failure to reinoculate treated syphilitic rabbits does not necessarily indicate the presence of infection in the latter, but may, on the other hand, indicate the existence of an acquired immunity.

Uterine Syphilis.—J. T. Windell (*American Journal of Surgery,* March, 1924) reports on two cases and reviews the literature with the following comments:

The spirocheta pallida may avidly attack every organ, tissue or structure embraced within the human economy, and the uterus and its adnexa are not exempt. Until comparatively recent years, however, the strange impression prevailed that the endometrium was immune to spirochetal invasion; that such impression was erroneous there is now abundant evidence.

The treatment of uterine syphilis has already been sufficiently discussed. It differs in no essential respect from the therapy of luetic infection involving other organs and tissues of the body. Rapid subsidence of symptoms is the rule and the patients are at least clinically cured.

From a clinical viewpoint the question of socalled syphilitic hemorrhages is perhaps of the greatest interest. The practice of attributing symptoms which disappear under antisyphilitic treatment, in patients exhibiting a positive Wassermann reaction, to a syphilitic origin is at least open to scientific doubt. Probably the uterine hemorrhage in many cases is properly attributed to syphilis, but, on the other hand, with a disease so common as syphilis, and considering the numerous and often obscure nonsyphilitic lesions that may cause hemorrhage, it is but reasonable to assume that combination of these may occur and hemorrhage in some instances may be the result of disease totally unrelated to luetic infection.

The clinical diagnosis of luetic uterine involvement is seldom made in the early stages of the disease. In the majority of instances no history of primary or early secondary lesions can be obtained and when observed the patient may exhibit no symptoms to suggest that the internal genital organs be thoroughly investigated. Local examination in consequence may be delayed until supervention of profuse vaginal discharge, menorrhagia or metrorrhagia. The Wassermann reaction is then positive and spirocheta pallida can usually be demonstrated in the infected tissues and their excretions. However, the diagnosis of uterine lues seems warranted even where no spirochetes are demonstrable when the Wassermann reaction is positive and clinical signs exist. The diagnosis is further confirmed by the therapeutic test, i. e., the subsidence of clinical manifestations after antisyphilitic treatment. Routine Wassermann tests on all women with gynecological affections would probably demonstrate the presence of luetic infection in a greater number of instances than hitherto suspected. It must be remembered that syphilis is not infrequently coexistent with other diseases.

Colloidal Benzoin Reaction in the Cerebrospinal Fluid.—J. A. Braxton Hicks and John Pearce (*British Medical Journal,* February 16, 1924), compared the colloidal benzoin reaction under routine hospital conditions with the other well known tests carried out simultaneously on the same specimens. They found the colloidal benzoin reaction a simple test and very nearly as sensitive to syphilis of the central nervous system as the Wassermann reaction. It is not quite as sensitive as the Wassermann reaction. The authors cannot agree with those who contend that there is a characteristic luetic curve as contrasted with a paretic curve. It is true that some cases of tabes show less tendency to precipitate in tubes 9, 10 and 11, but so did one or two cases of undoubted general paralysis of the insane. A positive result (that is, precipitates in tubes 1 to 6 at least) is not obtained with any disease other than syphilis of the central nervous system so far as we have been able to ascertain. Definite changes (other than a complete positive, and in the absence of blood) indicate apparently some definite pathological change in the cerebrospinal fluid; but all pathological fluids do not necessarily show any colloidal benzoin reaction.

Wassermann and Kahn Reactions.—F. B. Johnson and W. L. A. Wellbrock (*Southern Medicine and Surgery,* April, 1924) record the following results of a series of parallel tests:

1. In a series of 1,935 parallel Wassermann and Kahn tests an agreement of 91.6 per cent was found.

4. A positive Wassermann test by the Kolmer method is perform than the Wassermann, but cannot replace it, because the latter shows a higher percentage of positive results in known cases of syphilis.

3. In syphilis the Kahn test gives a certain number of positive results with the Wassermann negative, and likewise the Wassermann shows a certain number of positives with Kahn negative.

4. A positive Wassermann test by the Kolmer method is diagnostic of syphilis.

5. A positive Kahn test, with few exceptions, means that syphilis is present.

6. In the reading of the results of the Kahn test, considerable difficulty is encountered in those that are not strongly positive. Experience and careful technic are important factors.

7. In treated cases of syphilis the Wassermann tests appear to be more sensitive than the Kahn.

8. With spinal fluid a certain number of positive results can be obtained by the Kahn method, but these are only about one half as many as can be obtained by the Wassermann test in syphilis.

9. It is therefore considered advisable that the Kahn test be used in conjunction with the Wassermann in all serological examinations made for the diagnosis of syphilis; because, on account of its close agreement, it acts as a check on the Wassermann, and also gives a certain number of positive results when the Wassermann is negative.

A Flocculation Test for Syphilis.—C. B. McGlumphy (*Journal of Laboratory and Clinical Medicine,* May, 1924) has prepared an antigen from human heart muscle, and is convinced that flocculation occurs when this is mixed with luetic serum. Of the four hundred sera tested, the Wassermann reaction agreed in 98.25 per cent. Negative serum shows no flocculation when mixed with such an alcoholic extract. Glycerine in amounts of 0.05 c. c. added to the mixture of alcoholic extract and serum increases the size of the floccules in a positive test, thus making the reading easier.

Atypical Distribution of Varicella Lesions Dependent Upon a Coexistent Syphilitic Infection.—W. S. Tillett and T. M. Rivers (*Bulletin of the Johns Hopkins Hospital,* May, 1924) report a case of varicella in which the unusual distribution of the lesions was dependent upon the irritation of the skin by a coexistent disease—hereditary syphilis. The eruption was most marked over the face, scalp, and extremities, instead of over the trunk. The case reported is an example of the influence which one disease may have on the distribution of the lesions of another occurring simultaneously in the same patient.

SURGERY

Surgery of the Pituitary Gland.—P. Sargent (*British Journal of Surgery,* January, 1924), summarizes his views as follows:

Operations for pituitary tumor are only justified as a means of relieving headache or averting blindness. Tumors are rarely, if ever, capable of complete removal. The choice of operative approach lies between the transphenoidal method of Cushing, the frontal route of Frazier, and the temporal route of Horsley. The first named is comparatively easy and attended by a low mortality rate, but its field of usefulness is limited to one type of pituitary tumor in which the sella turcica is considerably enlarged; the second gives better access, and can be used for all varieties of lesion in or near the pituitary gland; the third is useful for cases in which the general intracranial pressure is high.

Fracture of the Femur.—R. H. Russell (*British Journal of Surgery,* January, 1924), offers the following point of view on fractures.

1. In a limb previously normal that is rendered perfectly comfortable in a natural position, muscular action is never the cause of displacement of fragments.

2. The causes of malposition of fragments are three in number, viz., unnatural position and discomfort; action of gravity, and splints.

Unnatural position and discomfort: The most universal and the most unfortunate error that has hampered the treatment of fractures is the belief that the limb must be placed in a certain position to meet the supposed requirements of a short proximal fragment that is being uncontrollably displaced by a certain muscle. The author instanced the case of the iliopsoas muscle in fracture just below the lesser trochanter; and an equally good example taken from the upper extremity will be the visible displacement of one or other fragment of a broken humerus by the deltoid muscle. It would at first sight appear almost incontestably right in principle that the limb should be brought into alignment with the proximal fragment that is being pulled out of place in this way. This is not the case, however, for the visible displacement, obviously caused by muscular action, is only a transient phenomenon, and will disappear as soon as the limb is put into a comfortable position and the surgeon's back is turned. So that when, with considerable pains and ingenuity, we have fixed the limb in an unnatural and uncomfortable position in deference to the proximal fragment, we shall find that the proximal fragment ten minutes later will have changed its position altogether, that it and its muscles have assumed the position to which they are accustomed, and that the position we have assigned to the limb is altogether wrong. We ought to have disregarded the proximal fragment altogether, and placed the limb in a position that we know to be natural and comfortable, with the assurance that the position which is natural and comfortable for the entire limb will be equally so for the proximal fragment in common with the rest, and that such position will be that which it will assume.

The action of gravity: This is the sole inescapable cause of angulation in the case of the femur, and is met and counteracted with the utmost ease, as has been already described. It is the great advantage of our simple methods that the seat of fracture is always exposed to inspection and easy handling.

Splints: The means of avoiding this source of difficulty are obvious. The Thomas splint, invaluable for many purposes, we never employ in the treatment of fracture of the femur, whether simple or compound.

To recapitulate: In fracture of the femur, given a method of pulling out the thigh muscles to their normal length by an appliance that is perfectly comfortable, nothing will then remain to be done except to counteract the effect of gravity at the seat of fracture.

Treatment of Ununited Fractures.—J. M. Salmon (*International Journal of Medicine and Surgery,* January, 1924), details the following treatment, operative, for ununited fractures.

Before deciding upon any operative procedure, it is necessary to wait until all latent infection has subsided. During the waiting period, the limb should be massaged and the circulation improved by heat, congestion and bandaging. Joints should be mobilized and muscular atrophy prevented by passive motion. Extensive and adherent scars should be removed and skin grafting employed. "The longer the period of delay, and the greater the trouble taken preparatory to reconstruction of bone, the greater the chance of success" (Hey Groves). The operative technic must be aseptic. In no other department of surgery is this more important. Hemostasis must be complete and the post-operative immobilization efficient.

In operating upon ununited fractures, two cardinal principles must be borne in mind: First, the osteoblasts necessary for new bone formation are contained in the dense bone; therefore, there must be contact of the osteogenetic layers. Second, the blood supply to these osteoblasts must be definite and sufficient without interference by scar tissue.

The type of operation to be employed will depend upon the conditions presenting. Step cutting is useful where the resulting shortening is not a serious disadvantage, as in the humerus and forearm. Intramedullary pegs are satisfactory where there is a considerable gap and where it is difficult to maintain alignment. Such pegs should be approximately three times the length of the gap and should be of living bone with its periosteum and subjacent dense bone. Inlay grafts are most generally applicable and give excellent results. It is essential that the ends of the graft be maintained in firm contact with healthy, well nourished bone.

If plates are used, they should be considered merely as internal splints, and, as already stated, there must be firm apposition of healthy bone. As a general rule, plates should be avoided in the treatment of nonunion.

Internal Splinting of the Spine.—P. H. Magnuson (*Surgery, Gynecology and Obstetrics,* January, 1924) reaches the following conclusions from his study of twelve cases.

1. A heavy bone graft is much preferable to a light one because it may be fastened to the spinous processes in such a way that it will give immediate immobilization, immediate relief from pain, and do away with the necessity of uncomfortable body casts, and allow the patient to move freely in bed and to assume the upright position within three weeks of the time of the operation.

2. The ivory screws inserted through a heavy bone graft into the spinous processes make a firmer and stronger fixation immediately than any other device. Heavy, braided silk, where it is not possible to use ivory screws makes a firmer and more constant fixation than does kangaroo tendon or catgut, and does not cause any more irritation of the tissues than do these other materials.

3. This type of fixation of the spine should be done wherever chronic disabling pain and increasing deformity exists as a result of the following conditions: a, tubercu-

losis of the spine; b, tuberculosis caries of the bodies of the vertebræ; c, fracture of the spine—compression of the bodies, fracture of the articular processes; d, forward slipping or relaxation of the fifth lumbar vertebræ; e, chronic strain with relaxation of the ligaments where there is malformation at the lumbosacral articulation with disabling backache.

Modified Fusion Operation.—P. Lewin (*Journal of Bone and Joint Surgery,* January, 1924) proposes a new operative technic for the spine. Its object is to produce more rapid ankylosis. The classical fusion operation is used with the technic of Hibbs. One or two osteoperiosteal grafts, obtained from the tibia by the technic of Delagénière, are placed in a bed of bone that has been denuded of its osteoperiosteal layers. The purpose of the graft is not to produce a splint but to furnish all the elements necessary in the production of new bone and thereby effect a more solid early ankylosis, which is the desired result. The method is applicable to those conditions where solidification is indicated, as tuberculosis fracture, and scoliosis, but especially in tuberculosis. The writer believes that the osteoperiosteal graft, first recommended by Ollier and accentuated and established firmly by Delagénière, is the most efficient bone producer at the present time. If we could produce a hypertrophic arthritis limited to the affected area it would be ideal. This method is the nearest approach to it.

Etiology and Treatment of Claw Foot.—G. P. Mills (*Journal of Bone and Joint Surgery,* January, 1924), presents the following summary of his study. Claw foot is an acquired deformity, occuring most frequently in adolescents and rather more commonly in males than in females. Shortening of the tendo Achillis is not an essential part of the deformity but is present as a complication in about one quarter of the cases. The deformity is such as would be theoretically expected from paralysis of the external plantar nerve. The evidence that temporary paralysis or paresis of this nerve is the cause of the deformity, while not complete, is certainly suggestive. In early cases simple treatment by splints and boots will often avoid the necessity for operation. For moderate cases transplantation of the extensor proprius hallucis is a satisfactory operation. In advanced cases, when portions of the inner four metatarsals are removed, it is advisable to divide the fifth metatarsal at the same time.

Separation of Quadriceps from Patella.—I. Zadek (*Journal of Bone and Joint Surgery,* January 1924), reports as follows on two cases, pointing out the differences between separation and rupture of the quadriceps tendon.

1. History suggestive of underlying weakness. The first patient sustained several injuries to the knee, each somewhat more disabling than the preceding, until the last, which was fairly complete. The second patient had sustained a similar injury to the left knee eleven years previously.
2. Local subjective pain at the site of injury is slight, and local pressure causes a very moderate amount of discomfort.
3. There is a depression just above the superior border of the patella into which one finger will fit transversely.
4. There is complete loss of power of extension of the leg.
5. There is no enlargement of the lower end of the proximal segment, but just a perceptible quiver on attempted contraction of the quadriceps, thus differing from the reported cases of ruptured quadriceps.
6. There is a strikingly slight amount of hemorrhage.
7. At operation the patella is smooth and covered with a periosteumlike structure (the patella, being a sesamoid bone, has no periosteum). Only part of the fibres of the vastus internus are intact. The joint is found open, exposing the intercondylar space of the femur.
8. The end result is complete restoration of function (incomplete in the second patient, due to an old arthritis) after operative suture.

Crushing Fractures of the Os Calcis.—W. L. Sneed (*Journal of Bone and Joint Surgery,* January, 1924), summarizes his findings as follows.

In the series of cases presented there was one point in common—tenderness. In three cases there was also pain under the heel and tenderness. It is my opinion that when an os calcis is severely crushed by a fall upon the heel, and the astragalus is driven down into it, widening the heel and lowering the external malleolus so that it impinges upon the fractured os calcis, changing fibula from a stay of the ankle joint into a weight bearing bone, for which nature never intended it, pain is produced. It was the persistent pain and tenderness in the first case in this series that first started the author upon this investigation. He wishes to emphasize the necessity of allowing for drainage when operating in these cases, as there is considerable oozing of blood. One other point he wished to stress is that it is difficult to show by radiogram the tunnel after it is made in the os calcis. He insisted upon the patient bearing weight upon his foot at an early date. This was a necessary extra precaution so that dense fibrous tissue might not form and impinge upon the external malleolus.

Operative Treatment of Congenital Dislocation.—F. P. Dickson (*Journal of Bone and Joint Surgery,* April, 1924), presents five cases of which four, or eighty per cent., proved quite satisfactory. He concludes therefore: An operation of election should never be performed unless very definite indications exist and there is a reasonable chance of securing improvement in the condition for which it is done. Any operation on an untreated or on an unsuccessfully treated congenital dislocation of the hip in an adult is an operation of election. It follows then that the indications for operative intervention in such cases must be clean cut and definite. In the author's cases he considered that only one indication existed, and this was disability of a degree sufficient to interfere with the ability of the individual to lead a normal life.

While he appreciates that five is perhaps a small number of cases on which to base conclusions, still the results have been satisfactory enough to seem worth while reporting. Basing our conclusions on these five cases he feels that an operative procedure is useful and worthy of consideration in cases of congenital dislocation of the hip in adults where there is sufficient instability to interfere with the individual's ability to lead a normal life.

Sequelæ After Operation for Internal Semilunar Cartilage.—N. Dunn (*Journal of Bone and Joint Surgery,* April, 1924), reports on a rare case, which, together with his experiences in seven additional cases where incomplete recovery after removal of the internal semilunar cartilage appeared to be due to involvement of the saphenous nerve in the scar, leads him to conclude as follows: 1. That a neuroma of the patellar branch of internal saphenous nerve may explain certain cases of incomplete recovery after removal of the internal semilunar cartilage. 2. That simple excision of the scar may not be sufficient to cure the condition. 3. That excision of the scar and evulsion of the nerve is the most satisfactory treatment. The risk of these sequelæ may be obviated by retraction of the nerve or evulsion of the proximal portion of the nerve at the time of operation.

Scoliosis Fusion Operation.—R. A. Hibbs (*Journal of Bone and Joint Surgery,* January, 1924) from a study of fourteen cases, says that these cases give evidence that we have in fusion a means of preventing the progress of deformity in scoliosis in cases in which it is caused by muscle imbalance; that the operation should be done before gross deformity has developed, as it is easier to prevent than to correct deformity; that after fusion the upright posture is maintained with greater ease and trunk movement exercised with less fatigue.

Arthroplasty.—P. Santy (*Surgery, Gynecology and Obstetrics,* September, 1923) offers the following conclusions from his study. Arthroplasty enlarges considerably the field of operation for ankylosis. In the hip and knee arthroplasty opens up almost a virgin field in joint surgery. Resection for ankylosis becomes a secondary method to be used only after failures by arthroplasty or in those cases in which the condition of the bones of the joint, or more rarely the condition of the soft parts, makes mobilization a hopeless procedure.

Mobilization of Ankylosed Joints.—W. R. MacAusland (*Surgery, Gynecology and Obstetrics,* September, 1923) presents a study of arthroplasty, historical, experimental and clinical, with numerous recent cases. He stresses the following points: That excision of a joint does not constitute an arthroplasty; that highly developed technical skill is absolutely necessary; that judgment in the selection of cases is very difficult.

DIABETES

Xanthoma Diabeticorum.—Ralph H. Major (*Bulletin of the Johns Hopkins Hospital,* January, 1924) reviews the literature of the condition, and reports three cases in which studies were made on the blood cholesterol. Two of the patients wtre treated with insulin. In the first case, the blood cholestrod was 432 mg. to 100 c.c.; in the second it was 632 mg. to 100 c.c. Insulin therapy caused a disappearance of the lipemia in four days, and a prompt fall in the blood cholesterol to a normal value. A like effect was observed in the third patient after insulin, whose initial blood cholesterol was 533 mg. per 100 c.c. The clearing up of xanthoma diabeticorum depends partly upon a disappearance of the lipemia and lipoidemia, and partly upon the degree of blood supply which permits absorption of the substances in the xanthomatous lesions.

Insulin Treatment of Diabetes Mellitus.—W. Falta, F. Depisch, and F. Högler (*Wiener Archiv. für Innere Medizin,* April 1, 1924) show that it is possible to increase the tolerance to food by combined dietetic and insulin treatment to a greater extent than with the purely dietetic treatment alone. With simultaneous insulin therapy the tolerance may be raised with the same success on a mixed diet with low sugar values as with the strictest dietotherapy of Petren, which causes the patient great privations and even not harmless digestive disturbances. The authors were also able to show that with the combined treatment it is possible to maintain the increased tolerance to food even in those cases in which this was no longer possible with dietetic treatment alone. In regard to the relief from acidosis, the insulin treatment is a great advance in so far as the acidosis may be avoided even in those cases in which this would not be possible with a purely dietetic treatment, and besides, this could be accomplished with considerably less privations on the part of the patient. In the use of insulin the most important consideration should be the reduction of the fasting blood sugar content to normal or below normal. The nature of the diet must depend entirely upon the individual case.

Insulin Treatment Without Blood Sugar Estimations.—Arthur Innes (*British Medical Journal,* January 12, 1924), reports that two days' fasting, and then a "ladder diet" until the patient's urine begins to show sugar, gives the starting point for the first insulin injection, which the author intends to give in the future twice a day, starting with twenty minims in the day. Food must be ready for the patient as soon as he receives his injection, and in no circumstances can longer than fifteen minutes be allowed to elapse. The patient must always have sugar and water at his bedside, and be advised to take a small amount should symptoms of faintness, depression, air hunger, etc., appear. He must be educated to the testing of his urine for sugar and keep a record of every specimen voided for the first two weeks and morning and evening thereafter. Do not start if there is any fear that the treatment cannot be kept up, and it can never be forgotten that at present the cost of the insulin is very great. Do not attempt to get a constantly sugar free urine. A trace of sugar in the morning specimen is a safeguard giving a feeling of assurance that no harm can result from the treatment. It cannot be forgotten at any time that the treatment of diabetes is still a matter of careful dieting, and that insulin is only our greatest and most valuable aid.

Diet During Insulin Treatment of Diabetes Mellitus.—K. S. Hetzel (*British Medical Journal,* February 9, 1924) states that insulin has not removed the need for an accurate control of food in diabetes, but it has rather emphasized that need. He has advanced the following general guiding principles: 1. The total dietary of an adult diabetic for each day should rarely exceed 2,000 calories. 2. The protein allowed each day may be at the rate of 0.5 gram or slightly more for each pound of the patient's body weight. It must not be forgotten that protein contains over half its weight of substance which can yield sugar. The carbohydrates may reach a total of thirty to sixty grams, and the fats should not exceed the sum of twice the carbohydrates together with half the protein, lest acetones appear in the urine, and diabetic coma develop as the result of faulty metabolism of the excess fats. 3. Glycosuria must always be fully controlled, or the patient cannot improve; and therefore carbohydrates must be strictly limited by the glycosuria. 4. If the supply of insulin fails temporarily the diet must be cut down, especially in respect of the fats, and the patient should rest. 5. Intercurrent infections or surgical operations compel a temporary increase of the insulin needed to abolish glycosuria on any particular diet. 6. Diabetic coma must be treated promptly and freely with insulin, for recovery is impossible if the patient has been in coma for more than twelve hours. 7. Every patient on insulin must be instructed in the symptoms of hypoglycemic collapse, and know how to check them by taking sugar. Any patient of ordinary intelligence can be taught to give his own injections of insulin.

A Case of Diabetes Refractory to Insulin Relieved by Antiluetic Treatment.—A case related by Paul H. Charlton (*Endocrinology,* March, 1924), is that of a colored man with pulmonary tuberculosis and diabetes mellitus, whose blood sugar failed to respond to dietary regulation and to insulin, although the latter caused his glycosuria to disappear. Antiluetic treatment proved effective respecting both.

Effect of Insulin upon the Complement Derived from Insulinized Guineapigs for the Wassermann Reaction.—Otto S. Kretschmer (*Journal of Laboratory and Clinical Medicine,* April, 1924), did the experimental work reported to determine whether the hypoglycemia produced by the injection of insulin, or some other change produced in the blood by insulin, might alter the action of complement derived from the guineapig in performing the Wassermann reaction. The results of this study demonstrate that the pooled serum of guineapigs, treated with insulin over a short period of time, in which acute hypoglycemic symptoms have thus been created, shows no appreciable change in its complementary titre in comparison with guineapigs not so treated, and retains this property for fully thirty days.

Sixteen Months' Experience with Insulin.—Byron D. Bowen (*Buffalo General Hospital Bulletin,* January, 1924), reports upon 107 cases of diabetes selected for insulin treatment out of a group of 173 cases observed for sixteen months. Insulin appears to bring about much more satisfactory results in young patients without complicating diseases. Even young people with extreme diabetes have improved miraculously. Death has at least been averted in nineteen patients, thirteen of them being below the age of forty. What is equally encouraging is the restoration of thirty-three patients to useful and productive lives. By means of insulin, the management of coma and acidosis cases has been made more satisfactory, and the results have been materially improved. Even better, however, were the results in the precoma group, although the CO_2 capacity of the plasma was not essentially different than in the cases of deep coma. Here also complications, especially acute infections and thyrotoxicosis, influence materially the outcome of severe acidosis cases. While the eventual outcome of diabetic patients who are absolutely dependent upon insulin for their nutrition is uncertain, the diabetes should be held in abeyance when feasible, in order to prevent if possible, the loss of what native tolerance remains, and to defer such complications as are likely to arise in prolonged diabetes. To accomplish this, especially in very severe cases, if they are to be put on a full maintenance diet, the most meticulous care must be exercised, requiring full cooperation between the patient, the physician, the dietitian, and the laboratory.

Studies of the Effect of Exercise in Diabetes. I.—Harold E. Himwich, Robert O. Loebel, and David P. Barr (*Journal of Biological Chemistry,* March, 1924) state that qualitatively the reaction of diabetics to exercise seems to be similar to the normal. There is in both a reduction in CO_2 capacity, CO_2 tension, and blood alkalinity. Quantitatively it appears that for an equivalent amount of exercise the change both in CO_2 capacity and pH is greater in the diabetic. The reduction in CO_2 capacity can be accounted for quantitatively by the increase in lactic acid in the diabetics studied.

Glycolysis in Bloods of Normal Subjects and of Diabetic Patients.—Edward Tolstoi (*Journal of Biological Chemistry,* May, 1924) studied the glycolytic power of eight normal subjects and of eleven diabetics, in some instances both at room temperature and at 37° C., using aseptic precautions. No diminution in the glycolytic power of diabetic bloods was observed when compared with that of normals at 37° C. At room temperature, the rate of glycolysis of diabetic and normal bloods was definitely slower. The various results reported by different workers may be explained by the fact that no uniform temperature was employed.

DEFENDANT'S NEGLIGENCE CAUSING INJURY BY MALPRACTICE MUST BE PROVED

In an action for malpractice in treating plaintiff for an injury resulting from being run down by a motor cycle, it appeared that plaintiff was taken to defendant's office; that defendant examined him and found an open wound in his right leg, which he dressed, that he attended him for several days, when he was dismissed from the case; and that another doctor attended plaintiff for over three months, when he was taken to a hospital, where several weeks later his leg was amputated six inches below the hip. There was evidence tending to show that the cut or wound had become septic; and that pus had formed above the wound and discharged through it. A verdict was rendered for plaintiff and defendant brought exceptions.

An exception to an instruction to the jury to consider the defendant's failure to discover a fracture of the fibula was sustained, there being undisputed medical testimony showing that the failure of the defendant to discover and treat this fracture did not result in any septic condition, nor any evidence that it was a cause or a contributing cause of the plaintiff's condition resulting in the amputation of his leg, nor was this claimed by the plaintiff.

It was also held that the trial court should have granted defendant's request for an instruction that the fact that the plaintiff suffered sepsis and amputation of his leg did not raise a presumption of want of proper care and skill or of negligence on defendant's part in his treatment of the plaintiff. King v. Belmore, Massachusetts Supreme Judicial Court, 142 N. E., 911.

PHYSICIAN'S LIABILITY UNDER OKLAHOMA'S ANTINARCOTIC LAW

In a prosecution under the Oklahoma Statute, section 8887, Comp. Stat., 1921, charging the crime of transporting narcotic drugs from a place unknown to Oklahoma City there was testimony as to the sale by defendant, a physician, of a quantity of narcotic drugs to an addict. On appeal from a judgment of conviction, the defense was that under the provisions of this statute a physician is authorized to transport narcotics. The Oklahoma Court of Criminal Appeals held, Stout v. State, 224 Pac., 375, that the statute was designed to prohibit the unauthorized sale, introduction and transportation of narcotic drugs; and that it applies to physicians as well as to others, excepting only in cases where the use of narcotic drugs is necessary in the treatment of disease, and then only in such quantities and in such manner as is designated in the statute. The fact that the accused is a physician will not make him immune from punishment under the penal provisions of the statute in cases where the penal provisions of the statute in cases where he knowingly participated in the unauthorized traffic in narcotics. And where such a penal statute expressly provides that certain exceptions to or exemptions from its operation shall be matters of defense, such exceptions need not be negatived in the information.

Letters to the Editor.

MATERNAL WELFARE

Kansas City, Mo., *August 30, 1924.*

To the Editor:

A nation wide movement for improved conditions in maternal welfare is being inaugurated through the combined efforts of a joint committee representing the American Gynecological Society, the American Child Health Association, and the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons. An appeal is being made to the secretaries of the State Medical Associations to enlist the cooperation of their members and also of the constituent County Medical Societies to stress the subject of obstetrics in the programs of their meetings and try to have more papers and discussions on the topics vital to this most essential branch of our work.

The reason for the propaganda is that recent statistics are published showing a deplorably high mortality in maternity work in our country. A Washington report gives the United States the unenviable position of third from the highest death rate in both sepsis and eclampsia among the seventeen civilized nations of the world. These two accidents are almost absolutely preventable. Among the reports from sections where prenatal care is taught and where aseptic care observed in labor the mortality is reduced one third to one half the average in the same region.

So many other features while not so tragic demand reform in obstetrics that the committee hopes within five years that not only the mortality of mothers and children may be reduced, just as the profession has cut down the death rate in typhoid fever, tuberculosis and diphtheria in recent decades, but also that obstetrics may be again placed on the plane with internal medicine and surgery, a dignity which it formerly occupied in the colleges and in the profession, as one of the three great branches of the healing art. This is a work of education, and it demands the cooperation of teachers and specialists in obstetrics, general practitioners, nurses, and the general public, to accomplish so ambitious a program.

The Annual Report to the American Association of Obstetricians, Gynecologists, and Abdominal Surgeons details some of the conditions found and shows the more hopeful outlook for the future.

Trustworthy!

The extent to which innumerable practitioners of medicine are today employing

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

whenever a dependable reconstructive tonic is called for, tells in no uncertain way of its therapeutic utility and gratifying efficiency.

During the thirty-five years this reliable tonic has been at the service of the profession, the quality of its ingredients and the unvarying character of the composite product have been consistently and faithfully maintained.

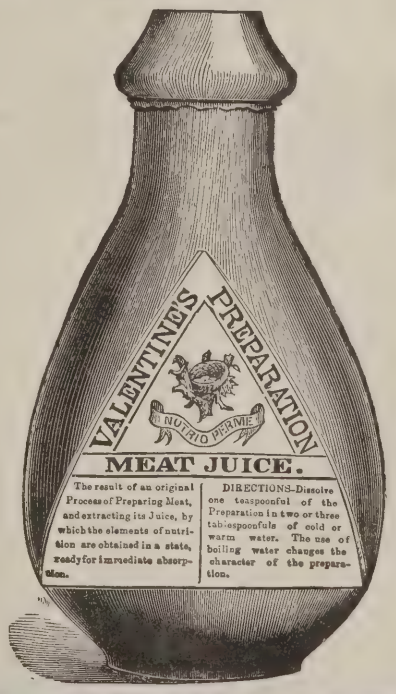
Thus it is easy to understand why the host of medical men who have learned how reliable it is in its character and results, not only take pains to order the original Gray's Glycerine Tonic Comp. (P. F. Co.), but also to see that their patients get no other!

Such care is well worth while, for it often measures the difference between success and failure.

The Purdue Frederick Co., 135 Christopher St., New York

Valentine's Meat-Juice

In **Diarrhoea, Dysentery** and **Cholera Infantum,** in the **Wasting** and **Febrile Diseases** of **Children,** and in the treatment of **Weak Babies,** the **Ease** of **Assimilation** and **Power** of **Valentine's Meat-Juice** to **Restore** and **Strengthen** has been demonstrated in Hospitals for Children.



VALENTINE'S PREPARATION
NUTRIO PRAYME
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Diseases of Children.

W. T. Watt, M. D., *Director Imperial Medical College, Tientsin, China:* "In cases of Infantile Diarrhœa, which weakens and debilitates a child rapidly, I have found VALENTINE'S MEAT-JUICE a great stimulant and quick restorative of vitality. Three years ago when an epidemic broke out in Tientsin, I ordered my staff to try your MEAT-JUICE, which justified all expectations, having been satisfactory to patients and physicians alike."

Dr. Calatraveno, *Late Physician of the Children's Hospital, Madrid, Spain:* "I have employed VALENTINE'S MEAT-JUICE most successfully in cases of convalescence from infectious diseases, and it is especially beneficial for children suffering from urinary weakness caused by extreme debility, as in every case it acted remarkably in restoring their strength with notable rapidity."

Physicians are invited to send for brochures containing clinical reports

For sale by American and European Chemists and Druggists.

S 112 **Richmond, Virginia, U. S. A.**

Miscellany.

The First Orthopedic Clinic in Holland.—It is remarkable that orthopedics have hitherto received so little attention from the medical profession in Holland, but this condition is likely now to be remedied by the opening, at Leyden, of a new orthopedic clinic—the first in the country, says an editorial writer in the *Lancet,* August 23, 1924. For more than ten years a number of infirmary buildings have been under construction in Leyden, supplied with laboratories, clinics, and dispensaries for every branch of medicine at a total cost of some £1,250,000. One of the buildings, which was originally designed for a fever hospital, has been allocated to the Society for the Welfare of the Crippled and Disabled. This hospital has accommodation for forty beds, twenty of which will be paid for by the Government and will be used for teaching purposes. Dr. Murk Jansen, who is now lecturer in orthopedic surgery at the university, has been appointed director. Many difficulties had to be overcome before this project could be carried out. The opposition to the establishment of the clinic on the part of some surgeons is noteworthy, the *Lancet's* correspondent writes, as giving an idea of the old fashioned professional outlook in Holland in certain directions. The surgeons there have continually opposed the separation of any branch of medicine from surgery, and for this reason it took a long time before otorhinolaryngology, dermatology, and urology became separate specialties. For the same reason, too, there are in Holland no surgeons who specialize in surgery of the abdomen or brain. It must be remembered that for many years in all the British medical centres specialism was looked at with considerable suspicion, one fact being insisted upon and another fact suppressed. It was continually pointed out that there could be no sound specialism that was not founded on general medicine, but it was a long time before it was allowed that progress along special lines would be most surely arrived at by special work. The first is true, but the second is no less true. The establishment of the new clinic, under an orthopedic surgeon so well known as Dr. Jansen, should do a great deal to further in Holland the development of this branch of medical science.

Sutures.—The problem of suture materials is one which has taxed surgeons from very early times, says a writer in the *Lancet,* August 23, 1924. Since Ambroise Paré startled his scientific world by daring to ligate a bloodvessel, surgeons have continuously sought a material which would do what they require without introducing some element of secondary difficulty. In a septic wound to introduce a foreign body is to invite trouble, and even where the most scrupulous asepsis can be maintained it has always been evident that to leave unabsorbable material in a wound is a defect, however necessary, in surgical technique. With the introduction of catgut it was thought that the problem had at last been solved, but it was soon found that the difficulty of controlling the rate of absorption was considerable. However carefully catgut may be prepared, individual variations in absorptive power are enormous, and the "forty day" label in which the surgeon confides is a very rough index, considering the variation in rapidity of absorption in the muscles, the peritoneum, or the stomach, in the child and in the man, quite apart from anomalies in the catgut itself. Silk will certainly remain in the tissues, but surgeons have found to their cost that it may frequently gather to its folds seven other devils worse than itself in the shape of chance bacteria, and the end of that patient may be worse than the first. An ingenious compromise was suggested recently by Mr. D. McIntyre, whereby a fine filament of silk is embedded in a strand of catgut. The catgut is absorbed, and the fine silk appears to give rise to no trouble. The larger suture is easier to handle than fine silk, and has not the same tendency to cut through the tissues at operation. For, apart from the duration of suture materials, we have to consider the endurance of the material sutured, and it is to be feared that we often forget how slight this is. Generally speaking, there is no known means by which two portions of soft living tissue can be kept together artificially for more than ten days. If union has not occurred within that time, the sutures cut through and the tissues fall apart. Indeed, in many cases five or six days is the longest period for which reliance can be placed upon sutures, not because they are absorbed, but because the material sutured disappears. It is said that certain materials such as kangaroo tendon and silk impregnated with mercury are not absorbed, but are invaded by living tissue cells and practically become embodied in the tissues. Were this the invariable result of their introduction the surgeon would have attained his ideal, but unfortunately it is not always the case. It is well, however, that we should recognize that the only permanent suture, if it is ever discovered, will be one that is gradually embodied in the living tissues, and that unless this condition is satisfied, no suture, whatever its durability, can hold soft tissues together for more than a few days.

Botanical Research in China.—Professor John M. Coulter, head of the department of botany of the University of Chicago, lectured during the session of the British Association for the Advancement of Science on the progress of botanical study and research in China, as he saw it during his recent five months' visit. The most important botanical work, said Dr. Coulter, is being conducted at the National Southeastern University of Nanking and at Nanking University. It is notable in being concerned chiefly with practical problems in developing the natural resources of the country. The untouched possibilities of China are most impressive. The College of Agriculture of Southeastern University at present has one large experiment station and nine substations, all well equipped.

The principal botanical enterprises under way in China are, first, a complete collection of the native plants of Central China, not only for purposes of classification but also as sources of valuable raw materials and drugs; second, reforestation, for most of China is completely denuded of trees; third, improvement of vegetables, notably the soy bean; fourth, improvement of cotton; fifth, studies on bamboo; sixth, problems of plant disease.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Disease Prevention.—Major General Sir David Bruce, K.C.B., F.R.S., chairman of the governing body of the Lister Institute of Preventive Medicine, in his inaugural address as president of the British Association for the Advancement of Science, outlined the new strategy of medical science in its efforts to prevent the disease and disability which cause a direct loss annually amounting to $750,000,000 in England and $30,000,000,000 in the United States. When the British Association first met in Canada forty years ago, said the speaker, "we were still in the gloom and shadow of the dark ages. Now we have come into the light. Man has come into his heritage and seems now to possess some particle of the universal creative force in virtue of which he can wrest from Nature the secrets so jealously guarded by her and bend them to his own desire."

What has been and can be accomplished in the way of prevention where the causes of disease are known was illustrated by many cases of army experience where complete and comparable statistics are available. For instance, in the South African war at the beginning of the century where the British had only 208,000 troops, there were 58,000 cases of typhoid fever and 8,000 deaths. But in the Great War on the western front with an average British strength of one and a quarter million, there were only 7,500 cases of typhoid and 266 deaths. That is, after inoculation with injections of dead typhoid bacilli, there were fewer cases of the disease in the Great War than there were deaths from it in the African war. In the French army there were 96,000 cases and nearly 12,000 deaths in the first sixteen months before the French adopted vaccination.

Trench fever, which was unknown before the war and of which the germ is still unknown, caused more than a million cases of illness in the Allied armies before 1918 when it was discovered that lice carried the invisible virus. When the louse was eliminated the trench fever went with it. During the first two months of the war, nine or ten of every thousand of the wounded were infected with tetanus and eighty-five per cent. of these died of it. After the introduction of antitetanic serum the cases fell to about one in a thousand and the mortality to less than half.

Typhus fever is also carried by a louse; Rocky Mountain fever by the woodtick; malarial and yellow fevers by mosquitoes, the African sleeping sickness by the tsetse fly, and in all such cases the disease may be eliminated by getting rid of the insects.

Tuberculosis is not so easily dealt with. What Sir David Bruce says on this important question should be quoted directly, since the British Government has adopted very extensive and expensive measures to prevent tuberculosis:

> In regard to the tubercle bacillus it is so widespread, so ubiquitous in civilized communities, passing from one infected host to another, that it would seem impossible under existing conditions to prevent its spread. At present it is taught, and on what seems good evidence, that the majority of the population of our crowded cities has at one time or another been attacked by this disease. But in every hundred men who die in England, only about ten die of tuberculosis, which shows that a large percentage of the population successfully resists the tubercle bacillus.
>
> When this occurs it means that the person attacked possessed powers of resistance which enabled him either to destroy the invading bacilli or to render them harmless.
>
> A point of importance in this connection is that it has recently been demonstrated that the disease is usually acquired in childhood. The fact is of capital significance, for if the disease is recognized sufficiently early, and the child is placed under good hygienic conditions, there is a very good chance of effective resistance and immunity against a second attack being set up. The present evidence goes to show that the presence of latent tubercles prevents a second invasion.
>
> The preventive measures against tuberculosis at the present time are, in the first place, improvement in the general hygienic conditions. Thereby individual resistance—and communal resistance—can be remarkably increased.
>
> In the second place, as every case of tuberculosis must arise from a previous case, either human of bovine, it is very necessary that methods of early diagnosis, preventive treatment, and segregation of the more infective types may be provided for. This is done by the setting up of tuberculosis dispensaries, care committees, sanatoria, hospitals and colonies.

Enough is now known about the essentials of health and the causes of disease to secure for the next generation sounder bodies and safer lives, if man could be allowed to work out his salvation in peace, but as Sir David said:

> To saddle the country with a million and a half of unemployed, with the consequent poverty, insufficient food, clothing and housing, is not calculated to further the prevention of disease and raise the standard of health. It is too much to hope that some time in the revolving years a time may come when by a Confederation or League of Nations the world may be so policed that no one country will be able with impunity to attempt the destruction of its neighbor. Until this happens it is difficult to see how rickets, tuberculosis, and other diseases can be adequately dealt with in our city population.

Lack of Eye Balance May Cause Clumsiness.—The man who is clumsy with his hands, who cannot perform delicate tasks with tools, shoot straight, or play such a game as baseball probably lacks a correct balance between the muscular systems of his two eyes, E. C. Clements, British physician and aviator, told the psychologists of the British Association for the Advancement of Science. This observation resulted from studies of eye disorders which rendered British pilots incapable of landing airplanes successfully during the war. Two factors are involved in successful binocular vision, he said. The impulses which are received from the two eyes must be interpreted correctly by the brain. In response to this stimulus there must be efficient coordination of the muscles responding. In many cases such defects can be removed by special visual training exercises.

Glasses for Colorblindness.—The possibility of at least a partial cure for colorblindness was pointed out at the meeting of the British Association for the Advancement of Science, by H. E. Roaf, M.D., professor of physiology at the medical school of the University of London. "As a result of the examination of color blind individuals," reports Professor Roaf, "it has been found that some of them are sensitive to as great an extent of the spectrum and apparently with intensity equal to that of normal people. Therefore the difficulty of these persons must lie in their failure to differentiate certain wave lengths of light. Such individuals can recognize their mistakes by examination of their color matches through a colored screen. It is possible that if such a person wore a colored glass over one eye, he might learn to recognize colors like normal persons while wearing the glass."

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

E AND A

SUMBUL-AGAR

(Originated by Dr. Max Einhorn, New York)

Each teaspoonful represents 1 cc (m 15) of Fluid Extract of Sumbul U. S. P. It is used with good results in neurotic intestinal disturbances. The agar carries the sedative over a large area of the intestinal tract, and slowly liberates the Sumbul through osmosis. The dose is one teaspoonful in some water, three times daily after meals.

European Cancer Campaigns.—During the last year a number of new campaigns against cancer have been organized in European countries. Some have received official sanction by the national government. In Spain, for example, a League Against Cancer has been created with the King as president. An extensive cancer campaign has been organized this year by the Society for the Eradication of Cancer in the Czecho-Slovakian Republic. Not only has official recognition been given, but a large gift of money has been received from the President of the Republic, T. G. Masaryk. The Franco-Anglo-American League Against Cancer has recently held its annual meeting in Paris, under the chairmanship of Paul Strauss, former Minister of Health.

Correspondence and Reading Courses in Public Health.—For more than twelve months the Public Health Service has been collecting from the executive officers of State departments of health and from the universities with which Class A medical schools are affiliated, data regarding correspondence and reading courses in public health. Reports received to June 1, 1924, indicate that courses have been conducted during the past two years by seven State departments of health and by six universities.

Of the courses given by departments of health, five are for sanitarians—those conducted in Kansas, Illinois, Ohio, New Mexico, and Pennsylvania. In addition, the Virginia State Health Department offers a correspondence course for teachers; in both Virginia and Minnesota a course is given in the hygiene of maternity and infancy for mothers; and a second course is offered in Pennsylvania, one for persons connected with industries, schools, and with civic and religious organizations.

In no case is tuition charged for the courses conducted by State departments of health. Mimeographed or printed lessons are distributed in several instances, and in two cases textbooks are used. Those taking the course are required to answer questions by mail from time to time, in four or five instances in connection with each lesson. The number enrolled varies a great deal, as will be seen in the reports of the various courses; so also does the length of the course.

The correspondence courses offered by universities are in five instances conducted by the extension division of the university and in one case by the department of hygiene. One university conducts only one course; two conduct two courses; two, four courses; and one conducts seven courses. Most courses appear to be offered primarily for those who are now or intend to be engaged in public health work, although a few courses apparently are for laymen. In all cases tuition is charged, textbooks are used, and examinations are given. Academic credit is granted for all courses, except in one university where credit is given when the student is enrolled in the school of education but not when he is enrolled in the school of medicine. The length of courses varies from twenty to forty lessons. While the courses offered by universities may have a more dignified status than those offered by State departments of health, the number of students enrolled, as will be seen, is not so large.

New Publications Received.

Idle Thoughts on Medical Education*

GORDON WILSON, M.D.,
Baltimore

Those of you who have lately reread *Alice Through the Looking Glass* will recall her conversation with Humpty Dumpty on the use of words, and his scornful statement, "When I use a word it means just what I choose it to mean—neither more nor less." I have followed his illustrious example in my use of the word "idle" in my title, and would have it mean that the thoughts were not based upon thorough research in the subject but were incidental to an active interest extending over a period of a quarter of a century in which I have read what came to hand and have taught in clinical courses to a generation of students.

In order to understand present conditions it is necessary to know what might be called the life history of medical education in this country and for the purpose of study, its growth and development might be divided into three periods.

First "the clinical-anatomical," or "preceptor" period, which started shortly after the revolution, (although the first medical school was founded in 1765) and took its inspiration from the English and Scotch schools. At this time medical education consisted in "reading medicine" with a doctor as one "read law," and from this there grew a partnership of doctors in order to better teach a larger group of students and was the beginning of what we now speak of as the proprietary medical schools. The scientific foundation at this period was anatomy, and quite naturally the teachers were the surgeons who had studied in London and Edinburgh, notably Physic, Nathan Smith, McDowell and the Warrens.

The second period began with the return to this country of those Americans who had studied under Louis and Laennec, and "clinical-pathological" might well designate the prevailing fundamentals of this age, and it was from Paris that the inspiration came that made the old world look to the new for the first time for medical knowledge. This second period began about the middle of the century, and its outstanding figures were the internists, Gerhardt, James Jackson, Jr., Austin Flint and Osler.

The third period had its birth in the new path blazed by Pasteur and developed by the German school under Koch and his students. This last period can be well called the laboratory period, and, for the first time in American medicine, the clinical side became subordinate, not only in the title of the period, but in medical education.

MEDICAL SCHOOLS DURING THE FIRST PERIOD

In the first period there was founded, not only the proprietary schools, but also a few schools that might be termed university in character, such as the medical school founded in conjunction with Harvard (1782). The growth of the country was during this time relatively slow as compared with the second period, and the increase in medical colleges was equally slow as compared with this second period when there took place the rapid development of the West, and with it came the demand which resulted in the almost inexcusable mushroom-like growth of medical schools during the last decade of the last century, and the first few years of the present one, culminating in a grand total of 162 schools existing in 1906.

Closely following the birth of the science of bacteriology and immunology came the rapid development of physiology and chemistry, and with the recognition of the importance of these sciences in medical education arose the need of laboratories with expensive equipment, costly to maintain, and manned by teachers who must be paid a living salary and could not look to consultations with their students for their means of livelihood.

It was at the beginning of the last quarter of the last century that certain leaders of our profession awoke to the fact that there was need for the state to scrutinize the diplomas of the increasing number of doctors graduated each year, and then began the examination of physicians by the state board of examiners prior to licensing.

DISAPPEARANCE OF PROPRIETARY SCHOOLS

With the establishment of the expensive laboratory preclinical years came the rapid disappearance of the proprietary schools whose existence had depended upon the fees paid by the students which now failed utterly to meet the cost of conducting these schools, and there remained only those medical schools supported by private endowment on state aid in whole or in part, with the result that today there are only sixty Class A schools graduating physicians.

*Presidential address delivered at the annual meeting of the American Climatological and Clinical Association, May 1, 1924.

REQUIREMENTS FOR ADMISSION

From a time when there was no requirements for admission to a medical school there has developed in my lifetime such demands in premedical education that the average age of graduation today is four years older than it was twenty-five years ago. There is no question that there was, and is, a need for proper educational qualifications preparatory to the study of medicine, but there is some question as to whether the present requirements are not too rigid, and I must confess that I, personally, would prefer that the students that I have to teach had been required to take a course in logic and psychology rather than French or German, and I feel quite sure that it could not be of less use to them in after life than is the French or German now required.

NUMBER OF TEACHING HOURS

In this same twenty-four years, or perhaps a little more, the medical course has grown from two terms of six months each to four terms of eight months with a sharp dividing line separating the first two years devoted to the laboratory sciences, and the last two years to the clinical arts. With the rapid growth of the laboratory sciences, there has been a corresponding development of specialties with the result that today in many schools the student is in the class rooms, laboratories or wards from half past eight in the morning to half past five in the afternoons, and frequently even the supposed Saturday half holiday is taken up by a clinic in a nearby (?) insane asylum or hospital for consumptives. In spite of this stupendous increase in teaching hours every department is clamoring for more time to teach the student when the poor man is so mentally tired that he cannot digest the facts given, that tomorrow may be discarded theories.

PRESENT CONDITIONS UNSATISFACTORY

Today the increasing number of articles on medical education show that conditions are unsatisfactory. What is the solution? Is it whole time clinical heads of departments? Is it elective courses, and if so in what years should such election be allowed, and to what extent? Is it in doing away entirely with didactic teaching, and substituting entirely case teaching? How can correlation in teaching be brought about, and what is its value? Ought we to put more clinical teaching in the first two years and more laboratory work in the last two? Shall we add one more year to our present four year course in order that a little of the clamoring shall be stilled? All of these questions have been brought up as well as many others, and they show that medical education today is in a period of flux, and one is not quite sure that the outcome will be satisfactory.

It is almost axiomatic that the greater the number of drugs recommended in treatment the less is known of the etiology, and applying this to medical education we realize we are treating symptoms with these therapies and have failed to search for the cause of the condition.

PROPER ORGANIZATION IMPORTANT

In war, and in peace, success depends not only upon the unification of command in proper leaders, but also upon proper organization, and the great industries of this country have demonstrated this to the world, and perhaps we can learn something from them as they learnt something from us when they established research departments, but they did not make the head of the research department the president of the corporation. Perhaps the solution of the question may be found by asking what is the object of a medical board, and the answer is found in the product of a medical school and at once we get the answer that over seventy-five per cent. of those graduating become practitioners, a small number specialists, a still smaller number teachers, and a few, with the divine spark, become that small coterie who advance the science by research. This last group are the great artists of medicine, and like the great artists of the world are never made by teaching the common clay, but are born and achieve greatness frequently in spite of the lack of facilities.

A commercial organization properly organized would devote its capital and its plant to its different products in proportion to their relative quantity and value, and perhaps if we were to ask advice from the industrial world we would be told to follow their example. With these facts before us we can frame a definition of what is the object of a medical school that will clearly set forth our raw material and our finished products, with their relative value and our means of manufacturing that permits a maximum use of plant.

OBJECT OF A MEDICAL SCHOOL

The object of a medical school is to educate properly qualified men and women to become practitioners of medicine, and in so doing to give them the foundations whereby with further study they may become specialists, teachers, or research workers. With this definition before us we are in a position to see that the teaching in all departments, especially of the clinical years conforms to it, and the poor medical student no longer has to learn the technic of a cystoscopic examination, but simply the indications for it and its limitations.

Having defined what is the object of a medical school, it might be advisable to realize that a medical school is a *professional* school and not a postgraduate school, terms not synonymous in spite of the authority of many inaccurate thinkers, and with this realization the proper position of research at the expense of knowledge of fundamentals is at once evident, both for the student and the teacher.

LABORATORY SCIENCES CONFIRMATORY

A third cause, perhaps, for our unrest today is the failure to realize that the laboratory sciences are confirmatory rather than diagnostic and might be compared to a superior court where relatively few cases are taken, and where the decisions are not always for or against the plaintiff, but frequently the court sends back the case to the lower court for retrial.

Idle thoughts rarely in themselves, or their author, accomplish much, but at times they do stimulate, and today in medical education there is need to stimulate the proper teaching of clinical medicine, founded not on theories but accepted facts, to the end that humanity may suffer less.

4 East Preston Street.

Surgical Treatment of Angina Pectoris*

With Report of One Case

CHARLES GODWIN JENNINGS, M.D., and
ALPHEUS FELCH JENNINGS, M.D.
Detroit, Michigan

In 1899 Franck (1) suggested resection of the left cervical sympathetic ganglia for the relief of the pain of angina pectoris. He found that the typical distribution of the pain of angina makes it certain that the paths of conduction of the pain are through the cervical sympathetic trunk and ganglia and the posterior roots of the related spinal nerves.

Jonnesco of Bucharest was the first to act upon the suggestion of Franck. In 1920 he reported the cure of a case of angina pectoris by resection of the left cervical sympathetic. The patient was operated upon in 1916.

Coffey and Brown of San Francisco (2), reported five cases of angina treated by resection of the left cervical sympathetic with marked improvement in four cases and death in one case.

Wenckebach (3) in a lecture on angina pectoris delivered in this country last summer stated that five patients had been operated on in this clinic under the care of his assistant, Eppinger. Four patients recovered with complete relief from the angina. One died suddenly two weeks after the operation. The operation in Wenckebach's clinic was resection of the left depressor nerve as it courses up the neck in the sheath of the vagus. In the fatal case both right and left depressor nerves were resected.

Among two hundred cases of sympathetic resection for various conditions performed by Jonnesco since 1920, there were three more cases of angina pectoris, in all of which the patients were cured by the resection of one or both nerves. Tuffier, in a discussion of Jonnesco's first paper, reported three successful cases.

Halstead and Christopher (4) of Chicago reported one case this year.

This series of operations, to a certain extent experimental in character, is of great practical interest.

First, as a contribution to the elucidation of the pathology of angina pectoris; and of the anatomy and physiology of the sensory nerves of the aorta and heart—and,

Second, as the development of a successful method of treatment of this very grave and painful disease.

You all are familiar with the controversies which have waged since Heberden's first description of angina pectoris in 1768 over the pathological nature, the seat of the lesion and the cause of the pain in this disease.

The exhaustive study of angina pectoris by Sir Clifford Allbutt (5) considers at length all the factors in the controversy, and his conclusions, based upon his own very full clinical and pathological observations and a critical study of a great mass of literature from Heberden's original report down, we believe to be sound and, furthermore, at this time appear to be supported by the successful results of the surgical treatment of the disease.

The symptom complex to which Allbutt restricts the term angina pectoris, of which substernal pain is the most prominent factor, is aortic in its origin. It is excited by tension and stretching of the aorta made hypersensitive by pathological changes at the root of the vessel, either atheromatous patches or areas of infectious aortitis—syphilitic, influenzal, rheumatic, etc.

Pathological changes in the heart alone, in the myocardium, pericardium, endocardium, valves or nutrient vessels, do not cause this peculiar symptom complex. Disease of these structures gives rise to painful manifestations, but such cardiac pains have not the distinctive features and the characteristic distribution of angina pectoris. It is a fact familiar to all clinical observers that diseases of the heart, whether acute or chronic, usually pursue their course even to a fatal termination without, at any stage, being attended by an attack of angina. It also has been demonstrated that fatal angina may occur and autopsy reveal a normal heart and pathological changes restricted to the suprasigmoid area of the aorta.

It is true that exceptionally angina may appear during the course of heart disease. The significance of this is that in addition to the disease of the heart there is a complicating pathological process at the root of the aorta.

Anatomical and physiological studies have not as yet determined with certainty either in the lower animals or in man the pathway of the sensory or afferent nerves of the heart and aorta.

The positive results of section of the cervical sympathetic in arresting the pain of angina indicates that in that situation at least the pathway is along the bundle of fibres including in this nerve trunk and its ganglia.

Sympathectomy was the operation selected in all the reported cases including our own, excepting those of Wenckebach. Wenckebach from his studies looked more to the depressor nerve as the first afferent that would be the pathway of the pain.

The physiology of the depressor nerve is given by Howell as follows:

"Among the many depressor affects that have been observed on stimulation of the afferent nerve fibres one has aroused especial interest — namely, that caused by certain afferent fibres from the heart or from the aorta. These fibres in some animals—the dog, for instance—run in the vagus nerve, but in other animals, the rabbit, they form a separate nerve, the socalled depressor nerve of the heart—discovered by Ludwig and Cyon (1866). So far as the effect in question is concerned the physiological evidence indicates that the fibres arise from the aorta, and it

*Read before the American Theropeutic Society, at the annual meeting held in Toronto, June 6, 1924.

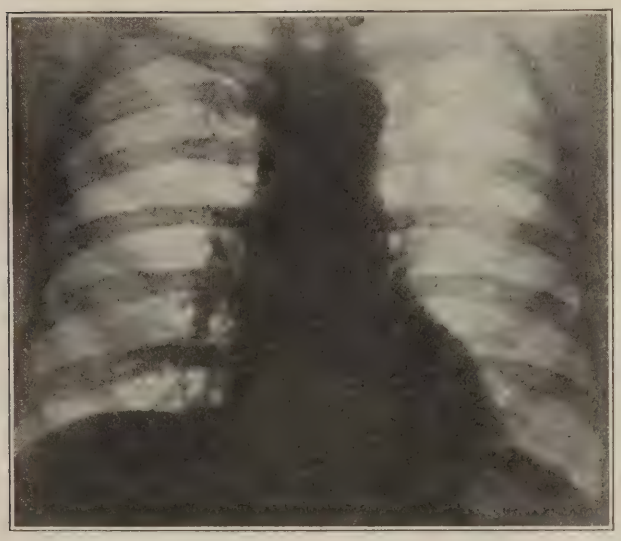

Fig. 1.—Left ventricular hypertrophy and aortic dilatation.

might be more appropriate to speak of them as the depressor nerve of the aorta. In the rabbit this nerve forms a branch of the vagus, arising high in the neck by two roots, one from the trunk of the vagus and one from the superior laryngeal branch. It runs toward the heart in the sheath with the vagus and the cervical sympathetic. The nerve is entirely afferent. If it is cut and the peripheral end is stimulated no result follows. If, however, the central end is stimulated a fall of blood pressure occurs and also perhaps a slowing of the heart beat."

Studies by David Ferrier and by Koerster indicate that the depressor is in reality the sensory nerve of the aorta.

Concerning this nerve Wenckebach says in substance:

It is true the depressor has something to do with the lowering of blood pressure, but certainly its anatomy is very vague, not only because its course is different in different animals, but also because in the same group of animals, for instance in man, the depressor nerve has individual variations. It is remarkable also that the depressor nerve runs through the same sheath as the vagus.

The operation made in Wenckebach's clinic—the details of which have not as yet been published—was resection of the depressor nerve as it courses within the sheath with the vagus. Until Wenckebach's cases are reported in full it is not possible to decide which is the preferable procedure. Apparently resection of the depressor fibres alone before they merge with the sympathetic would be better. Although it is technically more difficult, it may avoid the undesirable ocular and other side effects of section of the sympathetic fibres.

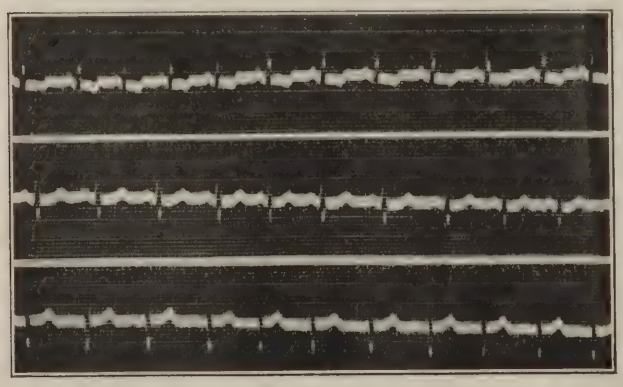

Fig. 2.—Electrocardiogram. Slurred QRS complex and inverted T wave in lead I.

Case.—Mr. E. E. M., aged forty-one, unmarried, salesman. The patient's father, F. H., died at seventy-nine from apoplexy, mother at fifty-six from mitral stenosis, one brother died from tuberculosis, one from accident, one sister died from pernicious anemia, and one from puerperal accident. There are two brothers and two sisters living and well.

The patient had had the usual childhood diseases, typhoid fever as youth, appendicitis unoperated at twenty-five, pneumonia in 1918. Bronchial asthma began 1917 after exposure to smoke in a large munitions fire. Attacks were brought on by excitement and overeating, and relieved by adrenalin, of which he took repeated doses. This became much improved after removal of tonsils and some bad teeth, and surgical drainage of infected nasal accessory sinuses. Attacks of gallstone colic occurred at intervals. In September, 1923, empyema of the gallbladder occurred and it was drained surgically.

Fig. 3.—Enophthalmos and ptosis following sympathectomy.

Arterial hypertension was first discovered in 1918. This did not subside after cleaning up many foci of infection. In May, 1922, the patient suffered a right sided hemiplegia with motor and sensory paralysis. Complete recovery occurred in several months. The angina pectoris began a few months after the hemiplegia. The attacks began rather mildly, but increased progressively in severity. The pain was precordial, radiating down the inner side of the chest, that caused anxiety more than did the pain. The attacks of pain came by periods. For a few days they would be mild and relieved by amyl nitrite. Then would occur a severe attack. From one half to three quarters grain of morphine would be necessary to quiet the pain. After this the pain would wear off slowly during the course of several days, and after a rest of a week or so he would be back at work. Between the hard attacks there would be lesser ones relieved by amyl nitrite. The pain was usually brought on by exertion, excitement or overeating. It became more and more constant and eventually completely disabling. At this stage any attempt to leave his room resulted in recurrence of more or less pain.

The physical examination showed a blood pressure varying from 180 to 220 systolic and 110 to 140 diastolic. The left ventricle was enlarged to percussion and to x ray, and the aortic arch was enlarged to x ray. The lungs showed marked hyperresonance and a few piping râles. The abdomen never showed tenderness or spasm until

the acute cholecystitis developed. The foci of infection in the teeth, tonsils and sinuses showed the usual signs which disappeared when recovery took place. The skin of the chest, upper abdomen and back between the shoulders showed a macular pigmented rash, which came and went. The fundi were normal.

The blood was negative and the blood and spinal fluid Wassermanns were negative. The blood uric acid varied from 3.7 to 4.5 mgm. per 100 c. c., and the noncoagulable nitrogen from thirty-three to forty mgm. The phenolsulphonephthalein was eighty-five to sixty-five per cent. on separate occasions and the Mosenthal test was normal. The spinal fluid showed a normal gold curve and mastic, and absence of globulin.

The x ray of the gastrointestinal tract was negative. The urine showed at times a little albumin and a few casts. Electrocardiograph showed inversion of the T wave in lead I, notched QRS complexes in all leads and inverted R wave in lead III. Frequent tracings showed no variation. One tracing was taken during an anginal attack and one during convalescence.

The patient was operated upon on April 8, 1924, by Dr. J. W. Vaughan, who made the following notes of the operation: Anesthetic administered was ethylene gas. After the usual skin preparation an incision was made along the posterior border of the sternocleidomastoid muscle of about seven inches in length. The method followed was that so thoroughly described by Jonnesco (6). The sternocleidomastoid muscle was reflected forward with the exception that the incision was carried slightly into the muscle at the superior end of the posterior margin in order to avoid injury to the lesser occipital nerve, which was exposed. The great auricular nerve was also exposed for a length of about two inches without other injury to that structure. The spinal accessory nerve was exposed as well for a distance of about one and one half inches. The greater vessels of the neck were brought into view by retracting the sternocleidomastoid muscle forward and the vagus nerve was seen running in the sheath of the great vessels. Running along the anterior surface of the longus capitis muscle a nerve was encountered whose position accorded with that of the cervical sympathetic. However, upon tracing upward and downward for a distance of three inches no ganglion could be found. Nevertheless, when this nerve was injured by pinching with forceps, the pulse rate immediately increased to 120 a minute. It was, therefore, thought that we must either have a sympathetic nerve which did not possess the characteristic text book description of its ganglion, or that the depressor nerve had been encountered after its separation from the vagus. Consequently a piece about three inches in length was excised from this nerve. The wound was then closed by means of catgut sutures and interrupted silkworm gut for the skin, no drainage being used. The operation was completed in thirty minutes.

The steps involved in this operation have been reported somewhat in detail for the reason that the resulting postoperative phenomena observed can thus be more easily explained. For the first few days there was numbness in the shoulder and behind the ear, after which the pain in these localities became quite excruciating. No anginal attacks occurred, but it could be readily seen that the stretching of both the great auricular and the accessory nerves was accountable for considerable discomfort, which lasted over a period of about four weeks. After this, sensation in these localities returned to normal. This would possibly be a good argument for the method of approach advocated by Mayo along the anterior border of the sternocleidomastoid muscle in preference to that of Jonnesco.

The period which has elapsed since the operation is approximately two months. The patient has been operated upon for a postoperative abdominal hernia, which followed gallbladder drainage for gallstones and pancreatitis. No painful anginal attack has occurred since, but upon three occasions during the first two weeks the patient complained of all the symptoms of angina except the pain. Since then there has been no recurrence of such phenomena.

COMMENT

In the foregoing are cited twenty-one cases of operation for angina pectoris with nineteen recoveries and two deaths.

In sixteen cases the operation performed was resection of the cervical sympathetic; in five cases resection of the depressor nerve. Relief of the anginal pain was more or less complete with both operations. Either operation, therefore, cuts the pathway of the sensory nerves from the pathological field in angina pectoris. Whether this field be the aorta alone as contended by Allbutt and others, or the aorta plus some areas of the heart structure, is still an open question. This question cannot be answered until the peripheral distribution of the nerve fibers severed is finally determined. The pathway of the afferent, sensory nerves from the aorta or aorta and heart to the cord and medulla also is not determined. From the success of Wenckebach's resection of the depressor nerve it would appear that in the lower neck this nerve carries all the sensory fibres, which, as shown by the equal success of resection of the sympathetic, must join the sympathetic at some point below the superior cervical ganglion.

It is too early to make positive statements as to the ultimate results of the operation. The evidence to date is that it relieves the pain of angina pectoris. There is no reason to believe that the operation will affect, one way or the other, the pathological process in the aorta or heart which excites the pain. The ultimate prognosis will depend upon the character, the extent and the progressiveness of the underlying disease. The primary atheroma or aortitis may recover, may be arrested or it may extend and involve larger areas of the aorta, the coronary arteries, the cardiac valves or the myocardium. Disaster may come from aortic rupture, aortic valve disease, coronary occlusion or myocardial degeneration.

If the theory of cardiac arrest from reflex vagus stimulation through the sensory nerves from the aorta as the cause of sudden death in angina pectoris be correct, this result may be averted by the section of the sensory limb of the reflex arc.

The immediate danger of the operation is not great.

"Jonnesco relates that since 1896 he has resected the sympathetic nerve on both sides in two hundred cases, usually including the first thoracic ganglion. The operation was done to relieve epilepsy, exophthalmic goitre, angina pectoris, migraine or for other indications. Reexamination from five to twenty-four years afterward has never revealed the slightest unfavorable influence on the heart from this total bilateral sympathectomy."

Experience also shows that the ocular and other side results of cervical sympathetic division gradually recover.

Finally, it may reasonably be stated that in certain selected severe cases of angina pectoris, which have resisted medical therapeutics and which have made life unbearable, surgical resection of the depressor nerve or the cervical sympathetic gives a fair prospect of relief from the terrible pain and perhaps offers a chance of permanent cure.

Inflammatory Diseases of the Breast*

ARTHUR J. PARKER, M.D.
Brooklyn, N. Y.

Under inflammatory diseases are considered all those affections connected with the activities of bacteria in the tissues. The familiar simple engorgement and caked breast, although they respond to the same treatment as the milder infections, are not included because bacterial invasion is not a factor in their causation.

Reviewing the etiology we find that breast inflammations occur almost exclusively in nursing women, less frequently during pregnancy, in the nonpregnant and in early infancy, rarely at puberty in both sexes and in the adult male. Of the nursing women those most frequently affected are the primiparæ.

The usual organisms cultured from mammary infections belong to the staphylococcus and streptococcus groups, but many others, such as pneumococci and coli bacilli, have often been found predominating. More rarely the breast is invaded by vegetable parasites other than bacteria, e. g., the ray fungus and blastomycetes. The spirochæta pallida and tubercle bacillus are occasionally responsible for the chronic inflammatory conditions.

A break in the continuity of the nipple or the skin covering the breast is the most common portal of infection. Extending along the milk ducts or lymphatics the infection reaches the lobes or interlobular tissue of the gland. Rarely the breast is involved during the course of a septicemia or is metastatically infected from a distant focus. De Lee in 1893 found staphylococci inhabiting normal breasts and it is easy to conceive of these causing inflammation in tissues weakened by injury.

Given the portal of entry there are certain conditions which favor invasion: those which bring bacteria to the tissues and those which interfere with protective reaction on the part of the body. Among the former are lack of cleanliness in caring for the nipples, an unclean breast pump, and the presence of infection in the mouth, eyes or ears of the nursing infant. The main factors in weakening the defensive forces are illness, engorgement of the breasts and trauma in the form of a blow, improper massage or rough handling of the organ.

The types of inflammation encountered in the breast may be classified under the general headings of acute, chronic and malignant with several subdivisions.

A. Acute: 1. Ulceration of the nipple. 2. Abscess of areolar sebaceous gland. 3. Subareolar abscess. 4. Cellulitis. 5. Galactophoritis. 6. Breast abscess.

B. Chronic: 1. Chronic mastitis. 2. Chronic abscess. 3. Inflammatory conditions due to syphilis, tuberculosis and vegetable parasites other than bacteria.

C. Malignant:

ACUTE INFLAMMATIONS

Ulceration of the nipple is the result of bacterial action on an abrasion of the delicate skin in this region and is exceedingly important in its causative relation to deeper breast infection.

A collection of pus beneath the areola tends to point through its thin pigmented covering rather than extend through the deeper, more resistant structures and is known as a subareolar abscess.

Cellulitis of the breast may involve only the skin and its subjacent cellular tissue or affect the cellular tissue of the entire gland. Abscess formation may complicate both types. The diffuse variety is a probable causative factor in chronic mastitis.

A purulent discharge from the nipple may be due to infection of the milk ducts or galactophoritis. The glandular elements alone tend to become involved by extension of this process, but any degree or type of infection may result.

Abscesses are best classified according to their location as superficial, interlobular, intralobular, multilocular and retromammary. The superficial, found in the fatty tissue just beneath the skin, are due to the softening of a superficial cellulitis or direct extension from a cutaneous infection. When infection is carried by the lymphatics to the interlo-

*Service of Dr. Charles Gordon Heyd.

bular connective tissue and fat a resulting abscess is called interlobular or supramammary. Suppuration limited to the glandular elements is called an intralobular, parenchymatous or inframammary abscess. The retromammary type is caused by lymphatic or direct extension to the loose tissue behind the breast. A multilocular collection of pus may be a combination of any or all of the other varieties of abscess communicating one with another. This type is common.

CHRONIC INFLAMMATIONS

The most frequently occurring chronic condition is chronic mastitis defined by Rodman as, a chronic inflammatory process affecting the mammary gland: characterized by the formation of fibrous tissue which results in the compression of the acini and ducts, leading to atrophy and cystic formation.

Abscesses due to low grade infection may remain in the breast for years and have often been mistaken for malignancy because of enlargement of the axillary glands, retraction of the skin, or sanguineous discharge from the nipple. Such abscesses are found most frequently in women of the cancer age and may be due to the infection of a hematoma or cyst. Occurring in the retromammary space these infections, according to Lyle, are most often the result of conditions arising external to the breast such as extension from necrosis of the ribs or perforating empyema. Abscesses of tuberculous origin are not included under this heading.

Syphilis, when it appears in the breast, as it may in any stage, is diagnosed and treated in the same manner as syphilis in any other part of the body.

Tuberculosis of the breast resembles any other chronic inflammatory process but since it is rarely primary it can usually be traced to a focus in some other part of the body. Amputation supplemented by general treatment is probably the best procedure.

The rare conditions caused by vegetable parasites other than bacteria give the symptoms of a low grade infection, are unusually resistant to treatment and may be best diagnosed by microscopic examination of the discharge. The treatment is radical surgery plus large doses of potassium iodide.

MALIGNANCY

Although there is no particular type of infection classified as malignant, in thinking of infections it is well to remember that abscess and malignancy occasionally coexist as a rapidly fatal combination, and also that any eczematoid infection in the region of the nipple which resists ordinary treatment may be an early manifestation of Paget's disease.

PROPHYLAXIS

Preventive measures are most important in the treatment of breast infections. Care of the breasts cannot be instituted too early. During pregnancy the nipples should be frequently bathed, dried and coated with albolene. A soft nipple is less susceptible to injury. Deformed or depressed nipples may possibly be improved by daily gentle traction. Cleanse the nipples before and after nursing with a saturated solution of boric acid. Between nursings they may be coated with a mixture of castor oil and bismuth equal parts and be kept covered by a sterile dressing. Breast pumps, feeding shields or any article coming in contact with the breast must be thoroughly sterilized. Sore nipples must be carefully inspected for fissures which if found demand immediate treatment.

TREATMENT

Ulceration of the nipple is treated by application twice a day of two per cent. silver nitrate solution. A lead nipple shield may be worn between nursings if a sterile dressing is not feasible. To prevent trauma a glass nursing shield may be used. The slightest neglect is almost sure to result in deeper infection.

Subareolar and sebaceous gland abscesses are incised as soon as diagnosed. They are dangerous because of their location near the nipple which must be protected as carefully as possible by measures previously mentioned.

When a patient ten days postpartum complains of pain in the breast, has a slight temperature or perhaps a high temperature preceded by a chill, breast infection should be suspected. Cellulitis if superficial will show inflamed lymphatics, if deep a brawny induration of the skin is present. A purulent discharge from the nipple indicates a galactophoritis. An abscess is diagnosed by the presence of a tender mass, acutely inflamed, with or without fluctuation. If retromammary the whole breast is pushed forward by the process and its base is surrounded by an area of edema.

The early treatment of all infections is the same. A supporting binder and an icebag are applied. Massage and breast pump if resorted to in galactophoritis must be used with the greatest caution by a skilled attendant. Nursing is suspended. The patient is placed on a dry diet and given a saline purge. Fluctuating areas demand immediate incision and drainage.

Due to the arrangement of the connective tissue in the gland nearly all breast abscesses are crossed by numerous septa or are multilocular. A small incision is valueless. Superficial abscesses are treated by wide radiating incisions. Septa must be cleared away by the surgeon's finger. Rubber is used for drains.

Deep and multilocular areas of suppuration are best approached and drained through a liberal incision at the inferior thoracomammary junction. This incision first described by Thomas should be used whenever possible because: 1. It gives easy access to the entire gland. 2. It gives ample exposure and leaves no visible scar. 3. With the breasts bound up the opening for drainage is at the lowest point.

After operation wet dressings frequently changed give the best results. An autogenous vaccine may hasten recovery.

Chronic abscesses may be dissected out or drained through a thoracomammary incision. If confused with malignancy, aspiration will help to clear the diagnosis.

Chronic mastitis is usually found in both breasts, has a history of long duration, slow progress, and the mass is never adherent to the deeper structures. When sure of the diagnosis support, massage, and x ray may be supplemented by potassium iodide internally. Amputation or ablation of mammary tissue is the final resort and safest procedure.

190 Hancock Street.

What the Cystoscopy of Today Means to Physician and Patient*

P. S. PELOUZE, M.D.
Philadelphia, Pa.

One approaches a subject of this kind with a great deal of hesitancy when he realizes that little of what it really means is reaching the patient and, in fact, even the physician. For the real value of the cystoscopy of today is little appreciated by the greater number of physicians and few patients have ever heard of such a procedure. It is singular how many years are often required for some of the great advances in medicine to become common knowledge among physicians.

In this connection it is of interest to recall that cystoscopy was born in 1852; that lens cystoscopes were being used in 1868; that Edison gave us the incandescent lamp in 1876, and that three years later it was used for cystoscopic illumination. Modern cystoscopy can, therefore, be said to be forty-five years old.

We are generally credited as being a body particularly alert to seize upon everything that is truly for the benefit of the health and wellbeing of our patients. It is thought by our patients, and almost everyone is some doctor's patient at some time, that we have minds that are constantly appraising the values of methods of diagnosis and treatment and seeking to give the very best to them. They often choose us because they like us personally, and that personal admiration engenders in them a high regard for our sagacity, a deep conviction that their most valued possessions, health and life, are safest in our hands, and it is with the knowledge of such a state of mind upon their part that we accept their fees. They do not realize the utter impossibility of a single mind holding more than a small part of the sum total of medical knowledge; they only know that we are their doctors and they, thereby, place upon us a responsibility that must not be lightly carried.

If we were to consider carefully our response to such a state of mind upon the patient's part we would be surprised to find how often we have to seek knowledge upon various subjects because the public press has caused the patient to ask it of us. We know much of the use and limitations of the x ray and radium, of toxin antitoxin and of insulin, and much of it is for this reason. The laity knows much of the bronchoscope because of its dramatic presentation to them in the news of the day and they would be very quick to demand its use upon the slightest indication. On the other hand, because the cystoscope is used upon a part of the anatomy not especially featured in the public press, they do not know that there is such an instrument and cannot demand its use.

Every physician knows, however, of the cystoscope and that, where the bronchoscope is of the utmost value to one patient, the cystoscope is of perhaps equal value to hundreds and yet it is not used even a small percentage of the times it should be used. There is not a community of any size wherein its use is not indicated many, many times every year and yet, as compared with the number of workers in many less important fields of medicine, the percentage of skilled cystoscopists is deplorably small. That this is true is evident upon even the most superficial study of conditions as they exist today, and, being true, it merits serious consideration of the question from its various angles.

Before going into the reasons let us briefly consider present conditions in this regard. In the first place many hospitals in this country do not even own a cystoscope; many more own a cystoscope but have no member of the staff who knows how to use it and many more in which, though it is occasionally used, no one has done enough work with it to make his findings safe for either patient or surgeon. Further, we can name a number of towns ranging in population from a few to many thousands in which there is neither a cystoscope nor a cystoscopist; in which a cystoscopy is never done but in which bladders are opened and kidneys operated upon many times each year.

THE REAL VALUE OF CYSTOSCOPY

We are extremely fortunate today in having at our command a truly remarkable number of cystoscopes of different types which make it possible to carry out our cystoscopic procedures upon the infant as well as the adult, so that there is no age at which such a study cannot be made.

With these instruments we can distinctly see the entire inner surfaces of the bladder and urethra in both the male and female. We can with great ease pass catheters into the kidney pelves and thereby carry out close and accurate studies upon the kidneys separately, such as obtaining the urines without bladder contamination for microscopic, chemical and bacteriological studies and a determination of the actual functional capacity of each organ. By the injection through these catheters of substances casting an x ray shadow we can demonstrate the presence, position, mobility and amount of destruction of the kidneys as well as the size and contour of the kidney pelves and ureters. We can without opening the bladder remove foreign bodies of considerable size, destroy vesical papillomata before they become carcinomatous, crush calculi under visual conditions and do a host of intravesical procedures far too numerous to recite.

Consider, therefore, the ideal position of the surgeon of today compared with many years ago. He can almost detach himself from the patient's highly misleading subjective symptoms and can have before him preoperative findings of the most attractive accuracy. He need no longer cut down upon the supposedly good kidney to prove that it is there but can be shown otherwise that it is not only there but its size, position, functional capacity and the character of urine that it excretes. He thus knows whether or not he dare remove an offending organ or must of necessity conserve it.

*Read before the Tricounty Medical Society, Harrisburg, Pa., June 26, 1924. From the Department of Urology, University of Pennsylvania.

In prostatic and in bladder operations his position is even more secure for he can be led by actual preoperative visualization and can carry out his operative procedures accordingly.

All of these things and more are true and still cystoscopy stands as our most greatly neglected diagnostic procedure. To illustrate more forcibly and accentuate this statement a few of the far too many human documents in the shape of brief case reports force themselves forward. Your community as well as my own can produce countless ones that are equally striking.

Case I.—W. D. had a profuse hematuria at twenty-five years of age and consulted a urologist who knew how to use the cystoscope but did not like to do so. He was given some tablets, told to rest in bed and saw no blood in his urine for ten years. He then had a profuse hemorrhage and upon cystoscopy proved to have a large carcinoma apparently secondary to a papilloma which was undoubtedly the cause of his former bleeding. He died because the initial hematuria was not cystoscopically studied, for such a study would have revealed a papilloma amenable to destruction by fulguration and subsequent observation would have prevented unknown recurrences.

Case II.—Mrs. R. was the mother of four children and between caring for them and her home and arising many times at night to void, she had little time for rest or pleasure. Her family doctor treated her for cystitis for four years without improvement. He then sent her to a gynecologist who also made a diagnosis of cystitis and carried out bladder lavage for a year and she was no better. Finally it was decided that she might endure a cystoscopy. The cystoscopist found a contracted tuberculous bladder secondary to an almost functionless tuberculous kidney. A surgeon removed the kidney, the bladder cured itself and now she is able to get some uninterrupted sleep.

Case III.—Mary B. at twelve years of age was seized with an acute pain in the right upper quadrant. There was a high temperature, some rigidity and decided tenderness throughout the entire right abdomen. The urine contained considerable pus. An emergency appendectomy was done upon a normal appendix and the temperature still stayed high. Attention was then turned to the pyuria and a catheter passed into the right kidney pelvis evacuated a large quantity of pus and the temperature came to normal and remained there. A preoperative investigation of the cause of the pyuria would have prevented a needless operation upon the little girl.

Case IV.—H. G. had pain over the left kidney, vesical irritation and much pyuria. The kidney was large and tender and its removal was advised. A preoperative differential kidney test showed that this large, tender, painful kidney was so because the other one that had never been painful had slowly undergone a tuberculous destruction. After removal of the tuberculous kidney the pain and tenderness in the one that had undergone a compensatory hypertrophy disappeared. In other words the cystoscope saved the surgeon much chagrin.

Case V.—John A. had been unable properly to empty his bladder for some months and had had one attack of acute retention. He was sent into the hospital for the removal, because of his age, of a somewhat enlarged prostate per rectum and a large quantity of residual urine. A preoperative cystoscopy showed a trabeculated bladder that sloped very nicely down to an unobstructed outlet. Taps upon the patellar tendons showed an entire absence of knee jerks and the neurologist and the spinal Wassermann confirmed the diagnosis of tabes. He still has his prostate.

Case VI.—Mrs. W. had frequency of urination, great burning and marked pyuria. After several years' treatment by her family physician she was sent to a prominent gynecologist who did a plastic operation upon her perineum without any relief. Feeling later that he had not entirely corrected a cystocele he reoperated. From this she failed to get any relief whatever. After nine years more of agonizing bladder discomfort a cystoscopic study was thought of. This revealed a typical tuberculous bladder with advanced bilateral renal tuberculosis. As there had been no change in her symptoms during all of these years, except to become more severe, there was little room for doubt as to the original and only cause of her illness. She had gone far beyond any hope from surgical intervention.

Case VII.—Dr. X had a friend who suffered from a constant renal pain with paroxysms of ureteral colic and some pyuria. He decided, without any cystoscopic study, to explore the kidney and, not liking its looks, he removed it. Unfortunately it was the only kidney his friend had. A careful cystoscopic study would have revealed this.

Case VIII.—I. M. H. spent two years under his physician's care for frequency and burning of urination. He then entered medical college and during his first few months there had a diagnosis of colon bacillus pyelitis made because he had pyuria and there were colon bacilli present. Toward the end of his third year it occurred to him that it might be well to consult an urologist. He was then cystoscoped and found to have a tuberculous bladder, kidney and prostate. The colon bacilli were still in the urine but there were many tubercle bacilli also. Beside this, when the urogenital findings were made known, the internist found so much pulmonary involvement that he advised him to discontinue his medical course.

WHY IS CYSTOSCOPY NEGLECTED?

There are many factors entering into the correct answer to this question and most of them are easily brushed aside by explanation. For this reason it is of value to discuss briefly some of the more important.

1. There is a feeling rather general among physicians that cystoscopy is an ordeal so unpleasant, painful and fraught with such dangers that very few patients should be subjected to it. The shortest answer to this is, that it is not so. Why should cystoscopy upon the vast majority of patients be any more painful than the passage of a metal sound? It is not! But, if it were, it tells more than hours of guessing. As a matter of fact, with the proper delicacy of touch and a thorough knowledge of the urethra and its sensitive areas, one should be able to do a cystoscopic study upon almost every case with little if any real pain and usually only slight discomfort. The exceptions are in those with vesical

tuberculosis and those very rare patients with extreme urethral hyperesthesia, and here we have and use caudal anesthesia.

2. There is too much reliance upon the value of the subjective and objective symptoms of urogenital conditions. There is no place in the human body where they more often mislead. Volumes could be written upon their vagaries but reliance upon them has caused thousands of useless and illadvised operations. To him who intelligently uses the cystoscope over a long period of time there comes the conviction that they were given to the patient for but three reasons, viz., to make him consult his physician, to immediately intrigue the physician into an erroneous diagnosis, and to point the direction of careful study.

3. Many physicians have never seen a cystoscopy and have but the most vague ideas of what can be accomplished by it. They do not know that, by the use of our modern methods, the margin of error in urogenital diagnosis can be reduced probably as low as two per cent.

4. There is not enough encouragement, either professional or financial, to tempt the younger men to devote the time and attention to the subject that it really requires to become efficient in it. In every community of size some physician should be encouraged seriously to take up the subject, not as some surgeon's assistant but as the consultant of his fellow physicians, for the internist has as much need of careful, reliable cystoscopic work as has the surgeon.

5. There is a lack of general knowledge regarding the indications for cystoscopy. The cystoscope is indicated in almost every chronic condition involving the conducting structures of the genitourinary system; in every case of hematuria, most cases of pyuria and wherever a safe diagnosis of surgical renal disease is to be made. Judiciously used it will reduce guesswork to certainty, place the treatment of these diseases upon a scientific basis and will decrease the mortality and morbidity in urogenital diseases to a very attractive minimum.

6. It is the impression that there are many contraindications to cystoscopy whereas there are so few real ones that it requires but one sentence to give them. They are: very acute inflammation of the lower tract, particularly gonorrhea, advanced pulmonary tuberculosis, severe chronic nephritis and any low physical states. In the three last the procedure at times produces a physical shock that may prove fatal and, excepting the above, almost all of the rest of humanity may be cystoscoped.

WHAT SHOULD BE DONE?

Beyond a doubt the time is here when the shrewd guess based upon urological symptoms should at least be checked up by the means of diagnostic precision at hand. Among these the cystoscope and the various procedures that this instrument makes possible take a preeminent place. Without them diseases of the upper and lower tracts are shrouded in doubts of such complexity that their solution is mere conjecture and is seldom safe for either physician or patient. This being the case, I would strongly urge upon every group of physicians the great advantage of encouraging some one of their number to take up the subject very seriously. This he cannot do without their cooperation for he must study many cases to be of greatest value to them. In this connection it must not be forgotten that many of the studies are difficult and time consuming and unless our patients are impressed with the importance of his studies his remuneration is hardly likely to be commensurate with the services rendered.

In urology we have inherited a large number of fallacies from our forefathers to which we have clung most tenaciously. They may have served well then but many of them have grown very archaic and should be dropped or, at least, placed among medicine's curios. As we thus lay them away certain clinical and cystoscopic facts stand out so strongly that they should be made extremely familiar to us. With this thought in mind I am going to repeat in a brief dogmatic way some of the more important of them, realizing that there are exceptions to almost everything in life.

IMPORTANT POINTS IN CYSTOSCOPY

1. Cystitis is almost always a symptom and not a disease.

2. Frequency of urination is often the first symptom of grave disease and merits the closest study.

3. Hematuria is almost always due to a lesion of such gravity that it will cost the patient's life or health if not corrected.

4. Pyuria may be equally as important to the patient as hematuria.

5. Renal tuberculosis is usually called cystitis for several years. It is generally unilateral at first and to cure the patient nephrectomy must be done before the other kidney is involved.

6. The calculous kidney if untouched generally goes on to its destruction.

7. Pyelitis is the name of a condition that is rarely uncomplicated. It is often a transitional stage in pyonephrosis.

8. Ureteral calculi often lead to useless appendectomies.

9. The classical symptoms of vesical stone are more often due to tuberculosis or papilloma than to stone.

10. Vesical papillomata are potentially malignant but cystoscopically curable.

11. A large proportion of vesical carcinomata were initially papillomata that should have been removed then.

12. Palpation in renal disease is a fertile source of diagnostic error. The good kidney, with its compensatory hypertrophy, is more likely to be felt than the diseased one and just as likely to produce pain.

13. Pain is often as unreliable as palpation. It may be distant from the disease or upon the opposite side.

14. Middle lobe prostatic hypertrophy, though always obstructing, cannot be felt per rectum.

15. Vesical tabes gives all the symptoms and signs of prostatism in the absence of any obstruction at the vesical outlet.

Finally, few, if any of these things can be properly solved without the use of the cystoscope and its appliances and, as there is no community of size in which such conditions are not plentiful, there should be many more skilled systoscopists than there are today.

812 Medical Arts Building.

A Clinical Study of Ten Cases of Polycythemia Vera

LLOYD E. VERITY, M. B. (Tor.)
Battle Creek, Michigan

Polycythemia vera is a disease of unknown etiology, characterized by polycythemia, increased blood volume, and splenomegaly. Vaquez (1), of Paris, in 1892 was the first to describe a case of this sort, but his account did not receive much attention until Osler (2), in 1903, placed the disease as a new clinical entity. Since then several hundreds of cases have been reported.

In reviewing ten cases of erythremia treated at our clinic since 1912, I wish to review in detail one case which has been under careful observation for the past three years.

CASE.—Mr. C. G., aged fifty-one, had never been strong, always subject to weak and fainting spells and excessive perspiration. The family history was unimportant except for the fact that his father was of the phlethoric type, subject to fainting spells and excessive perspiration. The patient had been free from infectious diseases except for severe typhoid in 1899. Neither tobacco, tea, or coffee was ever used to excess.

His present illness began in 1918, when, following a tonsillectomy, he had a postoperative hemorrhage, which lasted several hours. Later the removal of two teeth was followed by an attack of nausea, excessive perspiration and dizziness, but no frank bleeding from the wound. A month after the removal of the teeth a complete physical examination revealed no important abnormality. The blood count was normal. Repeated kidney studies showed traces of albumin, but no casts, pus or blood cells. The Wassermann was negative. Throughout the following year he had occasional attacks of vertigo, fulness in head, perspiration, yawning, soreness, tingling and burning in the tips of the fingers and toes. He tired easily, had little ambition, and noticed an increasing nervousness and irritability.

In December, 1919, a complete general examination again showed no definite abnormality. Red blood cells were 5,120,000; the white cells, 8,400; hemoglobin, 86. A differential count gave polymorphonuclears, 76; lymphocytes, 12; large mononuclears, 5.6; transitionals, 1.6; eosinophiles, 3.2; basophiles, 1.6.

In April, 1920, his attacks of vertigo and headaches had increased in intensity and frequency. In May, he bled profusely following the removal of an abscessed tooth. Four weeks later a bloodvessel ruptured in the left popliteal space so the limb from the knee down was bluish black, swollen and extremely painful. In August, some two months later, the blood for the first time showed a marked polycythemia. The red blood cells had increased to 10,280,000, the white blood cells to 18,800, and the hemoglobin to 140. Blood pressure was 124 systolic, 80 diastolic, the differential count remaining normal. At this time the patient showed no evidence of cyanosis but presented a palpable spleen extending two inches below the costal margin. X ray treatment applied over the splenic area resulted in a slight drop in the red and white cell count and a reduction of the symptoms temporarily.

In December of the same year, x ray treatment was again applied to the spleen and the long bones, and this was followed by a reduction in count to red blood cells, 8,020,000; white blood cells, 14,000; hemoglobin, 95. The differential count showed a slight excess of polymorphonuclears and a reduction of the lymphocytes.

During the next three years the patient's condition remained practically the same. Below is a series of blood determinations which the patient, having kept accurate data, submitted to us. On two or three occasions during this time blood letting was done for the relief of distressing symptoms.

BLOOD COUNT

Date	Hemo.	Red cells	White cells	Neut.	Lymp.	L. Mono	Trans.	Eosino	Baso.
Dec. 12, 1919.....	86	5,120,000	8,400	76.0	12	5.6	1.6	3.2	1.6
Aug. 24, 1920.....	140	10,280,000	18,800	76.2	17	2.4	1.0	2.2	1.0

URANALYSIS:

Feb. 7, 1923: A. M.—Clear; amber; acid; sp. gr. 1.012: P. M.—sp. gr. 1.016. Trace albumin in both specimens; no sugar or bile; rare hyalin cast in both specimens; no blood pus, crystals; rare epithelial cell.

May 7, 1923: Cloudy; amber; acid; sp. gr. 1.018; trace albumin; no sugar or bile; rare hyalin cast; no pus, blood or crystals; few epithelial cells.

The patient consulted us in September, 1923, just three years after his original examination, complaining of a definite increase of his symptoms; i. e., headache, fullness in head, dizziness, excessive perspiration, tingling and numbness in hands and feet, and constipation.

The physical examination showed his nutrition to be poor; height, five feet ten inches; weight, 140 pounds. The skin was soft and flexible; lips and mucous membranes markedly congested and bluish in color; tongue large, red, and congested. The pupils were small and regular, reacting well to light and accommodation. The fundus examination showed a moderate arteriosclerosis with deeply injected vessels. There was some clubbing of the fingers. Examination of the chest, including radiograms, showed no evidence of any abnormality in the lungs. The heart was not enlarged, and the aorta was practically normal. A physical examination of the heart did not reveal anything abnormal. The liver extended one

inch below the right costal margin. The spleen came two inches below the left costal margin and was firm to the touch. Repeated Wassermann tests were negative.

A chemical examination of the blood, in terms of milligrams per 100 c. c., showed: nonprotein nitrogen, 35.2; uric acid, 4.9; urea, 11.3; creatinin, 2.3; blood sugar, 90; cholesterol, 100. The urine contained small amounts of albumin and negative microscopical findings. The blood count showed the following: red blood cells, 8,150,000; white blood cells, 23,700; hemoglobin, 105.

The differential examination gave: polymorphonuclears, 90; small lymphocytes, 1; transitionals, 2.5; eosinophiles, 4; mast cells, 1. Coagulation time was seven minutes. The red blood cells varied in size and shape, showing few poikilocytes and many myelocytes. Examinations of urine gave the following results: quantity, 35 to 40 oz.; reaction, acid; specific gravity 1.012; small amounts of albumin constantly present; no casts, pus or blood cells.

On October 22d therapeutic doses of x ray were given over the spleen and the ends of the long bones. Benzol, five minims in capsules, was given internally three times daily, starting with five minims for each dose, with an increase of one minim a day a dose, until fifteen minims at each time was reached. After six weeks the benzol was discontinued, as it had no apparent effect on the blood and the symptoms remained practically unchanged.

The cause of polycythemia is unknown. Richards and Herman (3) recognize three types: 1. that described by Vaquez and Osler, which shows a normal blood pressure and enlarged spleen; 2, a normal blood pressure but no palpable spleen; 3, the type described by Gaisböck, lacking a palpable spleen but showing a definite hypertension. In our series six cases belong to group 1, one case to group 2, and two cases to group 3. One case, showing hypertension with splenic enlargement, cannot be classified by this method of grouping.

The theories as to etiology are many. At the present time a number of writers consider that the disease is due to a primary irritation of the bone marrow. Examination of the blood in most instances shows evidence of marked activity on the part of the bone marrow, by the appearance of irregularities in the size and shape of the red cells, occasionally nucleated reds, the presence of myelocytes, and an absolute increase in the leucocytes, particularly the polymorphonuclears.

Pribam (4) believes the disease may be due to a lack of normal erythrocyte destruction on the part of the liver and the spleen or even in the blood itself. Bence (5) considers that polycythemia is due to a decreased capacity of the hemoglobin for oxygen. Rendu and Widal (6) think it is due to a primary tuberculosis of the spleen.

The disease is commonly seen during the years between fifty and seventy. The youngest of this series was thirty-six and the oldest sixty-eight. Men are much more frequently affected than women. In our series of ten cases, eight were men and two women.

Three characteristic signs of this disease are cyanosis, polycythemia, and splenomegaly. The cyanosis is not constant. Osler (7), in 1918, called attention to the fact that there may be considerable variation in the color of people, depending on the condition of the cutaneous vessels and the rate of blood flow. The reddish cyanotic appearance, which is usually seen in the face, hands, and feet, is apparently not directly associated with the increased red blood cells. In our series there was no relation between the depth of color of the extremities and the variation in blood count.

From a diagnostic viewpoint some of these patients show little or no cyanosis, and may even present pallor; so, unless a blood count is taken, such cases remain undiagnosed. In nine of our ten cases the cyanotic appearance of the skin and the mucous membranes was noted in the histories.

Christian (8) was the first to draw attention to the predominance of nervous symptoms which are often the cause of the patient's seeking medical advice. In eight of our cases neurological symptoms predominated, such as headache and fulness in head (eight cases), numbness and tingling of the extremities (three cases), paralysis (two cases), yawning (two cases) excessive perspiration (one case). Constipation is generally present. Other symptoms complained of are loss of weight, exhaustion, hemorrhages, indefinite pains in the epigastric and the left hypochondriac regions, and so on.

Splenomegaly is one of the important features of polycythemia. As a rule this enlargement is only moderate, but occasionally the spleen may extend beyond the umbilicus.

The basal metabolic rate was estimated in six cases, four ranging from plus 8 to plus 24; the other two cases were slightly minus, but within the normal variation. An increase has been reported as characteristic of erythremia, but, unlike the hyperthyroid cases, there is no corresponding increase in pulse rate or respiration.

The blood shows a persistent and absolute increase in the total number of erythrocytes, varying from six to 15,000,000. The highest count in our series was 11,050,000, with a hemoglobin of 100. Four months previously the same patient had a hemoglobin of 216 with a count of 10,160,000. There is usually a slight excess of hemoglobin present. The color index was usually less than 1. The leucocyte count was generally increased, and in one case it was found to be 29,000. The differential count showed a slight excess of the polymorphonuclear cells. The blood volume was increased above the normal. Coagulation time was normal. The viscosity was tested in one case by the method of W. R. Hess and gave a reading of 7.6, showing a marked increase above the normal. The fragility of the red cells was not tested. Freund and Rexford in a careful investigation report the fragility as normal, and the blood cells in normal and polycythemia patients are equally resistant to hemolysis.

An ophthalmoscopic examination was made in five cases, four of which showed constant changes, dark colored dilated retinal veins. One case had marked tortuosity of retinal vessels.

Postmortem findings reported by various authors have revealed an extreme distention of all the minute vessels with blood. The medium sized arteries show moderate sclerosis. There is generally some hypertrophy of the left ventricle. The spleen shows enlargement without any marked pathological change

The splenic pulp is increased, and in some cases the trabeculæ and septa are thickened. The most marked change occurs in the long bones, which have a uniformly dark purple appearance, which under the microscope shows signs of extensive activity.

Gorham and Myers (9) stated that normally the concentration of cholesterol is nearly the same in the plasma and the whole blood although if anything the plasma content is slightly high, and pathologically it seems to be subject to somewhat greater variation, the normal value being 0.16 to 0.17 per cent. with a variation ranging from 0.13 to 0.19 per cent. Rothschild and Telsen considered that the liver is the regulator of cholesterol metabolism of the body, the cholesterol being kept at a more or less constant level by excretion of cholesterol through the bile.

W. Denis (10) noted subnormal values in primary and secondary anemia, but was unable to find any definite relation between the number of corpuscles or hemoglobin percentage and the cholesterol value in such cases. Pribam (11), who also found high values for cholesterol, believes that in erythremia the high cholesterol content in the serum prevents destruction of the red blood cells by the spleen. Lowry (12) corroborates these findings, and his conclusion is that increased serum cholesterol prevents red blood cell destruction and the piling up of old red cells in the blood stream acts as a stimulus to the blood forming marrow with a consequent appearance of immature red cells.

Richards and Herman (13) report a case of polycythemia with a blood cholesterol of 0.312 per cent. The cholesterol content of the blood was estimated in two of our cases. In these our findings do not agree with the authors above mentioned. In one the cholesterol was distinctly subnormal, while the other was within the normal range, 0.100 per cent. and 0.140 per cent.

Erickson (14) and others have reported an increase in the blood uric acid in polycythemia vera. Isaacs (15) reports a case with a uric acid estimation of 6.9 mg. and three months later 8.59 mg. He concludes that, in the absence of renal involvement, the increased uric acid may have its origin in the liberated nuclear material in the increased production of red cells, from the extrusion or dissolution of the nuclear material of the normoblasts at their place of origin.

Loeper and Marchal (16) compare five cases of polycythemia in which digestive disturbances dominated the clinical picture. The symptoms in some cases simulated gastric ulcer. They concluded that every dyspeptic inclined to phlethora should always have a blood count taken and the viscosity measured.

TREATMENT

The etiology remaining obscure, our treatment of the disease is necessarily empirical. We have, however, several therapeutic measures which give symptomatic relief.

1. *Venesection* produces temporary symptomatic relief but no permanent benefit. If we consider the disease to be due to a primary hyperplasia of the erythroblastic and the leucopoietic tissues of the bone marrow, then our treatment must be directed at the source with a view to inhibiting the formation of the erythrocytes. We have some evidence that the spleen is destructive in its action, destroying the red cells by the phagocytic action of the cells of the spleen. If this splenomegaly, then, is wholly compensatory, therapeutic x ray treatment should be given in stimulating doses.

2. *Rays.*—Stengel (17), in 1917, was the first to treat polycythemia by applying x ray therapy to the long bones. We agree with Bothner (18), Pendergrass (19), and Krumbhaar (20) that radium therapy should be directed first to the terminal ends of the long bones, in destructive doses, in an effort to prevent erythropoietic production; second, in stimulating doses to the spleen to promote erythrolysis.

3. *Splenectomy.*—Several writers have reported temporary favorable results by splenectomy, while others hold it to be contraindicated. W. J. Mayo, (21) recently mentions a case in which splenectomy was performed with relief of all symptoms for a period of two years. The red cells remained around 6,000,000 and the hemoglobin higher than normal. The relatively few cases reported in the literature do not permit further comment.

4. *Medication.*—At the present time we have discarded all drugs with the exception of benzol. The use of benzol was suggested by Selling (22) and afterwards made practical by Von Karany (23). McLester (24) reports cases treated by benzol which showed complete, although temporary amelioration of all symptoms. Other observers do not report the same results. It is now generally conceded that benzol combined with x ray or radium gives the best results. In three of our cases stimulating doses of x ray to the spleen were given with destructive doses to the ends of all the long bones while five minims of benzol were given three times daily, increasing one minim each day until fifteen were taken and then continued for one month. The results in two cases were good, but the third failed to respond.

This résumé is given in an effort to correlate the clinical evidence in ten cases of polycythemia which appear to us as interesting.

Renal Infection*

JOHN H. CUNNINGHAM, M.D.
Boston

Renal infection is one of the commonest diseases with which the urologist has to deal. It is a condition that he is most concerned about avoiding; one which he constantly has to treat, and is the disease which is accountable for most of the deaths occurring in connection with any of the diseases of the genitourinary system.

The route of invasion in renal infections has generally been accepted as being by way of the blood stream, yet there are instances most difficult to explain on this ground, and which from all clinical and even theoretical considerations, suggest that ascending infection has occurred. Because of such suggestive clinical evidence, and because of the inconclusive data concerning the ascent of infection along the ureter, one of my associates, Dr. Roger C. Graves, engaged in an extensive investigation of the problem, while in charge of the Surgical Research Laboratory of the Harvard Medical School. A portion of this work has been published recently (1), and will be briefly outlined at this time.

There are three conceivable possibilities in the ascent of infection from the bladder to the kidney along the path of the ureter.

1. Lymphatic extension through the ureteral wall. Anatomy denies this route because there is no continuous lymph stream between bladder and kidney. Furthermore, experimental work has failed to conclusively demonstrate such a path of ascending disease.

2. The extension of infection along the lumen of the ureter, through, and against the column of descending urine in the presence of disease of the intravesical segment, so that the bladder and kidney pelvis are in open communication. This passive ascent needs no further comment, and occurs only in advanced stages of urinary tract pathology.

3. Extension of infection along the lumen of the intact ureter, in which bacteria are carried upward through the force of bladder regurgitation.

Beginning with Semblinow in 1883, it has been repeatedly demonstrated in the laboratory that regurgitation of vesical contents may be produced in normal animals. Moreover, in 1916, Kretschmer, in a series of cystograms in individuals without urinary tract disease, found in some instances that a reflux of the opaque solution into the ureters was revealed in his x ray plates. In spite of these important observations, no work has been done to determine accurately the factors which produce this phenomenon, and the conditions under which it occurs. With the purpose to answer these questions, the research of Dr. Graves was undertaken.

Experimental methods consisted, briefly, in slowly filling the bladders of normal rabbits with body warm physiological salt solution, through a catheter tied within the urethra. The animals were anesthetized with urethane, which gives analgesia but does not interfere with the tone of smooth muscle. The experiments were performed within a thermostat chamber maintained at body temperature, and an abdominal incision, in most instances, made possible the exposure to view of the urinary organs. A mercury manometer in communication with the filling system, recorded intravesical pressure. The physiological saline solution used in filling was colored with small amounts of methylene blue for the purpose of increased visibility. Bladder distention was not carried beyond physiological limits, and excessive pressures were not engendered.

In the first series seventy-five male rabbits were studied by this method, and an effort was made to simulate as closely as possible normal vesical distention. Regurgitation of vesical contents into the ureter was observed in 73.7 per cent. of the cases, and in the second half of the series, with a more established technic, reflux occurred in 86.8 per cent. of the cases.

A typical experiment has been reported as follows:

At the beginning of the bladder filling both ureters presented vigorous peristalsis. When ten c. c. had been introduced the ureters were still active, and the bladder was resisting distention actively, as shown by its tense cylindrical form. Pressure: five mm. mercury. With twenty c. c. the pressure was nine mm. mercury; the bladder was quiet, and both ureters were active; twenty-six c. c.: a sudden rush of a blue column of fluid was observed pouring from the bladder into the left ureter, and filling its lumen to the kidney. Similar regurgitation soon followed on the right side. Pressure: eighteen mm. mercury.

All possible sources of error in these observations were carefully controlled. For example: many types of anesthesia were used, and in many instances the abdominal wall was left entirely intact until the close of the experiment.

A study of the results of this socalled normal series revealed the fact that two types of bladders were encountered. In some of the cases the bladders filled passively, with no resistance to distention. In these toneless bladders the pressure finally engendered was purely mechanical tension, produced because the sac could hold no more. In such instances regurgitation never occurred. In other cases, however, the bladder with relatively small amounts of fluid, actively resisted distention, with tonic contraction of the vesical musculature, and in these cases, with the active pressure thus produced, reflux was usually obtained. The one fundamental requisite, therefore, of this phenomenon, would appear to be active tone of the bladder musculature.

In the second series, the experiments were performed upon thirty-eight rabbits whose ureters had been disturbed in previous operations. In some of these animals the ureters had been completely obstructed; in others, partial obstruction was accomplished with aluminum bands; in still others the ureters had been doubly tied and cut across; and in five cases the kidney and ureter had been dissected free from all nerve and blood supply down to the

*Summary of Dr. Cunningham's paper on Renal Infection, read before the Section in Urology of the New York Academy of Medicine.

bladder wall itself. Inasmuch as there were no essential differences in the production of regurgitation under these conditions, it was concluded that the degree of ureteral activity had little bearing upon the phenomenon. This is in sharp contrast to the beliefs of earlier workers, who were inclined to ascribe reflux to peristaltic or antiperistaltic ureteral contractions. It should be noted that in this work antiperistalsis was never observed, and has no part, therefore, in the problem of regurgitation.

In another series the experiments were performed upon normal intact unanesthetized animals, observations being made possible by the fluoroscope. In these cases sodium bromide solution was used for bladder filling. Six of the eleven animals studied by this method showed regurgitation under the fluoroscope, and x ray plates were taken for permanent record.

From the foregoing evidence it may be concluded that regurgitation of vesical contents into the ureter may be accepted as an experimental fact, and as a clinical probability, and that it may be held accountable for ascending renal infection, particularly in cases of vesical neck obstruction. Further experimental and clinical reports are to be made.

The following clinical observation is one which we have frequently noted, and I have no doubt is also familiar to all present. A person whose ureteral orifices have been previously determined to be normal by cystoscopy, has a suprapubic prostatectomy performed. The convalescence has been uneventful, and the temperature has been normal. The suprapubic drainage tube has been removed, and just at the time when the sinus closes, and before the normal act of urination has been well established, there occurs a chill, followed by a sudden sharp rise in temperature, and the usual symptoms and signs appear, which we recognize as renal infection, and commonly call pyelitis. In this situation under discussion there has been no change in the condition or treatment of the patient prior to this phenomena, and no new areas for absorption have been produced by instrumentation, or in other ways, which might make probable a blood stream infection. We believe that this picture is one of ascending infection, and that it can only be reasonably explained on the basis of ureteral regurgitation.

This clinical picture not only occurs in the postoperative course of prostatic patients, as discussed above, but the regurgitation of infected urine may also take place and give rise to the same clinical phenomena during bladder drainage, with an indwelling catheter which becomes temporarily blocked. I believe, as we refresh our recollections, that we can all recall patients who have been doing well under catheter drainage, in whom suddenly, and for no apparent reason, there develops the familiar sequence of chill, fever, and pain in the region of the kidney. The onset of the renal infection has been evident enough, but its manner of production has not always been so readily explained, as there seems no reason that such a sequence of events should be brought about by a blood stream invasion by organisms. Often in these cases close questioning will elicit the fact that prior to the chill the patient has experienced a sense of bladder distention, produced because the catheter has ceased to drain. Under these circumstances the catheter has become an obstruction to the outflow of infected urine from the bladder, and has produced a spasm of bladder musculature, and a consequent reflux of infected urine up the ureter to the kidney.

In addition to the occurrence of ureteral reflux and renal infection under conditions which we have described, regurgitation of infected urine must be considered a factor of great importance in producing renal infection, even before any form of treatment is instituted, and may be accepted as an explanation of renal infection associated with vesical neck obstruction in patients whose ureteral orifices appear normal by cystoscopic examination.

While emphasis has been placed on the possibility of renal infection from regurgitation of bladder contents, it is not our feeling that this is the commonest route of kidney invasion. We still feel that the majority of cases are of hematogenous origin. By whatever path the kidney is infected, whether through ureteral regurgitation, or through the blood stream, the picture varies in degree from a mild pyelitis or pyelonephritis, to those more advanced conditions involving much kidney tissue, and even extensive renal destruction.

That hematogenous infection of the kidney must be considered the most common is, as has been said, not questioned. The differentiation from the ascending type is usually difficult. The absence of any vesical neck obstruction and the presence of any septic foci demonstrable anywhere in the body, naturally leads to a belief that any particular instance is due to organisms gaining entrance to the blood stream, and reaching the kidney by this path. The absence of positive bacterial findings in blood cultures in such cases does not preclude this avenue of invasion. It is interesting to note in this connection that organisms may be recovered from the blood stream during the period of the rigor associated with the onset of the disease, and following this be absent from the blood, which makes it probable that the rigor is an expression of the blood stream invasion as in some other diseases, such as malaria.

We now classify renal infections into three groups, based on the pathological findings and clinical signs. The *first* group, the most severe, is the infection of hematogenous origin which produces multiple foci of suppurative processes throughout the kidney, and which results clinically in a progressive toxemia, which may become profound and result in death. This is the form of disease originally described by Brewer. It is the fulminating type of renal infection, which is frequently confused with intraabdominal inflammations, such as acute infection of the gallbladder, ruptured duodenal ulcer, and acute appendicitis. This group of patients is more apt to be observed by the general surgeon than the urologist, because the disease produces acute abdominal signs. The urine is essentially negative, and the patient gives the general clinical picture of intraperitoneal sepsis. The only clinical sign differentiating the disease from intraabdominal lesions is costovertebral tenderness and spasm of the lumbar muscle.

I have observed thirteen patients with this form of the disease, who were subjected to nephrectomy, and two who were treated by decapsulation, together with drainage of the renal pelvis in one instance.

The thirteen patients in whom nephrectomy was performed recovered, and the two in which the less radical operation was carried out, died. It is felt that this type of the disease which produces progressive, profound toxemia, will result in death in the great majority of cases, provided the body is not rid of the severely infected kidney.

The *second* type of the disease is a diffuse, nonsuppurative inflammation, a type of infection which spreads through the kidney substance, but does not result in focal abscesses and solution of tissue. The clinical picture produced by this more common, nonsuppurative infectious nephritis differs from that with abscess formation chiefly in the severity of the symptoms. The onset may be sudden, as in the former type, the temperature rising rapidly to 102° or more, associated with acceleration of the pulse rate; and a leucocytosis is always present, often high. A chill may accompany the onset. Pain in the loin is an early symptom, sometimes indefinite, but often severe, varying according to the severity of the process. Tenderness over the kidney in the costovertebral angle with some muscular rigidity, and abdominal tenderness and rigidity on the affected side, are constant signs. The chief feature differentiating this form of the disease from that of abscess formation is the lack of progressive toxemia, and the presence of more abnormal elements in the urine. These patients, while appearing acutely ill, do not have the progressive toxic course which characterizes the first described form of the infection. The fever after the first few days following the onset may gradually subside, if the process is not very extensive, or remain more or less stationary, and may continue not unlike a beginning typhoid. Pain on the affected side may persist indefinitely, and recurrences of the acute symptoms are not uncommon. In the severer forms of this type of the disease, operative procedures in the form of decapsulation, puncture, and drainage of infected areas, have been of value in shortening the course of the illness, and giving relief from pain, particularly in the cases where persistent infection remains over a period of months, and a contracted scar in the renal tissue is the cause of the constant discomfort. I have operated upon eighteen patients of this group.

The *third* group is a milder manifestation of the nonsuppurative inflammatory process. The symptoms, following the acute onset, subside more rapidly, often assuming a more or less chronic form almost from the beginning. It is these relatively mild infections which we, as urologists, commonly deal with, and which are amenable to milder measures, such as forced fluids, urinary antiseptics, free catharsis, and in the more obstinate cases, lavage of the renal pelvis.

In conclusion, I submit that renal infections, of paramount importance to the urologist, can no longer be considered as solely of hematogenous origin. Regurgitation of the bladder contents in the presence of vesical neck obstruction has been shown to make possible an invasion of the kidney through the ureter from the lower portions of the urinary tract. The pathological processes produced by infection, ascending or hemic, may be in all gradations from simple to most diffuse, and even suppurative forms.

Treatment, as always, must be measured in terms of the disease, and varies from radical surgical intervention to the mildest therapeutic measures. Finally, wherever a nidus of infection can be discovered in tonsils, teeth, or other organs, it is of primary importance to determine such a focus and destroy it; a matter too often disregarded. Moreover, it is fundamental that the obstruction to free drainage, which has produced stasis and lowered resistance within the urinary tract, should be eradicated, for without the relief of causative factors, any form of treatment may be of little permanent avail.

(*Concluded from page* 266)

According to Bolk, the cerebellum is divided into an anterior and posterior lobe by the *sulcus primarius* which corresponds to the *fissura prima* of Smith. The anterior lobe is divided by a series of three fissures into four lobules which Bolk numbers 1, 2, 3, and 4. A small and shallow fissure parallel to the *sulcus primarius* delimits the *lobulus simplex* which extends from the vermis out upon the lateral expansion of the hemispheres. The major portion of the posterior lobe, however, that which lies caudal to the *lobulus simplex,* is divided into a median lobule and two lateral lobules. The median lobule constitutes the vermis and is separated from the lateral lobules by the two *sulci paramedian* one of which lies on either side of the vermis. The vermis itself is divided into four lobules, respectively indicated as C-2 and C-1, B and A. The fissura secunda passes between C-1 and B. The lateral lobules are divided into two main portions, the *lobulus ansiformis* and the *formatio vermicularis.* These are separated by a deep incisure, the largest fissure in the cerebellum, the *fissura paraflocculа.* The *lobulus ansiformis* is divided by a transverse fissure the *sulcus intercruralis,* into Crus I and Crus II. Where the *lobulus ansiformis* and the formatio vermicularis come into relation with the posterio

*Illustrated talk to New York Neurological Society, February 6, 1923.

nedian lobule, there is a portion of the cerebellum which Bolk defines as the *lobulus paramedianus*. He xplains the striking variations of the cerebellum on he grounds that form is dependent upon function nd there must, therefore, be some direct functional elationship between these variations in the cere-ellum and the control of the muscular system whose onic, sthenic and static activities are dependent upon his organ. He concluded that all of the muscles of he body may be divided into two groups: those which act bilaterally together, such as the trunk nuscles, and those which, although bilaterally pres-nt, have a certain independence in their activity ke the muscles of the arms and legs. The muscle roups which show this independence of action are nilaterally synergic, while those which depend upon simultaneous coordination are bilaterally synergic. o the latter group belong the muscles which pro-uce movements of the head, of the eyes, of the nouth and jaws, of the tongue, pharynx and larynx, nd of the trunk, in addition to certain movements f the upper and lower extremities which require ilateral innervation and act together as in loco-notion. Upon the hypothesis, Bolk based his local-zation in the cerebellum of control for the two ma-or groups of muscles. The cerebellar cortex is omposed in mammals of a number of coordinating enters, some of which are paired for bilateral syner-ic control, while some are unpaired for unilateral ynergic control.

"The *lobulus anterior cerebelli* contains the coor-inating centers for the muscles which are active in novements of the head. The most anterior lobule s for the eyes; the second lobule, for the tongue; ne third, for the muscles of mastication, and the ourth, for the muscles of expression and of the me side. The remainder of the cerebellum contains ne paired synergic centers for the muscles of the eck. In the upper portion of the *lobulus medianus* osterior are the paired centers for movements of ie right and left extremities. The *lobuli ansiformes* nd *paramediani* contain unpaired centers for the xtremities, the arrangement of the centers in each ase being ipsilateral, Crus I corresponding to the rm of the same side and Crus II to the leg of the me side. The remainder of the cerebelli contains oordinating centers for the trunk and the tail re-ion, the formation vermicularis particularly having ontrol of the tail.

"This localization in the cerebellum by Bolk on the rounds of comparative anatomy was subsequently onfirmed by André-Thomas and Durupt and by an Rynberk through many experiments upon ani-als."

Bolk is preeminently an anatomist and I can with ropriety leave him with but little mention of his any valuable anatomical researches, to take up a gure identified with neuropsychiatry in Holland for any years, Jelgersma, professor of psychiatry in ie University of Leyden. I met Jelgersma about 905-1906 and as he brought to my attention first work which has been one of the most enduring elights of my library, I owe him an early debt of ratitude. It is that remarkable classic by Jules oury on the History and Development of the Doc-ines concerning the Nervous System and its Func-tions, a work, for a neurologist not to be acquainted with is to drop out Hamlet from the play. When in 1910 I had the pleasure of meeting Soury in Paris it was a delight as striking as had been that on reading his book. It was from Soury that an interest in Leibnitz arose and you now know the history of a not infrequent remark made by me in this society, for Leibnitz in a foot note on the first page of his *Monadology* says "he reads a book not for what he could find to criticize in it but for what he could find new."

Jelgersma's work has been very extensive. Concerning some of the phases of modern neurology it may be recorded that Jelgersma (12) in 1908 started our modern researches upon the pathology of the striatum and its connection with paralysis agitans. He had noted in paralysis agitans marked atrophy of the lenticular fibres on their tweenbrain pathways. The reduction of the ansa lenticularis and ansa peduncularis, of the H_1 and H_2 fields of Forel, the lateral thalamic nuclei, corpus Luysii, and the radiations of the substantia reticularis. The red nucleus and pontine structures were not modified. Whereas the interpretations of the present time have moved beyond their early formulations it is to Jelgersma's credit that he noted the striatal fibre system alterations. The paralysis agitans problem is still unsolved even though our own genial Ramsay Hunt has cast some highly valuable light on certain aspects of the problem to which Lewy (13) and Bielschowsky have added their observations.

Jelgersma's contributions to the function of the cerebellum have been of marked value (14), especially in their phyletic relationships since he has made extensive investigations of cerebellar function in Cetaceans. Jelgersma has emphasized the opinion that the cerebellum has no relationship with the vegetative organs. In the innervation of the blood vessels, the smooth muscle tissue, the endocrine organs the cerebellum plays no part and he states that no connections with the sympathetic system are known. It also has no relation to smell, sight, taste or hearing. Only two feeling qualities he maintains are localizable in the cerebellum. These are deep sensibility of muscle and joint, and secondly tonus and equilibrium. Whether this position can be maintained in view of growing views implicating the sympathetic system as essential components in muscle tonus I for myself am still in doubt.

Jelgersma has given a masterly textbook on psychiatry. Written as it is in Dutch it is little known but it will repay careful study. Finally it may be added that Jelgersma has developed a strong supporter of the psychonalytical theories, which in passing it may be stated is shared by many of the younger Dutch neuropsychiaters, among whom a strong psychoanalytical group has developed.

I have already spoken of the foundation of the Central Institute for Brain Research and the appointment of Dr. C. J. Ariëns Kappers, one of Winkler's pupils as its Director. Still a young man, Ariëns Kappers has done a prodigious amount of work on the comparative anatomy of the nervous system. Even to read a mere list of his researches

would consume a whole evening. These have been most aptly and beautifully gathered together now in three large octavo volumes. The first by Droogelever Fortuyn on the Comparative Anatomy of the Invertebrates and two others by Kappers on the Comparative Anatomy of the Nervous System of Vertebrates. I have analyzed these elsewhere (Book Review, *Journal of Nervous and Mental Disease*) and many of you are acquainted with more than the title page which is here shown. Here as with Winkler, as we may gain from a short glimpse of his "Introduction," we note that Kappers follows the same note of an organizing synthesis function of the nervous system in its handling of cosmic stimuli. The naïve conception of the steamboiler-man whose stomach alone provides him with energy has little place in modern energetic conceptions of the nervous system. The "calorie" concept is too narrow for the "organism as a whole" in its highest sociotropic activities.

Humoral pathology is comparatively a dead letter for anything beyond protozoa or coelenterates. Pathology, in the sense of disturbance of a *neurally integrated mechanism,* has become the order of the day, even in some recent discussions of the mechanism of inflammation. Immunity, anaphylaxis and other concepts lack precision until they are founded upon a neural more than upon a humoral basis. But this is an aside save by implication as one of the major premises of Kappers' work. A second premise I might touch upon in my hasty review. This concerns itself with the development of a concept of structural evolution going on within the nervous system to which Kappers has given the name of neurobiotaxis and to which he has contributed a dozen or more studies. How have nervous structures come to arrange themselves as they have in the gradually increasing complexity of the animal phylum? This has been a question. Chemotactic theories relative to the positions of axon and dendrites were among the earlier types of solution before comparative structural facts were available. As these accumulated it was seen that displacements of ganglion cells and their groupings were very striking.

The chemotactic hypothesis (Cajal) does not seem to cover the situations and Ariëns Kappers made use of a term neurobiotaxis to envisage his newer concept. The process of displacement, as for instance of the cranial nerve nuclei in their phyletic series is not explicable, he shows, on plasmodesmic or chemical "forepath" hypotheses. One must pay more attention to the origin of the stimulus. Kapper's illustrations most convincingly show the gradual shifting of the oculomotor, trochlearis, trigeminus, abducens, facialis, glossopharyngeus, vagus, accessorius and hypoglossal nuclei. This shifting has taken place as the animals have evolved variations in ways of varrying on their biological functions.

The details can not be entered into here (15). I can only report upon his conclusions, namely that the neurobiotaxic phenomena are explicable only on the basis of ideas which have come to be formulated relative to psychological conceptions. In other words, as with Gaskell, who it will be recalled said that "from below up we can only guess, from above down we can interpret," so Kappers states that the psychological, i. e. advantage of the whole animal as a unit in his adjustment to his environment [head end stimulus] follows psychological laws. This is another way of saying that function is primary structure secondary. They are coordinates, but the structure can be made to change in view of the *wish* or the *need.*

My time is up and I regret that I must leave you at this point with but a partial glimpse into the entrance gateway leading into many pathways of interesting research in this small but productive country. I have only time simply to mention a few of the active workers, many of whom have given enduring contributions to the special field of our interests. A discussion of Brouwer's work could easily occupy an evening. As clinician, anatomist, pathologist and teacher he occupies a unique position and well merited his election to the chair of neurology so honorably filled by Salomonson. Psychiatry as represented by the Boumanns, of the same name but not related, is being actively advanced and from the various institutions scattered throughout Holland, masterly scientific papers are being produced. The work of the Boltons on the vegetative nervous system is also worth a word, but I must stop, rather abruptly, with the hope that I may at some future meeting supplement this introduction by a more even presentation.

Heterotopia of Central Nervous System in Relation to Malformation of Body Segments and Nervous Diseases

HENRY WINSOR, M.D.,

Haverford, Pa.

This paper is one of a series in which attention is called to evidence for the opinion that disease is a feature of evolution as well as due to the effects of environment; also, where, why and how lowered resistance, susceptibilities or vulnerabilities arise.

The data consist partly of citations from acknowledged founders of evolutionary and medical science, partly from a survey of much pathological material and in particular of certain personal experiments which go to sustain the opinion that disease is an important factor in evolution.

I would postulate that: In a full survey of the phenomena of evolution of species it will be found that a full consideration of certain anomalies of structures and deviations of growth forces in certain individuals offers a valuable—perhaps the best—explanation of phases of the evolution of disease.

Genetic problems deserve to be approached from at least two angles: a, from the centres of origin or manifestations of growth forces outward as they evolve, as well as: b, from phenomena as they are observed in relation to the centres, that is, from the periphery backward.

The query is submitted: Have these manifestations been studied sufficiently from the central approach? May not a study from the centres outward supply as much, possibly more of significance, and many facts not as yet appreciated?

Is not this approach from the centres of origin also more economic, more accurate, more sequential from cause to effect, and of greater practical utility as to possible prevention or remediation? A combination of approaches from both angles is doubtless best.

Meanwhile I present the evidence we have collected from this central avenue. This evidence consists of both a pretty thorough survey of the literature in the form of exact citations of such facts, observations, inferences, as are to be found in the writings of such men as Darwin, A. R. Wallace, Geoffrey St. Hilaire, Haeckel, Joseph Leidy, Serres, Codvilla, Boujard, and others, among which many highly significant and illuminating remarks are found. Many of these seem heretofore to have been overlooked, disregarded, or erroneously interpreted. These views are also found to have been accepted, endorsed, or amplified by later writers of highest authority.

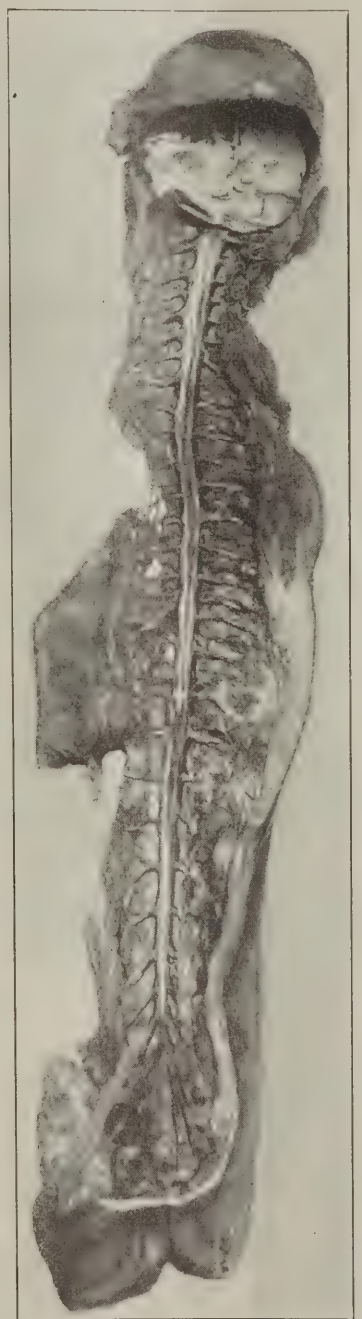

Fig. 1.—Photograph by Mr. Erwin Faber of personal dissection made by the author when prosector to Professor Piersol, in the Anatomical Department of the University of Pennsylvania, from a frozen formalin specimen chosen for its normality.

These citations we have arranged in orderly or correlated associations forming a fabric of evidence which at least deserves open minded consideration, and also: (in a later contribution with original illustrations) personal studies by me on full transections of the spinal column in embryos, bones and all. These were later decalcified and studied in accord with their original relationships. This, by the way, has not been the course pursued by the more modern students of the cord and its structure. The cord is generally removed from the bones whereby the anatomical associations are altered or lost.

Anatomical material, partly such as handled by myself and also many careful observations made on specimens presented in collections and in museums, as well as observations of skeletons in museums both modern and ancient, will be presented.

This material is of both human beings and also animals, not alone of today but also ancient, some being prehistoric. The mass of these observations is growing surprisingly. They can only be ignored by those who decline to make similar or independent observations from equally reputable sources.

Particular attention is urged upon the plan pursued of studying cross sections of the entire spinal column, bones, bloodvessels, cord, etc., thus preserving the full associations, relationships, adaptations.

Only by pursuing this plan of studying phenomena in their exact, undisturbed correlationships, is it possible to note significances as they emerge and group themselves. Only by a careful survey of the earlier literature, by giving due weight to many cautious statements and inferences can a symmetrical impression be formed. Only by pursuing the same plan can the inferences reached be disallowed or disproved.

The central canal of the cord, and a portion of it prolonged into the brain, may be regarded as originally a segment of intestine now disused for alimentary purposes and undergone gradual transformation into a spinal canal, rendering certain structures vestigial which not infrequently behave in a manner pernicious to the individual (1). The great factor in evolution has been throughout the growth of the central nervous system (2). This germ band from which the whole embryo grows, corresponds exactly to the position of the central nervous system (3). Of individuality in organisms, and of axial gradients, the relation of the central nervous system to these gradients is highly significant. Each organ or part arises in relation to one or more of these gradients (4).

The spirem is seen in the karyokinesis of all cells (5). Of the spiral, Swedenborg says, "It is capable of transformation into infinite forms, of adapting itself to every space, and hence this form derives the power of infinite variation (6). We are able to trace the mutability of individuals to the mechanical conditions of nutrition (7). The spiral type of organism owes its peculiarities entirely to mechanical conditions (8). In regard to comparison of SGR variations in humans with those of beasts, we must absolutely concede that the lowest forms (which show a tendency to curve or spiral formation) possess models in beasts, therefore the variations are in phylogenetic age direction (9).

Fig. 2.—Photograph by Mr. Erwin Faber of a transection of a frozen formalin head in the anatomical department of the University of Pennsylvania. Asymmetry of brain.

In amphioxus, (lancelet), the region of extreme torsion is around the mouth; in the posterior part of the pharynx, the parts appear and remain in normal position; during later development it becomes corrected by a compensatory growth of the pharyngeal structures in the opposite direction (10). In man, Falk describes, curvatures and malformations of the cranium (11). In a number of fishes, the want of bilateral symmetry is very striking; the body is very compressed, and on one side, is whitish or uncolored, while the other is dark; further, the eyes are both on the colored side. When they are born, they are symmetrical, with an eye on each side, and may be seen swimming in midwater, nearly straight, but with a tendency to lean to one side. The tendency to do so becomes more marked; but the eye of the inclined side disdains to look downwards, and strives to look upwards; the endeavor accomplishes its purpose, and finally it becomes settled upwards, and the contiguous parts of the skull are twisted round to correspond (12).

The skull develops in precisely the same way as the vertebral column. The right and left head plates arch towards each other over the brain bladder, enclose the anterior extremity of the chorda, and thus eventually form a simple soft membraneous capsule around the brain (13). For, we must differentiate three stages in the development of the vertebral column, membranous, cartilaginous and bony (14). It is not known how far the olfactory and optic nerves, which originate from the precordial brain, agree with spinal nerves, but all the other cranial nerves are entirely segmental (15). Abnormalities and deformities of the skull capsule will always be of the greatest importance (16).

When the neural folds are nearly closed, a slow rotation of the embryo about its horizontal axis begins; so that in the course of a few hours the embryo lies on its side and often on its back. Later it rotates constantly about a vertical or oblique axis. Such rotation of amphibian embryos has been noted by Clark, Eyedeshymer, Assheton and Wilson (17). In chick embyros, between the forty-eighth and fifty-fifth hours, the embryo quits the right position which it has had up to this time; it bends itself and inclines constantly to the left side (18). It is this inversion of position which effects the inversion of the vessels. For, in the plan above the umbilicus, the veins are anterior and the arteries are posterior: in the plan below (the umbilicus), the arteries are in advance and the veins behind (19).

In pigeons, the tumblers have the strange habit of ascending into the air in great numbers, then turning over and falling down through the air as if dead (20). Near Glasgow, there are house tumblers, as I hear from Mr. Brent, which cannot fly eighteen

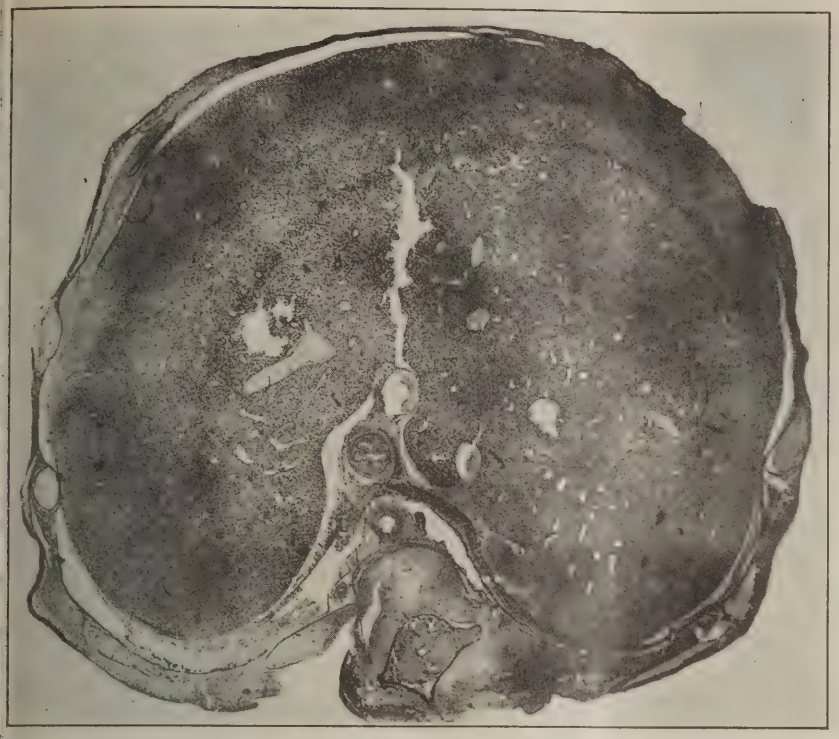

FIG. 3.—Malformation of a human embryo from embedding in the tube of an ectopic gestation. Embryo removed by the late Professor G. G. Davis. The patient recovered. Photograph by Mr. Erwin Faber.

inches high without going head over heels (21). All pigeons without exception must have been derived from the blue rock (C. Livida) (22). Pricking the base of the brain and giving hydrocyanic acid, together with strychnine, to an ordinary pigeon, brings on convulsive movements, exactly like those of a tumbler (23). Of Lotans or Lowtans, a variety of roller or tumbler, "When required to tumble, they are taken in the hand, the head slightly rubbed or filliped with the finger, and then they are put on the ground, where they continue to tumble till taken up (24).

The back somersaults that rollers throw in the air is the chief characteristic of this variety and subvarieties of pigeons. It is also undoubtedly a disease. Man selects knowingly, with an object. Nature eliminates blindly, without an object (25). Man has selected diseased tumbling pigeons, until they became a variety with subvarieties. Nature would have eliminated by hawks, scavengers which remove the weakest of the flock, had not man bred from the tumblers alone. Darwin mentions the preservation of a large number of individuals which varied in any favorable direction, and the destruction of a large number which varied in an opposite direction (26). Before it was perceived that disease is an undisputable battleground of the true Darwinian struggle for existence, the tremendous part which it takes in ridding the earth of weaklings and causing the survival of health was all credited to the environment and its dead physical forces (27). When variations, which we call disease, occur we are learning to look for the point of departure from the normal environment (28). Therefore the nonadaptive variation is the disease, and parasites are secondary to it. Every step in evolution from invertebrate creature to vertebrate fish, birds, beasts and men, has been paralleled within them by different kinds of infesting parasites (29). The decisive factor that runs through every struggle, wherein other factors are equal is disease. The survivors are those who have become modified to resist strain (30) (of bacteria, etc.). In the case of the roller or tumbler, man has selected diseased, i. e., tumbling pigeons until a new variety with subvarieties, has been established as entities.

The Rôle of Selection

Selection by nature is in the abstract, the concrete is elimination of the nonadaptive variants by microorganisms. In the evolution of species, the nonadaptive variants die from disease, and there is no difference between the evolution of species and

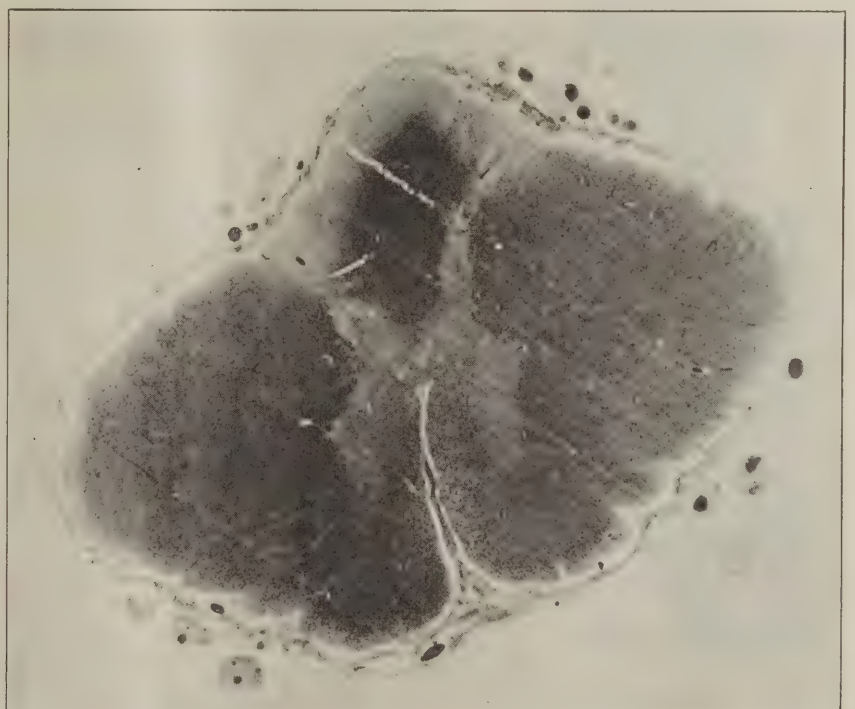

FIG. 4.—Published through the courtesy of Krumbhaar and Winkleman. Lesions of multiple sclerosis accompanying extraordinary bilateral asymmetries of the spinal cord.

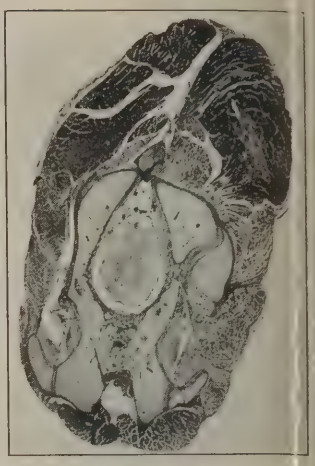

FIG. 7.—Clockwise rotation. Oblique section, though nearly mesial, of clockwise or right rotation of neck of squab.

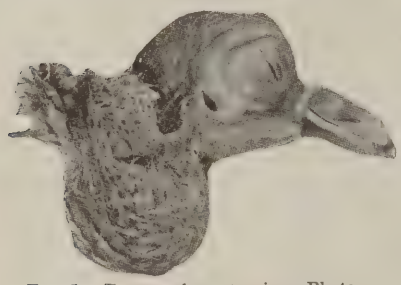

FIG. 5.—Extreme hypertension. Photographs by Mr. Gosner, mesial section by Miss Brown, permission of Dr. Krumbhaar. Flexion of the spinal cord due to flexion of the vertebral column.

the evolution of disease.[1] The one being the corollary or supplement of the other. For anomalies are equivalent to true diseases by the pernicious influence which they exercise on the organization (31). They can cause each other. Disease and anomaly are not the least different physiologically (32).

In Fig. 5 is seen a distorted, that is scoliotic, vertebra of a roller squab. The transection shows asymmetry of the vertebra and of the spinal cords. A lower level is shown in Fig. 6. The muscle of the upper part of the illustration to the left of the vertebral column is fibrous and atrophic, the liver to the lower right is more congested than the fellow of the opposite side. The spinal cord is as asymmetrical as is the vertebra. The axis cannot become monstrous without it in some way affecting the parts subsequently produced from it; so axial anomalies are nearly always accompanied by some deviation of structure in the appended parts (33). The tumbling act in the roller is voluntary, he uses it to descend before lighting, the descent being more difficult, than rising by which they avoid hawks, further they often roll in consort. Sometimes it becomes uncontrollable, and they roll from a great height injuring themselves. In the parlor tumbler it is utterly uncontrollable, an outspoken disease. In the air roller, they bring on a fit of tumbling by clapping their wings with great force a few times, then roll over backwards some for a few, some many, times without stopping.

The explanation of the disease is probably to be found in the malformation of the spinal cord. Tapping of the head, shaking it, puncturing the skull, hydrocyanic

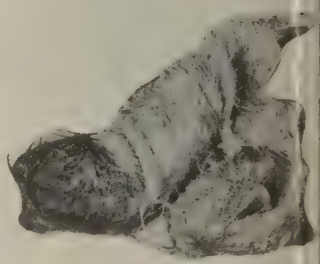

FIG. 8.—Anticlockwise rotation. Inequalities of two halves of the spinal cord due to and accompany rotary twists of the vertebral column.

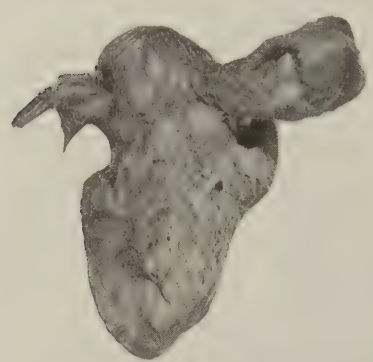

FIG. 6.—Sidebending to right, showing that bilateral asymmetries of two lateral halves of grey and white matter and shape of vertebral column are caused by sidebending.

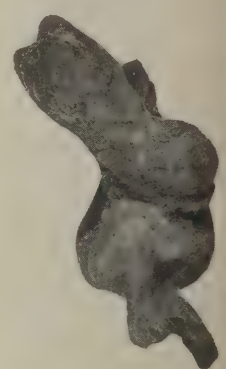

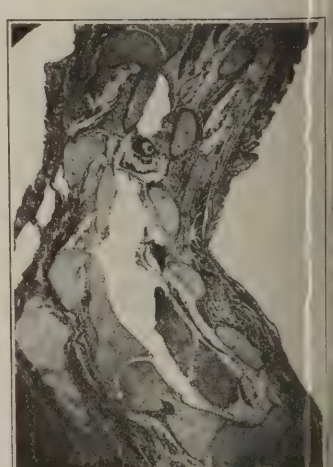

FIG. 9.—Left sidebending, showing that side bending of the body malforms or deforms all parts.

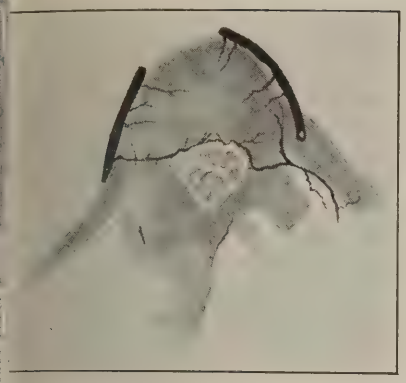
[1]Whether the host or whether the parasite evolves is a question of adaptation or maladaptation of one to the other; for "adaptation is the true cause of every modification" (Haeckel, *History of Creation*, pp. 92, 111, 117, 171; *Evolution of Man*, pp. 158.) "All evil resulting from the nonadaptation of constitution to conditions" (Chapman, *Evolution of Life*, pp. 180), citing Herbert Spencer. Maladaptation is the only disease.



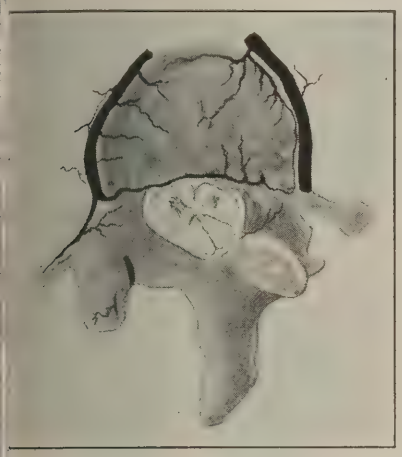


FIG. 11.—Illustration modified by Mr. Erwin Faber from Professor Max Hoffman's *Arteries of the normal and scoliotic vertebral column* to indicate the change in shape and structure of the spinal cord which must ensue from the change in shape of the spinal canal and especially from the decreased amount of nourishment on the one side, and the increased amount of nourishment on the corresponding lateral half which must accompany the evident change in the calibre of the two lateral arteries and their branches depicted.

acid, probably inhibit the inhibitory centres and pathways and the rolling becomes uncontrollable. Brisk flying in the air tumblers and air rollers, stirs the nerves to the spinal cord and excites them and reflexly the muscles of the back are thrown into spasm and the pigeon back somersaults. In the parlor tumbler the least flight stirs up the tumbling impulse.

Fig. 7 shows particularly well the obliquity of a thoracic vertebra: also the oblique malformation of the spinal cord. The anterior grey horn of the spinal cord of the right side is longer than that of the left, while the left posterior horn is the longer. Also, the outline of the cord is malformed and moulded to the shape of the vertebral body and the spinal or vertebral canal. As the right erector spinae group of muscles is atrophic, the muscle bundles have been almost entirely replaced by fatty or fibrous tissue; but the lung on the left side is congested. Therefore disease may be found in either or both lateral halves of a malformed segment. In one instance the sensory mechanism of vasomotor control, or nerve vascular phenomena, being affected, on the other side the motor mechanism being at fault. This corresponds in a way to the diverse mechanisms, inhibition of brain control, or governing sensory mechanisms: and excitation of motor impulse bringing about this spasm of the erector spinæ group.

In chick embryos, between the forty-eighth and fifty-fifth hours, the embryo quits the right position which it has had up to this time; it bends itself and inclines constantly to the left side. It is this inversion of position which affects the inversion of the vessels. For, in the plan above the umbilicus, the veins are anterior and the arteries are posterior; in the plan below (the umbilicus), the arteries are in advance and the veins behind. So far as known, this law holds good for all vertebrates including man.

A Plymouth Rock cockerel chick which had developed "sourcrop," became "cropbound" at three weeks from birth from the shell, and was killed in his fifth week. The transection showed marked deformity of the spinal cord, its outline corresponding to the malformation of the vertebral body, with frank bilateral asymmetry of the grey substance, at the site of a vertebral deformity, a minor curve of the spine.

It is true that asymmetry is seen in most of the viscera of vertebrates generally, and even in some of the head bones, especially about the nose of the toothed cetaceans (whalelike mammals), but the asymmetry is entirely concealed or not conspicuous externally (34).

EMBRYOLOGY OF MALFORMATIONS OF BODY SEGMENTS INCLUDING VERTEBRÆ, SPINAL CORD, NERVES, VESSELS, MUSCLES, VISCERA, LYMPHATICS, AND SYMPATHETICS

Under the heading of comparative anatomy and comparative embryology were described the malformations of the snail by Conklin; of the lancelet by Kellicott; the flat fishes Kingsley; the chick by Serres; the squab; the whalelike mammals (Cetacea) by Kingsley. Swedenborg's views on the importance of spirals were mentioned. In man, the embryo entire designs a double spiral, cephalic and caudal, with the dorsal arc as a union—the close approximation of this double spire has increased the deviation of the head and tail to left and right. When the general movement is parabolic the dorsal curve, exhibited only at this moment, is elliptical. When the movement of the embryo is spiral, the cephalic curve, then the dorsal curve, becomes spiral also. To give these curves absolute numerical values, would be to destroy all truth by suppressing all possibility of individual variation among embryos (35). The embryo tectonic curves become thus a criterion of the normal or abnormal character of this or that particular embryo (36). Falk describes many instances of embryonic malformations accompanied by axial deviations (37). Ballantyne, writing independently, does likewise. Moreover, he says of morbid agents not peculiar to the embryo, in the embryo we call them teratogenic, in the fetus and adult they are called pathogenic, but there is no sufficient reason for believing that they differ one whit. For Féré's researches showed that experimental teratogeny fell in line with experimental pathology (by the use of toxins of bacteria and poisons). Probably the causes of disease are just the causes of these malformations (38). As embryo tectonic curves become a

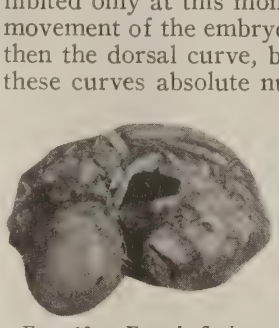

FIG. 10a.—Forced flexion. Extreme flexion of squab's neck.

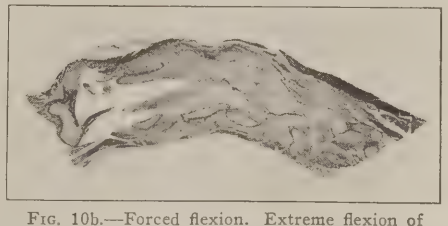

FIG. 10b.—Forced flexion. Extreme flexion of a squab's neck. The resulting deformity of the spinal cord is due to limitation of movement of the surrounding vertebral column fixed in a flexed position.

criterion of the normal or abnormal character of the embryo; so curves, i. e., malformations of body segments become a criterion of the normal or abnormal character of the adult. For the phenomenon of curves (scoliosis) should be considered universal (39). The phenomenon of variation is universal (40). As the axis cannot become monstrous without in some way affecting the organs which are subsequently produced from it; so axial anomalies are nearly always accompanied by some deviation of structure in the appended parts (41).

CURVATURES AND MALFORMATIONS OF THE SPINAL CORD ACCOMPANYING CURVATURES AND MALFORMATIONS OF THE SPINE

In a scoliotic vertebra what is gained on the right side is lost in size on the side opposite (42). The arteries on the concave side are directed backward, they are wider on the concave side;—that such occurrences cannot be without influence on the nourishment of all parts, is selfevident (43). Figs. 2 and 3, modified from Hofman (44), illustrate the vascular changes accompanying a scoliotic vertebra. The difficulty of flow of the venous blood is gravely disturbed (45). On this anatomical behavior, results an asymmetry of the vertebral body, caused by the increased growth favoring the convex side of the vertebral half. On this present growth is explained, moreover, the asymmetry of the vertebral arches and their adnexa (46). The spinal cord (in scoliosis), does not lie in the middle but with its dura is bent to the right arch, which corresponds to the concave side (47).

FIG. 12.—Photographs of his embryo models reproduced through the courtesy of Professor MacCallum of the Wistar Institute and of the department of anatomy in the University of Pennsylvania Medical School.

The illustrations (modified from Bachman) show a bilateral asymmetry of the grey and white substance of the spinal cord in scoliotics. In describing an anomaly of the spinal cord in an embryo, Fischel says, of the spinal cord and canalis centralis: "Because of the winding curvature of this region of the body, the last mentioned space" (central canal and spinal cord) "appears to be cut tangentially." "The embryo possessed a slight bending" (curve), "because the illustrations show asymmetry" (48). Therefore as scoliosis is universal and as variations are universal and bilateral asymmetry is universal (49); and as we are able to trace the mutability of individuals to the mechanical conditions of nutrition; and because the spiral type owes its peculiarities entirely to mechanical conditions; and as this form derives the power of infinite variation (50) and as axial anomalies are nearly always accompanied by some deviation of structure in the dependent parts (51): It might be assumed that many, if not most, variations were accompanied by some deviation of the spine. "Without one being dependent on the other, but both depending on a similar cause" (52). In other words perhaps nearly all these phenomena are dependent on embryo tectonic, or even postnatal mesial or lateral curves of body segments.

Therefore change in shape of body segments includes change in shape of all structures composing the altered or malformed segments, including spinal cord, nerves, bloodvessels, vertebral column, ribs, and all structures and organs found in transverse sections of embryos and adults alike. Not only are these factors correlated and interdependent, but all are affected by exaggerated body-movements, or by limitations of these movements, arresting the body when bent forward, backward or to either side. And the illustrations show these malformations and are subject to experiment (53). Further many diseases in adults accompany severe scoliosis, according to Hofman, Bachman, Caprioli and Codivilla; and malformations in embryos accompany curves according to Falk, Ballantyne and also Boujard. By inscribing a smaller circle within a larger one it may be seen that the smaller circle or curve is relatively more crooked than the larger. Therefore small curves show relatively at least as much deformity among fewer segments; in the large curves a greater number of segments but less relative deformity of each segment. The ribs splinting the deformity make the deformity of minor curves less obvious.

Heidin describes a case of heterotopia of the spinal cord and says: an idea is given us of the frequency and diverse forms of heterotopia. He cites other cases with histories from Krönthal; Fürstner and Zachner; Bucholtz's case showed bilateral asymmetry; Bucholtz again; Kohler and Lick; Pick reported three or four cases; Köppen one of heterotopia spinalis; Heidin further says: "It is well to consider therewith that many of the bearers of such spinal cords die a sacrifice to disease of other organs, e. g., bronchitis or pneumonia (54). Marburg describes a case of amyotrophic lateral sclerosis secondary to heterotopia; he says, "perhaps we see here the congenital disposition in Strumpell's and Marie's sense; and that R. Stern has found a form of transection of the cord occurs which demands the earliest childhood (55).

(To be concluded.)

Practical Therapeutics

TREATMENT OF CERTAIN CONDITIONS COMMON TO MOST CHRONIC DISEASES

J. Madison Taylor, A.M., M.D.

Philadelphia, Pa.

Formerly Professor of Physical Therapeutics and Dietetics, Medical Department, Temple University

The topic submitted is one chief feature of deteriorative diseases of middle life, i. e., regulation of the acid alkali balance of the blood.

It has long seemed to me, and so presented in teaching, that so soon as clinicians habitually take under consideration certain common denominators, expotentials, integers of chronicities—from whatsoever causation—we shall make better headway and achieve greater uniformity in results. Thus the clinical background becomes simplified; we get a clearer idea of the materials with which we are working and learn how to cover more ground in our efforts.

Recent personal experiences directed my attention to what appear good possibilities for limiting the progress of deteriorative diseases of middle life and for overcoming many of their heretofore obdurate effects. The means suggested begin with dietetic modifications designed to lessen tendencies toward acid alkali imbalances in the blood.

To this disturbance has been traced much of cellular and structural deterioration, which again leads toward the terminal phenomena or the real causes for much decrepitude and untimely death.

While these recommendations are in part therapeutically practicable they are also submitted in the hope that, through wider cooperation, more safe and sure conclusions as to procedure shall be reached.

Postulates: When for any reason the automatic selfregulative and defensive mechanisms begin to be overborne, get out of gear, refuse to work, it becomes desirable to set them right *cito, tuto et iucunde,* also from as far up the line of causation as is possible and in the most radical particulars.

We must begin where nature has left off, where the despotic impacts, pressures or repressions of artificial complexities of life start to confuse function. Thus the factors of safety are unduly invalidated.

One promising direction for effort is through readapting certain habits of life, in particular of diet, hence of metabolism. We must here proceed with caution being careful not to urge correction or revolution of man's most cherished habits, customs, prejudices; otherwise we plunge into the impasse, or barrier, raised by social sanctions and folkways; also the verging currents of fashion in artificialities of taste, discriminations, especially cravings for what comes to be desired but is in no sense needful.

The wisest course, it would seem, is to deal with some of the fully formed and accepted appetites and commendable foods, "play them up," and apply such modifications to these and their congeners as shall constitute a valuable new departure.

My proposition or query is: Why not make larger, more massive, systematic use of citrous fruits? In oranges, pamelos (socalled grape fruit), tangerines, tangelos (a delightful cross of tangerines and pamelos), also lemons, limes, etc., there resides the largest amount of alkaline basis (ash, etc.) whereby the blood is furnished with, and is sustained in, its proportionate alkalinity.

These are now of widely recognized value in small amounts; are regarded as excellently healthy *luxuries.* There is ample ground for regarding them as *necessities,* not only in health, but especially where the blood tends to lose its alkali reserve. Socalled acidosis lies at the base of a large variety of acute, as well as deteriorative diseases. This, in the middle-aged and sedentary, is a constant menace. It can also be prevented by supplying *adequate amounts* of suitable corrective elements.

Already orange juice has become standardized for certain infantile and childish diseases, as preventives of acidosis; so fatal in the young. Also in marasmatic, scorbutic and rachitic conditions. Now lemon juice is recommended, added to milk for infants and coming to the front.[1]

Certain erroneous notions still persist, among the profession as well as the public, to the effect that acid fruits act harmfully in conditions where the blood is supposed to be acid, especially for those who enjoy the distinction of being told they are "gouty," "rheumatic," or of "a peculiarly sensitive constitution." These are echoes of long abandoned professional opinions which arose before the real facts were so generally known. I have in common with many others, urged such phobiacs to eat freely of ripe fruits and always to their radical advantage. Incidentally where there occurs some local or temporary digestive disturbance it can readily be corrected. To the juice of lemons or oranges a little added potassium bicarbonate will do. The literature is full of isolated facts along this line which it is my purpose to coordinate and integrate when greater space is at my disposal.

At the annual meeting of the American Clinical and Climatological Association in May, 1924, I presented these ideas to a score or more of physicians in charge of special sanatoria, which seemed to interest them greatly. As to whether acidosis is a constant feature of chronic tuberculosis they had not as yet adequate data but offered to learn. While in Florida during the past winter, convalescing from a gallbladder operation, I was distressed at the pitiful waste of fruit occurring in overbearing years. Untold millions rot upon the ground. The owners could not afford to gather and ship them.

A number of prominent fruit growers assured me they would gladly ship these fruits by the carload, free of cost—except for expense of picking and transportation—to sanatoria, provided those in charge would undertake to make clinical investigations. They also said that should there be adequate demand they could double or quadruple the output.

PROPOSITION

I would urge that physicians in charge of hospitals, sanatoria, homes, and similar institutions,

[1]See "The Value of Milk Acidified with Lemon Juice," by A. F. Hess and Milton J. Matzner, *J. A. M. A.*, May 17, 1924.

wherever chronic or socalled incurable or decrepit cases are grouped, the basis for whose decrepitude is faulty metabolism, should attack this problem from the angle of acid alkali balance of the blood. Such cases are at an impasse or dead point due in large part to some metabolic obstruction. When this shall have been removed they should be better able to respond to whatsoever other remediation is indicated, and thus be qualified to "carry on."

Is it not fair to assume that this impetus, release, catalytic substance may reside in supplying massive amounts of fruit juices?

The only answer worth while is putting the question to the test of experience on a comprehensive scale. Why not institute special *citrous fruit cures,* as is done in Europe with grape cures, cherry cures and the like.

Could means, any better, or as good, be devised for revolutionizing the intestinal flora? Why not send suitable "cases" to the countries where these fruits are superabundant and try out "cures," say to Florida, Louisiana, along the Gulf of Mexico, or California.

PROFUSE HEMATURIA SUCCESSFULLY TREATED BY ORAL ADMINISTRATION OF A COAGULANT PRESCRIBED FOR PATIENT'S USE

M. K. WILLOUGHBY, M.D.
Morris Plains, N. J.

Although all cases of hematuria are not necessarily serious, the condition may be the forerunner of consequences so grave as to justify its recognition with deep concern. The problem of the proper mode of procedure, once the finding has been established, has long been one which has provoked much discussion, and the resultant theories deduced are numerous and varied.

While it is of course realized that the condition is but a symptom which may be due to one of many causes, the essential factor, undoubtedly, is the arrest of the bleeding at the earliest possible moment.

Chronic nephritis, being the most frequent source of urinary bleeding—possibly the most common, according to Young (1), Woodward (2) and others—I believe my experience in the case of a child suffering from this condition to be worthy of record, in establishing a new source of treatment and in throwing much light on the complete arrest of a profuse hematuria.

Although transfusion has been considered one of the most valuable adjuncts in combating conditions of bleeding, its efficacy was but temporary in the case under consideration. A history of the case follows:

CASE.—Boy, aged ten. Family and past history not important, except the patient had influenza in 1918.

March, 1921, the patient was taken ill with hematuria, which persisted for three months. The patient became so anemic that a transfusion was done. Hematuria returned three months later, but was of short duration.

On April 16, 1923, the patient was first seen by me, and he was then suffering from profuse hematuria. Laboratory tests showed a moderately advanced nephritis. Treatment on the first day consisted of one c. c. of fibrogen, oral administration, in ice water, on an empty stomach, three times a day; on the second day, two c. c. of fibrogen, likewise, in ice water, twice a day; on the third day, one c. c. of fibrogen administered subcutaneously, before breakfast.

On the second day, only slight traces of blood were perceptible, while on the third day no trace of blood was present, and the result has been a complete absence of hematuria. On July 5th the patient went in swimming in cold water, and another attack of hematuria followed. He was given two c. c. of fibrogen in ice water every three hours, for two days, and on the third, there was no visible signs of hematuria.

The writer had previously employed fibrogen with marked success, in nosebleed, and in minor surgical work. This instance, however, marks the first test of its efficacy for internal hemorrhage, and as indicated above, results have proved most remarkable.

The fact has now been generally recognized that fibrinogen is one of the strongest coagulants which normally controls the mechanism of hemorrhage in the body. It is present in blood plasma as a soluble protein—blood fibrinogen—which, in the process of coagulation, is transformed into an insoluble form, namely fibrin. There are times, however, when this mechanism of the body, normally so well adapted to the clotting process which controls the loss of blood, fibrinogen is one of the strongest coagulants which control the mechanism of hemorrhage in the body. It is present in blood plasma as a soluble protein—blood fibrinogen—which, in the process of coagulation, is transformed into an insoluble form, namely fibrin. There are times, however, when this mechanism of the body, normally so well adapted to the clotting process which controls the loss of blood, becomes impaired. In such instances, therefore, it seems but logical to supplement the deficient quantity of fibrinogen and thus assist nature in the process of coagulation. Fibrogen is a tissue fibrinogen, a natural coagulant of the tissues isolated in accordance with the theories and technic of Mills.

Numerous tissue extracts have been recommended and put to the test in hemorrhagic conditions, but none so far, in my estimation, have yielded the same results as has this particular product. This is no doubt due to the fact, as pointed out by Mills (4) that this powerful coagulant—fibrogen—is prepared from calves' lung which was found more active than extracts of any other tissue. To quote from this writer: "Tissue extracts were tested as to their thromboplastic activity on the blood both intravascularly and extravascularly. Lung extracts were found far more active than the extracts of any other tissue, kidney coming second, and then heart, brain, spleen, thymus, testes, skin, somewhat in the order named. The remaining tissues were weakly active as compared to lung, some of them showing very slight thromboplastic action."

In a later publication (5) this writer adds: "The addition of further tissue fibrinogen to the escaping blood is advisable, but it should not be added in the

form of crude tissue extracts, because these contain, in addition, albumins which are toxic to the body. It has been shown that tissue fibrinogen has no toxic effect on the body unless clotting of the blood is induced. The albumins, however, possess a histamine like action in every case, and are quite toxic. The use of the purified substance is therefore indicated, especially since its ease of preparation renders it almost as accessible as the crude extracts."

This new product can be administered, with an equal measure of success, either locally, subcutaneously, or orally. When given subcutaneously, there is no danger of clotting of blood in the bloodvessels. The clotting time of the blood is reduced about one hour, when administered in this way. Results, however, are most gratifying when given by mouth when the stomach is empty and has its normal motility. Results are obtained within half an hour or less when given in this way. In fact, it is the only coagulant known to me which can be prescribed for oral administration in a case of hematuria, and which can be taken by the patient as required or prescribed.

The hematuria having thus been controlled and the danger of anemia and, possibly, of more disastrous consequences being eliminated, it then becomes a comparatively simple matter to proceed with general diagnostic measures. It follows then, that the patient's vitality being restored with the arrest of the bleeding, such remedial measures as are considered imperative may then be instituted with every promise of the patient's cooperation.

Intravenous Injections of Sodium Citrate in Obliterating Thromboarteritis with Gangrene.—J. Troisier and A. Ravina (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, May 15, 1924) report an almost typical case of Buerger's disease in a man aged forty-five years in which the need of amputation seemed imminent on account of gangrene of the anterior third of the sole, the first three toes and the tissues on the inner aspect of the os calcis. Stress is laid on the high cholesterol content of the blood serum in this case, viz., 2.4 grams, in spite of the absence of renal or hepatic symptoms, suggesting that there may have been a disturbance of the metabolism of the lipoids with heightened functioning of the adrenals. Three features of Buerger's disease are seldom wanting: Increased blood viscosity, increased number of red cells, and increased blood coagulability. In Vaquez's disease the authors had already noted temporary reduction of the red cells by ingestion of large doses of sodium citrate, which also reduces the coagulability and viscosity of the blood *in vitro*. In the present case the authors adopted W. A. Steel's plan of administering sodium citrate, but used larger and more frequent doses. Twenty-eight injections, nearly all of four grams of the salt, and the first twenty-four given on successive days, were administered. Hot air and ether dressings were also used for the gangrene. The severe pain rapidly subsided, the gangrenous process retroceded until only the tips of the toes remained ulcerated, and the patient was enabled to resume his ordinary mode of life. The authors recommend the daily injection, at the beginning of the arteritis, twenty mils of a sterilized thirty per cent. solution of sodium citrate, containing six grams of the salt. When improvement begins, the dose is to be reduced to four grams, to obviate the slight facial redness and breathlessness which the drug sometimes produces, especially in patients with hemiplegia or other paralyses. Later, the injections may be given only every two or three days, and the drug may be given subcutaneously or even by the mouth. The treatment should be continued until collateral circulation has been established. The citrate injections do not cause pain, even if the fluid passes outside of the vein, and are never followed by necrosis. The vein retains its softness if solutions not exceeding thirty per cent. in concentration are used.

Massive Doses of Digitalis in Auricular Fibrillation Without Heart Failure.—Julius Jensen (*Lancet*, April 12, 1924) reports his results as follows: The heart rate was in most cases affected to some extent on the evening of the day of administration, about twelve hours after the first dose had been given, and the average fall in rate by this time was ten beats a minute. This fall was maintained the next morning, and later on in that day a further fall of ten beats a minute occurred, though no more digitalis had been given. The quality of the pulse was much improved, the volume being larger. In a few cases coupled beats appeared temporarily. This control of rate, however, was not very stable, as counts taken after meals or after slight exertion or excitement nearly always showed that the pulse had risen toward its original rate. Very often, also, there was a relapse lasting for a few hours without any apparent cause. The total duration of the effect was four to fourteen days. No definite diuretic effect was observed in any case. The patients all felt better and said that they had less palpitation. As all signs of failure were absent in the cases observed, there was no opportunity of judging the effects of digitalis on the general condition. Apart from occasional coupling of the pulse in two cases there were never any indications of overdosage. Nausea and vomiting were never seen, showing that the vomiting which sometimes occurs early in administration of digitalis in heart failure depends far more upon the failure of the heart than upon any irritant effect of this drug on the stomach.

Treatment of Anthrax with Intravenous Injections of Neosalvarsan.—O. Grasser (*Wiener klinische Wochenschrift*, March 13, 1924) obtained some excellent results with intravenous injections of neosalvarsan. Light cases were given only a single injection of 0.45 to 0.6 gram neosalvarsan and more severe cases were given two to three injections at intervals of two days. These resulted in an astonishingly rapid diminution of the swelling and a marked improvement in the general condition of the patient.

Historical Medicine

The History of Diabetes*

CHARLES GREENE CUMSTON, M.D.,
Geneva, Switzerland,
Lecturer on The History of Medicine and Medical Philosophy in the University of Geneva

The presence of sugar in the urine of certain patients unquestionably was known in the most remote antiquity, but Celsus was the first to describe it from the clinical viewpoint. Galen regarded the process as due to weakness of the kidneys and for centuries this error was accepted until the year 1568, when Trincavella pointed out that the urine was composed of unaltered fluids ingested by the subject, since it possessed the taste of medicinal drinks taken by the patient. Hence diabetes resulted from the intake of sweet drinks containing sugar in excess.

Paracelsus, Sylvius and van Helmont each put forward certain theories regarding the etiology and pathology of this morbid process, but they are so hazy that they need not be considered. In 1754, Richard Mead affirmed that diabetes was an affection quite independent of the kidney, and then Sauvages published his *Nosologia methodica* in 1763, in which he described seven kinds of diabetes which naturally singularly complicated the subject.

In 1775, Dolseux pointed out that diabetic urine had a sourish odor and also showed that the blood serum of diabetics possessed a taste of sugar, thus proving that the sugar in the urine was not formed in the kidney. It is obvious that Dolseux's discovery was an enormous step in the advancement of our knowledge of the pathology of diabetes, and in point of fact it was generally accepted by the profession of the day.

In 1815, Rollo, an English surgeon, supposed that diabetes was a disease of the stomach resulting from corrupted gastric juice. Then, in 1815, Chevruel showed that the sugar contained in diabetic urine was identical with grape sugar, and this had the fortunate result of reducing the number of kinds of diabetes from seven to two, namely, diabetes mellitus and insipidus.

Little more progress was made until 1821, when Tiedemann and Gmelin discovered that sugar formed normally in the digestive tract of animals quite independently from carbohydrates. Bouchardat then suspected that this transformation took place more rapidly in the case of diabetic subjects and showed that the amount of sugar contained in the urine was in direct ratio to the amount of sugar and carbohyfunction of the liver did not exist, but this theory is no longer found to be exact, it nevertheless was fruitful in results.

It was just at this time that Claude Bernard demonstrated that—contrary to what was then the established opinion—certain animal viscera can manufacture sugar just like plants. This glucose forming function belongs particularly to the liver under the control of the bulb, which when pricked with a needle will immediately result in glycosuria. This well established experiment was unsuccessfully attacked by L. Figuier. Next, by his famous experiment of the washed liver, Bernard showed that the hepatic gland manufactures glucose postmortem (quite independently of the blood) from a carbohydrate contained in the hepatic parenchyma and which he later on called glycogen. Contrary to Bernard's teachings that glycogen did not exist as such in the liver, Rouget was able to extract it from various other animal tissues.

In 1859, the distinguished English physician, Pavy, who had been a pupil of Claude Bernard, thought that from his animal experiments the glycogenic functions of the liver did not exist, but this theory found little support from other investigators.

As has already been said, Claude Bernard discovered that a prick inflicted to the bulb produced glycosuria and that division of the splanchnic nerves prevented this injury to the bulb from giving rise to glucose in the urine. Shortly after this, the great physiologist produced glycosuria after the exhibition of curare and formulated the following principle, namely, that an animal becomes diabetic if its functions of relation are suppressed, the functions of nutrition remaining intact.

To sum up, it may be said that Claude Bernard's experiments prove that the animal organism when submitted to a meat diet manufactures sugar and that sugar is principally produced in the liver. Hence he concluded that the liver was the seat of diabetes. However, the Leipzig school doubted the reality of hepatic glycosuria, and others as well. Pfluger did not admit that the functioning of a given organ could be deducted from the analysis of the venous and arterial blood. Seegen found more sugar in the blood of the suprahepatic vein than in the portal vein, but this fact he attributed to transformation of albuminoid matter, because he supposed that the amount of glycogen and sugar contained in the liver did not vary, a fact that has not been confirmed. Continuing his experiments he at length was led to discover a glycosuria which developed only after the ingestion of carbohydrates, due to insufficiency of the hepatic cell, and yet another form of glycosuria arising without the ingestion of carbohydrates and depending upon the fact that numerous elements of the animal organism had lost their faculty of destroying sugar. But in none of these cases was the elimination of sugar exaggerated.

Starting from the inexact fact that the sugar in the blood of a diabetic is without action on polarized light, Cantani put forward the idea that it was an isomer of glucose, less easily destroyed by the organism than glucose and whose production was the result of a change in the pancreatic cells.

Bouchard attributed diabetes to faulty sugar metabolism while others regarded it as a hyperpro-

*Summary of a lecture delivered during the course on medical history at the Faculty of Medicine of the University of Geneva.

luction of sugar, some organic perturbations existing esulting in the formation of sugar instead of fat.

The well known work by Frerichs, published in 884, is purely clinical, although he erroneously tates that absorption of sugar or fat has no in- uence upon the content of the urine. In 1889, Hoffmeister studied the assimilation of various ugars in dogs and found that for each subject and ach kind of sugar there was a limit of assimilation eyond which the surplus of sugar absorbed, was liminated in the urine.

At this point, we will retrace our steps to the ear 1788, when Thomas Cawley published the first ase of diabetes mellitus accompanied by lesions of he pancreas (*London Medical Journal,* vol. 9, 788). The process was developed in about six nonths and autopsy revealed a pancreas stuffed with alculi, while the right end of the gland was hard nd waxy. In 1833, Richard Bright published a aper in the *Medico-Chirurgical Transactions* in hich he calls attention to the presence of fat in the eces—a symptom to which little importance had een attributed up to that time—and among the sev- ral cases recorded was one of diabetes. In 1846, Bouchardat pointed out that morbid changes in the ancreas play a part in the production of glycosuria nd again repeated Haller's experiments of extirpa- ion of the pancreas although his results were incon- lusive.

In 1852, Traube studied the digestion of fats in iabetes and with the methods at his disposal at the ime, made dosages of the fecal fats. The results were uncertain because the patient under observation ngested so large a quantity of fats that they would aturally give rise to residual fat in the feces.

In 1854, Jeffrey Marston, of Newcastle, published he report of a case of diabetes gravis with fatty tools, in the *Glasgow Medical Journal,* and from his time on more cases were reported. Claude Ber- ard noted a small atrophic pancreas in a diabetic hile Frerichs, in 1862, reported nine instances of iabetes with pancreatic lesions, there being atrophy nd fatty degeneration of the gland in five.

In 1864, von Recklinghausen found a pancreas at utopsy of a twenty-six year old diabetic, similar to hat recorded seventy-six years previously by Caw- y, and Jaccoud mentioned pancreatic atrophy as mong the lesions of diabetes, while a number of ther observers, too long to mention, reported in- tances of gross lesions of the pancreas in autopsies f diabetic subjects. However, we must come to the ear 1878, when Lancereaux finally enunciated the elationship existing between lesions of the pancreas nd the production of glycosuria and built up his heory of pancreatic diabetes. Then enthusiasm pread and many observers maintained that most ases of diabetes mellitus were due to pancreatic sions. This enthusiasm was combatted by Lan- ereaux, who maintained that there was only a type f diabetes dependent upon pancreatic changes and t the Congress of Medicine held at Lyons in 1894, his distinguished pathologist and clinician admitted n a general way the identity of pancreatic diabetes nd diabetes with emaciation. Further observations n this respect were recorded by Silver and Irving, Rhüle, Israël, Guelliot, Notta, Laplick, Ferraro and thers but experimental proof of Lancereaux's theory was wanting. Therefore, great was the joy, when in 1889 von Mering and Minkowski were suc- cessful in producing glycosuria, marked emaciation and death in animals following complete removal of the pancreas, and fortified the opinion of the part played by this gland in the production of diabetes. Study of the subject continued and investigators modified their technics. Instead of complete extir- pation of the gland at once, the organ was removed successively in three portions. Hédon, Gley and Thiroloix produced progressive atrophy of the pan- creas by various substances injected through Wir- sung's duct and the atrophy gave rise in dogs to glycosuria. In 1895 Sandmeyer produced a special form of diabetes by removing seven eighths of the gland; the disease progressed slowly, the glycosuria did not subside when the animal fasted and was in- creased by ingestion of carbohydrates. This form was also reproduced by Hédon.

Up to this time Claude Bernard, Schiff, Bérard and Colin, Klebs and Munk, Senn, Martinotti, de Dominicis had only obtained very variable results experimentally. The results obtained by partial or total extirpation of the pancreas by Gley, Hédon, Lépine and Thiroloix, with or without subcutaneous graft of a bit of the gland, differed totally. In com- plete removal an intense diabetes ensued; partial extirpation was followed by a mild diabetes which gradually became severe, while in some instances no glycosuria occurred at all. Lastly, in depancreatized dogs, but who had been grafted with the gland, dia- betes only arose when the graft was removed.

Certain investigators supposed that the causal fac- tor of diabetes was a lesion of the pancreatic acini. In 1891, Lemoine and Lannois described an intra and interacinous sclerosis which they believed to be the most important lesions in the genesis of diabetes, while Hausemann, Lépine, Karakascheff and Herx- heimer considered the lesion of the parenchyma as exclusively diabetogenous, because they found the islands of Langerhans normal in autopsies on diabetics. Following the initial experiments of La- guesse in 1893, who attributed to these islands an important part to the internal secretion and its glyco- regulating action, Szobolew, Herzog, Dieckoff, Thoinot and Delamare and others regarded insular secretion as the anatomical cause of diabetes. Opie described the lesions of the islands, viz., interlobular and intralobular and periacinous cirrhoses and hyalin degeneration, while Weichselbaum, in 1910, mentions hytropic degeneration and a decrease in the number of islands, ending in atrophy of the pancreas. In 1915, Arrigo Visentini ligated and resected the excre- tory pancreatic ducts in dogs, this giving rise to total atrophy and sclerosis of the gland, alone the epithe- lial elements remaining, to which Visentini at- tributed the signification of the islands. The animals did not develop glycosuria, but this did arise when extirpation of the remaining atrophied pancreas was done. From this Visentini concluded that the origin of the glycoregulating disturbances was in the islands and maintained that histologically the islands of Langerhans are quite independent of the tissues surrounding them.

As far back as 1905, Gellé showed that the islands are rare and offer important lesions in diabetes and pointed out that there were insular acinous transi-

tional types of the disease which are retrogressional forms. Thus diabetes is characterized by a tendency of the islands to transform into acini, hence rarefaction of the islands with their functional decrease. Curtis, of Lille, also maintained that a lesion of the acinous tissue exists which hinders the acinous insular transformation, hence the rarity of transitional forms developing from the acinous to the island.

Many observers are, however, less affirmative than Gellé who in 1913 stated that he had never met with an autopsy of a diabetic in which very advanced lesions of the pancreas did not exist. Hausemann, Szobolew, Schmidt, Kasahara and many others have reported instances of normal pancreas in autopsies on diabetics, while Russel and Cecil have shown that the number of islands may alone be decreased without any other evident lesion being present.

For some time past pancreatic diabetes has been looked upon—especially by the German school—as a peculiar form of this affection characterized by functional disturbances of the exocrine and endocrine secretions of the pancreas and Naunyn and Umber, especially, have described the symptomatology and the signs of insufficiency of the external secretion, while the American school, headed by Joslin, Banting and Macleod, have largely contributed to this subject.

Aristotle as a Biologist

Dr. Charles Singer, of London, writing recently on Aristotle, points out that the history of the scientific writings of Aristotle is a series of reversals of verdicts. His genius for system caused his works to replace all that went before and the Aristotelean view of the universe ruled in later antiquity. As antiquity passed into the Dark Ages the West lost all his works save those on logic. In the thirteenth century his scientific writings were rediscovered. They were forbidden, but after a contest were accepted once more. "Scholasticism" was built on them and Aristotle ruled more absolutely in Christian Europe than ever in pagan Greece and Rome.

With the advent of the scientific renaissance, an event later than the artistic or literary renaissance, the reputation of Aristotle again fell. His conception of a limited universe with the earth in the centre and the planets moving around it was attacked by Copernicus and later by Galileo. The battle raged back and forth; its outcome was the utter rout of the Aristotelean. One after another the doctrines of Aristotelean physics were undermined. A notable incident was the demonstration by Galileo that the rate of movement of falling bodies is a function not of their weight but of the period of their fall. The matter was put to a dramatic test by dropping two unequal weights from the top of the leaning tower of Pisa. The philosophy of Aristotle, or rather a medieval interpretation of it, continued to be taught, but among men of science he was now discredited. The midnineteenth century brought the last reversal of verdict. Beginning with Johannes Müller, scientific men turned from the physical to the biological works of Aristotle. A series of striking verifications of his biological investigations succeeded one another. With the advent of evolutionary ideas interest was further awakened. From the problems of generation and development biologists found his scientific works a mine of suggestion. The very problems that most concerned them were here set forth with an acumen and mastery of statement never excelled. His reputation as a biologist has since progressively risen and it may be safely stated that Aristotle now takes his place among the very greatest investigators of all time. What, asks Dr. Singer, is the cause of this series of changes? The answer is not far to seek. Aristotle, who possessed the most supremely equipped intellect of any mortal, attempted more than mortal could accomplish. He sought to set forth a complete scheme of the universe. In doing this he relied upon others for his physics and astronomy. In biology, however, he observed with his own eyes. Though no physicist he was a naturalist to his finger tips. What then were his actual achievements as naturalist? Observations and inferences. We find him investigating some five hundred species of animals, and recording innumerable observations. We may mention his wonderful acuteness in perceiving that, in a single species of Mediterranean dogfish, the process of development resembles that of the higher warmblooded animals in that the young is linked to the mother's body by a placenta. The verification of this amazing statement immediately drew the attention of men of science. No less remarkable is his account of the life of bees, of the generative process of the octopus, of the feeding habits of the torpedo fish, of the way the socalled frogfish secures its prey, of the four chambered stomach of ruminants, and of the habits of the male of a species of catfish in guarding its young. The series might be multified indefinitely. As for theory he laid the basis for classification by his idea of a "Ladder of Nature." The conception of species comes from him: the very word is a Latin translation of one that he uses. From his writings may be drawn up a classification adopted by naturalists.

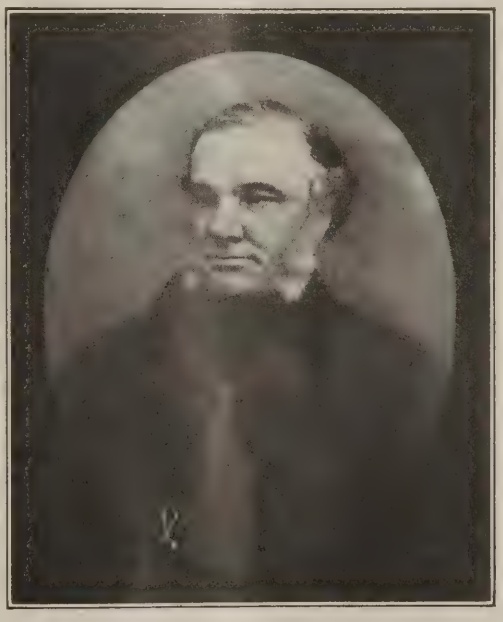
Most masterly is his treatment of questions of heredity and generation. The philosophical naturalist must therefore always return to Aristotle for refreshment and inspiration. One feels that had he been able to devote more time to purely biological work he would have formulated a doctrine of organic evolution; he was evidently moving in that direction. Even as it is, he sets forth a doctrine of heredity almost identical with that formulated by his legitimate successor, Charles Darwin. In 1882 that great naturalist wrote of his mighty predecessor: "From quotations I had a high opinion of Aristotle's merits, but I had not the most remote notion of what a wonderful man he was. Linnaeus and Cuvier have been my two gods, though in very different ways but they were mere schoolboys to old Aristotle."

Contributors to the Science of Medicine

Thomas Addison

The name of Thomas Addison is one of the great names in medicine and, perhaps, on the whole, the greatest of those which have gained fame for themselves and Guy's Hospital. Astley Cooper shone as a surgeon, William Gull as a physician but Richard Bright and Thomas Addison were original thinkers and workers and made notable additions to the sum of medical knowledge. It is true that Bright effected one of the greatest revolutions, if not the greatest revolution, since the time of Harvey in our habits of thought and methods of investigating morbid phenomena and tracing the etiology of disease. But Addison in his particular line of research was quite as original and moreover, he was gifted with a remarkable faculty for imparting knowledge. He was a great teacher, as well as a great thinker and worker.

The three shining lights of Guy's Hospital shone at the same time, for although Cooper was born some twenty years earlier than Bright or Addison and died some twenty years before these two their careers at Guy's overlapped for a time. Thomas Addison was born in 1793 near Newcastle in the north of England where he received the chief part of his education. He was well grounded in what were known as the humanities and gained a masterly knowledge of Latin. He then went to Edinburgh to pursue his medical studies. In 1815 he took his degree in medicine and came to London to practise. He was first appointed house surgeon to the Lock Hospital and then studied skin diseases, and was probably the first physician in London to give occasional clinical lectures on diseases of the skin. It was not until 1820 that he went to study at Guy's Hospital and was appointed physician there in 1824. In 1827 Addison was appointed lecturer on materia medica. In 1829 he and John Morgan, surgeon to Guy's, published an essay on The Operation of Poisonous Agents on the Living Body. This was the first serious investigation in England into the phenomena of general poisoning.



THOMAS ADDISON

In 1837 Addison was appointed full physician. At the same time he was appointed joint lecturer with Dr. Bright on medicine. They agreed to write a book on the *Elements of the Practice of Medicine* of which the first volume only appeared and this was written by Addison. He wrote valuable monographs especially on diseases of the lungs in which he took particular interest. In his essays on the Anatomy of the Lung and Pneumonia, he demonstrated the mode of termination of the bronchial tubes in the air cells, and how these were packed closely together; it being a mistake therefore to regard pneumonia as an inflammation of an imaginary parenchyma lying amongst them. He showed that the real seat of the inflammatory process was the air cells themselves. As regards the chronic destructive diseases of the lungs in phthisis, Addison was the great instigator and supporter of the view that the disorganizing changes were due to inflammatory processes, whether tubercle was present or not, and that these changes were not due to the softening of tubercle, according to Laennec and his school. Addison also contributed valuable papers on the diagnosis of chest diseases. However, the achievement of Addison which dwarfs all his other achievements and which will ever immortalize his name was the discovery of a disease of the suprarenal capsules which slowly proves fatal by exhaustion accompanied by a general discoloration of the skin.

This discovery has been often spoken of either as a kind of guess or due to some peculiar inspiration with which Addison was endowed; but so far from either of these suggestions being true, his memoir on the subject was the result of years of painstaking observation. Addison had not so exact an idea of the very special nature of the disease as we now have, as he associated it with "idiopathic anemia" and he believed that any disease which involved the structure of the organs might be productive of the symptoms he himself styled the disease *metasma suprarenale;* the term bronzed skin also came into use, and the term cutis acnea may be found in Oliver Wendell Holmes' *Poet at the Breakfast Table.* Addison's discovery was by no means universally accepted. Large treatises in Germany and France were written in disproof of its existence although Trousseau gave it the name of Addison's Disease. In Edinburgh, Addison's Alma Mater, Hughes Bennet and other professors would not acknowledge it but endeavored to explain it away.

Addison's fame in future years will rest upon this discovery and upon his writing, but during his lifetime they added little to the reputation which he then enjoyed. This, which was very great, was owing entirely to the personal influence he exerted over his pupils and those who came into contact with him.

His original work on chest disease did not appeal to students, and his memoir on suprarenal disease did

not appear until near the close of his career. The secret of his position was the personal power he possessed, greatly superior to that which Bright could ever claim, and equal, if not greater than, that of Sir Astley Cooper. For many years he was the leading light of Guy's so that every Guy's man during the thirty or forty years during which he taught was a disciple of Addison, holding his name in the greatest reverence, and regarding his authority as the best guide in the practice of the medical profession. Addison was not learned in the history of medicine; whatever he said was his own, and his sayings were eminently practical. He was dogmatic in his sayings and thus students accepted as pure gospel every word which flowed from his lips.

The force of his words was enhanced by his mode of delivery and by the presence of the man himself. Addison was of good height and well made, stood erect, with coat buttoned up very high, over which hung his guard and eyeglass. He wore a black stock with scarcely visible shirt collar, and this further elevated his head. He had a well proportioned good head, with dark hair and side whiskers, large bushy eyebrows and smallish dark eyes, nose thick as were also the lips which enclosed his firmly knit mouth. His features were not refined, but belonged to a powerful mind, and showed no trace of any kind of sentiment. His penetrating glance seemed to look through one, and his whole demeanor was that of a leader of men, enhanced by his somewhat martial attitude. He was feared rather than loved by the students while at the same time he was most implicitly believed in.

It was difficult to conceive a better teacher. His lectures were of a very high order, extempore, couched in good language which amounted occasionally to true eloquence. His clinical lectures were especially excellent, as he never failed to thoroughly unfold the case which he was discussing, and so, arguing both from positive and negative reasons, he placed the diagnosis on a sure foundation. His examination of the patient was of a most complete character. He never reasoned from a half discovered fact but would remain at the bedside with a dogged determination to track the disease to its very source irrespective of the time it might take to do so. He was surpassingly skilful in auscultation of the heart and lungs.

Perhaps, as a clinical investigator Addison has never been equalled and to those who knew him best his power of searching into the complex framework of the body and dragging the hidden malady to light appeared unrivalled. However, in one respect he found little favor with the medical men of his day and committed an unpardonable fault in the eyes of the patients. If he did not see his way to the use of a drug he would not give it. He was called in on one occasion to an obscure case of abdominal disease. Addison spent a long time in unraveling it, and finally pronounced it to be cancerous disease of the peritoneum. He discussed it with the patient's medical attendant, saw the friends, and was departing when he was called back and reminded that he had not written a prescription. Addison asked the medical man what he was giving, and he said magnesia mixture; to which Addison replied, "a very good medicine; go on with it." In the spring of 1860 Addison was compelled to retire from his hospital duties by a threatening of brain disease and went to Brighton for the benefit of his health. There he died, June 29, 1860, aged sixty-seven. A marble tablet in the chapel of Guy's Hospital records his merits, and one of the wards of the hospital is named Addison Ward.

Addison was decidedly one of the great men of medicine. He was an original thinker and worker but at the same time was eminently practical. His clinical observation was remarkably acute and as a diagnostician he has had few superiors. These gifts combined with ready speech approaching eloquence made of him a model teacher and he helped to raise the standard of the medical school of Guy's to an appreciable extent.

The Story of a Great Consultation: Jerome Cardan Goes to Edinburgh.—Dr. Charles L. Dana (*Annals of Medical History,* June, 1921) considers Cardan as typical of his time—"an accessible mirror of the medicine, learning and life of the university world of the sixteenth century." He tells the story of the learned physician's journeyings from Pavia, where he had just resigned the professorship of medicine at the university, to Edinburgh in response to an urgent call from the personal physician of the Archbishop of St. Andrews to treat the latter who was suffering from a very severe and prolonged asthmatic condition, due to "a cold moist brain." No abstract can do justice to the clever, humorous and interesting manner in which Dr. Dana treats his subject. The article, from beginning to end, is delightfully written.

Cardan, with five attendants, began his journey on February 23, 1552, and reached Edinburgh on June 29th. His route was over the Simplon Pass to Lyons, thence to Paris, then called Lutetia, where he met in consultation the famous Jacobus Sylvius and John Fernel, who discussed the troubles of the Archbishop, Cardan wisely keeping silent and venturing no opinion. The thing that seems to have impressed him most in Paris was a unicorn horn shown him by the physician to the king in one of the churches. At about this time he had drawn up a contract with the Archbishop, but it was then destroyed as being unnecessary between a physician and an honorable patient. That this was a perfectly safe procedure in those days is shown by the fact that, at the end of his course of treatment, Cardan was given a much larger sum than the original arrangement called for, and many valuable presents besides.

He found Paris very dirty as to streets, smelly, and with a dense population. He arrived in London in June, and found England "immensely cold . . . the grass full of worms, and the sky darkened with crows." He stayed only a few days and left for Edinburgh, where he remained until September 12th. "I doubt if he had a very good time," writes Dr. Dana. "Cardan's chief amusements at home were gambling, music and fishing, being most expert in the first. . . . He wrote a very good book advising against it but instructing in the practice. Cardan did not like politics or theology, or massive attacks on food and drink, which were the standard diversions of the time." . . . He did not begin his

treatment of the Archbishop for forty days after his arrival, prudently allowing the personal physician to carry out the treatment prescribed in Paris by Sylvius and Fernel. The Archbishop grew worse, Cardan explained, and he was commanded to go ahead with his own method.

Cardan believed that the great man's brain, instead of being cold and damp, was hot and dry, causing humors distilled in the stomach to rise into the brain, and that his food was turned into phlegm, which passed into the bronchial tubes, causing cough, expectoration and dyspnea. "As a matter of fact," says Dr. Dana, "the bishop was a great eater and drinker, and took no exercise; he worked hard, kept irregular hours, and was not shy with the ladies. Practically, Cardan put him on a Weir Mitchell rest cure. . . . He rose at 8 o'clock and took, one day in eight, a shower bath—the first ever taken in Scotland. Then he took a quiet walk in a shady place, chewing a little mastic, the sixteenth century substitute for pepsin gum. This caused expectoration and purged the brain. At 9 o'clock he had breakfast, consisting of liver with a little ginger, and some bread, with two ounces of white wine. After this he could have a little chicken and a little more wine. After breakfast he rested and amused himself. From 12 to 4 he was allowed to attend to his business, but was forbidden to write letters with his own hand. At 4 he went out for an hour's ride on horseback. He then, sitting or reclining, was allowed to give audience to those who wished to see him. He had supper at 7 o'clock which was like his breakfast, but opened with a sixteenth century cocktail consisting of a teaspoonful of pure honey. He was to go to bed at half past eight and secure ten hours of continued sleep. As specialties in the diet, he was recommended turtle soup, snails, barley water, and chicken broth." A few suggestions as to the Archbishop's social hygiene were added. About the only medication the patient received was a blistering of the coronal suture, and a mixture of milk and water with two grains of elaterium poured through the nose, this being done on an empty stomach. The bishop was forbidden to sleep on a feather bed, made to use a linen pillow, told to comb his head every morning with an ivory comb, and to give his extremities a vigorous rubbing. He was also advised to purchase a clock. He was given as a laxative preserved peaches and sugar of violets, had to drink a quart of milk a day, and to take as a fattening agent two ounces of sugar water dissolved in the broth of a young pig. "All this, it seems to me today," writes Dr. Dana, "was very good and modern treatment—no bleeding, no purgations, no polypharmacy." . . . The bishop began speedily to improve. When Cardan left, his patient promised to write in two years telling of his condition. "Cardan had the follow up system of today." He wrote out for his patient a document of twenty folio pages giving theory and treatment, and an outline of seven pages. Both these documents are printed in his *Opera Omnia,* published in 1563.

On his way home, he visited at the court of Edward VI, then fifteen years old, and was greatly impressed by the goodness, charm, learning and intelligence of the young king. The boy was delicate and Cardan was asked by the scheming English nobles, not to treat the young monarch, but to foretell, through astrology, the time of his death. Cardan saw through their plottings and made out a horoscope giving him twenty more years. But Edward died the following spring, perhaps poisoned.

Cardan was a great mathematician as well as a doctor and was responsible for introducing algebra into the schools of Europe. "Doctors were often mathematicians in those days. When Sancho Panza fell off his mule, he cried out, 'Send for an algebraist!'" On his return to Italy, Cardan visited several famous mathematicians and other noted men of the day. He finally reached Milan on January 3, 1553, after an absence of 310 days. His autobiography, *De Vita Propria,* has been called one of the three greatest in literature, the other two being those of Cæsar and Rousseau.

"Cardan was sensitive, affectionate, introspective, imaginative, superstitious, humorous, inclined to ideas of selfreproach, with high ambition and hypomanic industry. Concerning his own weaknesses, he admits that he was always inclined to sensuous pleasures. Of these, he adds, the worst and greatest was his love of music. In his book, he becomes very melancholy over this defect in his morals. He was not of the woman pursuing type, but he wrote some advice to his sons about love: "Love is a pleasant torture, a noble folly and a madness of a unique kind. It is the fruit of youth, the crime of age, to love and to be wise belongs to the gods alone.' . . .

"His career and writings reflect what was best in the art, practice, learning and ethics of the day. In his art he was not behind later centuries. In his ethics he was abreast even of those today."

Decline of the Doctrine of Spontaneous Generation.—The decline of this doctrine may be dated from the observations of Francesco Redi upon flies and maggots in the seventeenth century. Until Redi's time—1626-1699—it was generally believed that flies were spontaneously generated in putrefying meat. He placed meat in glass jars, over which he placed netting, then watched to see what would happen: flies smelling the meat in the jar, alighted upon the gauze, where they sometimes deposited their eggs or larvæ. No maggots ever occurred in the meat as long as the flies were prevented from getting at it. Redi came to the conclusion that the maggots were the half developed progeny of the flies, and that flies were not developed spontaneously. —*Fighting Foes Too Small to See.*

Egyptian Medicine.—The earliest known physician was Imhotep, a medical demigod, the Æsculapius of the Egyptians, who flourished about 4,500 B.C. The pharmacopœia of the Egyptians was exceedingly rich; one papyrus mentioned over seven hundred different drugs; hygiene reached a high stage of development. Medicine was associated with magic, and was a priestly occupation. The earliest recorded use of secretions and parts of the animal body as medicine is to be found in the medical papyri. While there are isolated fragments, such as the pyramid inscriptions, most of our knowledge of Egyptian medicine is obtained from the medical papyri.—*Annals of Medical History.*

Editorial Articles

UNCONCEALED WEAPONS

The concealed weapon is forbidden by law, though it is not nonexistent; the unconcealed weapon is greatly in evidence and carried by multitudes. The concealed weapon always was under the control of the user—at any rate, it never controlled the user, but the unconcealed weapon is the more dangerous in that it always partly controls its manager. A revolver may go off accidentally in a few cases, but the driver of an automobile takes the risk many times a day of running down the pedestrian, or other driver, who does not happen to avoid him.

The new weapon is especially dangerous on account of its size. It is as big as a small house and is, therefore, the more unmanageable and the more difficult to avoid. The new weapon changes the nature of the wielder. By virtue of driving an auto he becomes another man and has unavoidably another attitude toward his fellows. This is well illustrated by the example of a countryman of our acquaintance, a middleaged farmer, who was, for years, shy of the new vehicle and cursed it roundly for running down his chickens when they strayed upon the road. He was finally persuaded by a friend from the city to take a ride with him in his car, and about the first words he uttered were, "Why don't the farmers keep their damned chickens out of the road!" There you have it. The pedestrian's attitude had been reversed and the new attitude was that which produces destruction of life. And since the autoist's attitude is, of necessity, that of a man who is not in complete control of his weapon and cannot check it in an instant, the pedestrian, whether chicken or man, should keep himself out of the way or be damned, if not run over.

The problem is not to be solved by educating either pedestrian or driver. Some defensive device, some autostop device, to be carried by the pedestrian in selfdefence against the weapon propelled assailant, may be invented. It may be necessary to build separate ways for autos. If this new weapon were one used in war, of course all the inventors, backed by unlimited funds, would be hard at work upon the problem of checking its destructiveness, but, though, as Sir Arthur Newsholme said, "Peace has its horrors as well as war," we think little of our annual slaughter of innocents which would make many "great" battles sink into insignificance.

At least we could at present make the crimes of accidental wounding or killing by this huge unconcealed engine punishable by forbidding, in future, the driver ever to drive a car or, better, to make him a pedestrian for all his days. It would seem but a slight addition to the ordinary fines imposed, but it might help as a deterrent where there seems no other help in sight.

THE FUTURE OF PREVENTIVE MEDICINE

Stress is being constantly laid by leading members of the medical profession, and by men of science generally, on the point that in the conquest of disease preventive medicine will play the foremost part. The last great exponent of the medical art publicly to declare his adherence to these views was Sir David Bruce, himself instrumental in conquering Malta fever and in severely checking the aggressions of sleeping sickness. As president of the British Association for the Advancement of Science, which met in Toronto on August 6th and following days, Sir David Bruce in an eloquent address dealt with recent advances in knowledge of the treatment and prevention of disease. He said that in estimating the cash value of the prevention of disease it was calculated that the direct loss in England and Wales from sickness and disability amounted, at least, to £150,000,000. In the United States, with a much larger population, the loss was put down at £600,000,000 a year. In view of these facts, medicine must change its strategy, and instead of awaiting attack must assume the offensive. He pointed out that in this offensive campaign against disease that it must no longer be said that a man was so sick that he had to send for the doctor. The medical practitioner of the future must frequently examine the man while he is apparently well, in order to detect any incipient departure from the normal, and to teach and urge modes of living conformable to the laws of personal health, and the public health authorities must see to it that the man's environment is in accordance with scientific teaching.

He paid a fine tribute to Pasteur, who revolutionized medicine and its practice, declaring that it was his discovery of the germ theory that lifted medicine out of the region of vague speculation and set its feet firmly on new ground as an experimental biological science. The concluding part of Sir David Bruce's address, in which he considered the question of dietetics, was perhaps of the most immediate interest, taking into account the rôle now ascribed to diet in the production and consequently in the prevention of disease. In the consideration of diet he uttered a salutary and apposite warning, that as our knowledge was constantly increasing, our ideas about things were constantly

changing, and therefore what was looked upon today as absolute, immutable truth, was seen tomorrow in the light of some newer knowledge to be but a crude beginning. It was thus with the teaching concerning what constituted a complete and healthy diet. He discussed that much debated subject, the comparative freedom from disease of the untutored savage or primitive man. Until civilized man came into the regions in which dwelt the savage, living on the natural fruits of the earth and the chase, he knew no deficiency diseases. It was only when man began by artificial means to polish his rice, whiten his flour and can his food and vegetables that trouble started.

Housing conditions and food conditions in towns, as a rule, predispose to certain diseases and improvement in both directions should undoubtedly prevent disease to a considerable extent. In civilized countries the future of medicine lies largely in prevention and not less so in tropical countries. Malaria, for instance, can be much more effectively prevented than cured and so with all the insect borne diseases. In civilized lands it is the deficiency diseases which call chiefly for prevention, while in tropical countries it is the insect borne diseases.

As Sir David Bruce said, "The advance of knowledge in the causation and prevention of disease is not for the benefit of any one country, but for all, for the lonely African native, deserted by his tribe, dying in the jungle of sleeping sickness, or the Indian or Chinese coolie, dying miserably of beriberi, just as much as for the citizens of our own towns." In the prevention of disease a great deal will be effected by the better care and treatment of the pregnant woman, both before and after parturition, and the better care of infants and children.

It is in this branch of preventive medicine that the greatest expectation of quick results lie. Improved antenatal care, efficient midwifery under favorable conditions, and skilled postnatal care of mother and child will not only decrease mortality and morbidity but will enchance the chances of the rising generation physically and mentally. Although it is true that the future of medicine rests largely in prevention, there will be always plenty of scope for treatment, remedial and curative. In fact, the trend of the medicine of the future should but widen the sphere and enlarge the opportunities of the medical man. Public health measures have already eliminated certain epidemic diseases and are on the way to eliminate others in civilized countries and in the future better housing, improved domestic and personal hygiene, suitable and adequate diet will no doubt go far towards benefiting the general health. Utopia is not yet in sight and probably will never be reached, but the future of preventive and remedial medicine is hopeful.

MORE HEALTHY YOUNG WOMEN

Young women, at least those of the well to do class, are considerably more healthy than their sisters of a generation or so ago, and those of the working classes have also improved in health. This improvement in health is largely due to the different mode of life which girls of this era lead from that a few decades back. This improvement is even more marked in Great Britain than in this country. In the former land the Victorian girl was not athletic, did not play tennis, ride on horseback, swim, or run. In fact in those days it was not "good form" to do anything of the sort. The girl of the period took very little out of door exercise, was pale of complexion, it was not well bred to be of a ruddy countenance. She lived indoors mostly, did a great deal of fancy work, read sentimental novels, and for exercise played a placid game of croquet. Her manner of living is well depicted in the novels of Jane Austen.

But, *nous avons changè tout cela,* and now the pendulum has swung perhaps too far in the opposite direction. The modern girl emulates the male youth in exercise and sport. She plays tennis, golf, and indulges in athletic exercises of every description. In many forms of sport she not only takes part but even excels. She shoots and fishes and goes into the heart of Africa and off the beaten track in all parts of the world in pursuit of big game. *Pari passu* with these changed methods of living the young woman of the present day is amazingly healthy and anemia, the outstanding complaint of thirty or forty years ago, is almost at the vanishing point.

Dr. J. M. H. Campbell, in the August issue of Guy's Hospital report, sets out to show that chlorosis has decreased enormously since 1898 and seems to be becoming extinct. The lessened prevalence of this condition is sometimes attributed to improved conditions of housing, feeding, and to a higher standard of life in all respects. It used to be said that chlorosis was caused by hardship and poor feeding. Sir William Osler held that it chiefly occurred among ill fed, overworked girls of large towns, who were confined all day in close badly lighted rooms, and that lack of proper exercise and fresh air and the consumption of improper food were important factors. However, Dr. Campbell, after a close investigation of the subject, concludes that a study of the cost of living and of unemployment does not suggest that hard conditions of life and poor food are the main factors in producing chlorosis, though both appear to have a slight influence on its incidence.

With regard to occupation it is generally agreed that the condition is especially common among domestic help. In Campbell's series there were notes on the occupation in fifty-three cases. In thirty of these the patient was a household servant and in five

others a children's nurse or housemaid. In nine others the occupation was given as housework. In only nine were the patients employed in other occupations, such as laundry workers, clerks, housecleaners or packers. It certainly was not the diet which was chiefly responsible for the prevalence of chlorosis among domestic help nor was it the housing, for, as a rule, girls in such situations are better fed and housed than those who work in factories and so on.

After considering various possible hypotheses to account for this change, Campbell records his opinion that the disappearance of chlorosis is a very real change, and that it is mainly due to improved conditions of employment, allowing more opportunity for fresh air and exercise. He goes on to say that it should be possible to test such a hypothesis by comparing the amount of chlorosis among the class of Turkish women living in close confinement and among the women of the other Balkan States who live under similar conditions.

It has also been suggested that the disappearance of chlorosis was due to an inborn rather than an environmental change, but it seems, interesting as an evolutionary theory is, that the change is due more to different environment and a more healthy mode of living from all points of view. It may be pointed out that the British figures relating to chlorosis showed a decrease from 6.6 per cent. cases in 1898 to 1.5 in 1917. There is also good evidence that it has diminished in this country and Sweden, and verbal evidence of a similar change in France and Austria. Perhaps, therefore, the change is almost world wide, though not universal.

Every day now research shows that the influence on health of good housing and light can scarcely be overestimated and especially of light. Rickets and tuberculosis, the first named, of course, in particular, are favorably affected by light. Diet is an important factor but it appears as if environment is even more important. If light and good housing are eliminating chlorosis, why, if carried into effect on a far wider scale, should not tuberculosis and rickets be eradicated?

THE OPERATIVE TREATMENT OF CHRONIC GASTRIC AND DUODENAL ULCERS

In the field of surgery no subject of late years has been discussed so freely or written of so widely as surgery of the stomach and the duodenum. It must be borne in mind that surgical intervention in gastric or duodenal ulcer is of comparatively recent date, and the great mass of literature bearing on this subject testifies to the importance of the question and to the intense interest manifested in it.

Suturing perforating ulcer of the stomach was the first step in the more or less elaborate operations nowadays performed for a similar purpose, and Dr. Fred B. Lund, of Boston, who first published a report on the method in this country, in the *Boston Medical and Surgical Journal,* January 11, 1900, in the issue of the same journal for August 7, 1924 gives a brief and critical review of the surgical treatment of chronic ulcer of the stomach and duodenum from then up to the present time. He points out that the first successful operation on this continent was done by Dr. Atherton, of Frederickton, an account of which may be found in the New York *Medical Record* in 1895. The first reports of operation in cases of perforating ulcers began to be published in 1893 in the London *Lancet,* the oldest one on Dr. Lund's list is in the *Lancet,* vol. 1, p. 4, 1893. For demonstrating that chronic ulcer of the stomach would heal after gastroenterostomy the profession owes as much to Mayo-Robson and Moynihan as to anyone, and in this country the Mayos and the late John C. Munro and others have done much to perfect our methods.

Dr. Lund traces the development of various surgical methods calculated to render an operation effective and safe and concludes that the safest and simplest operation in the hands of most surgeons is gastroenterostomy with the clamp. In fact, in his opinion, such persistent attention has been given to perfecting this operation that it has become very simple and safe, at least in the hands of men who have practised it. Dr. Lund gives valuable advice as to the details of the technic and gives his reasons thus for the use of the clamps, because soiling is avoided, and the accurate apposition of the tissues is made so much simpler and easier, as the surgeon is not disturbed during operation by a rush of blood and the necessity for placing ties. He further points out that the one danger of the clamp, that of secondary hemorrhage after the operation, may be avoided only by the most careful and accurate placing of every suture. Indeed, the writer emphasizes forcibly the need for using proper sutures and doing the suturing in the most careful and painstaking manner.

Attention is drawn to another point, that in the early days a large proportion of the poor results from gastric surgery was due to faulty diagnosis. The x-rays have done much to make diagnosis more or less certain, and modern, careful perfected technic have done the rest. A warning is given that an ulcer at the duodenum should never be excised without a gastroenterostomy being done. Dr. Lund declares himself averse to resecting the ulcer bearing area of the pylorus and duodenum; he does not fear cancer at the pylorus as in his experience cancer has never

leveloped on the site of a primary ulcer. With regard to ulcers on the lesser curvature it is another story. They are not so apt to be benefited by drainage of the stomach and therefore by gastroenterostomy as is the case with ulcers at the pylorus. Their excision is bloody and difficult and for such cases Balfour's procedure is advised.

While Lund agrees with Mayo that the field for partial gastrectomy is greater in ulcers of the stomach than in the duodenum, in his experience the ulcers at the pylorus or first on the gastric side behave as well after gastroenterostomy as those of the duodenum. He emphasized the fact, too, that to resect safely an ulcer going well down to the duodenum one must be able to get at it easily. When the stomach cannot be drawn pretty well outside the abdomen resection is unsafe. Dr. Lund has had a long and wide experience in the Municipal Hospital at Boston and his conclusions on a still much debated question are valuable.

Especially interesting are his views as to the great unlikelihood of cancer appearing on the site of a primary ulcer on the pyloric side of the stomach, views contrary, perhaps, to the majority of abdominal surgeons. It may also be noticed that radical surgery is being more widely done in Central Europe on ulcer of the stomach and duodenum than elsewhere.

It appears that in Great Britain, although gastroenterostomy is extensively employed other methods are largely used. Some of the leading surgeons of London are not in favor of gastroenterostomy. It is evident that the last word has by no means been said yet with regard to the surgical treatment of chronic ulcer of the stomach and duodenum.

THE PROBLEM OF LEPROSY

While leprosy is not perhaps of direct interest to the medical profession of this country, it is estimated that the number of persons suffering from this disease here varies between 146 and 1,000. It is of interest because it is a malady of great historic concern and at the present time there is computed to be in the world, mainly in Asia, some two million two hundred thousand lepers.

In China, where leprosy is most prevalent, there are in the neighborhood of a million lepers. Next comes India with 500,000 lepers and Europe, including South Russia, has 7,044. In Africa there are at least half a million. In some of the Pacific Islands it is fairly prevalent, and some of our public health men have had considerable experience with the disease. India contains about one fourth of the leper population of the world, and it is in India that the most thoroughly organized research into, and treatment of, the disease on a large scale is being carried on and where consequently the best hope of its ultimate eradication may be looked for. The encouraging part of the leper situation in India is largely due to the fact that Sir Leonard Rogers, who is one of the most brilliant workers in the field, pursues his investigations in that country and has initiated and is developing research into its cause and preventive, remedial and curative treatment.

On March 16th, last, Sir Leonard Rogers read a paper before the Royal Society of Arts in London on recent advances toward the solution of the leprosy problem. The paper had an important bearing on questions of child welfare and education in those countries, mostly of a humid tropical or semitropical climate in which this dread scourge prevails. It may be recalled that some sixty years ago, high medical authorities held that the disease was not contagious nor communicable to healthy persons by contact with the disease and in accordance with this ruling, laws compelling or sanctioning measures of segregation were generally repealed. However, it has now been established beyond question that leprosy is a communicable disease for which isolation of the infective cases is the only certain means of preventing its spread. The experience of Norway in this direction is sufficiently convincing proof of its efficacy when adequately and persistently carried out. And therefore it is a serious question as regards child welfare and education in countries where the disease is prevalent.

Also there seems to have been abundant proof that the treatment associated with the name of Rogers ameliorates the condition of the patient, and, moreover, renders the disease less infective. Chalmoogra and other oils, but chiefly the former, have been employed with success. Another point worthy of attention is that the children of lepers do not necessarily inherit the taint. Yet such children exhibit especial susceptibility to the contagion. Hence children and adolescents should never be allowed to live under the same roof with a leper and infants of leper parents should be removed from them as soon as possible after birth. Rogers declared that long experience of India and elsewhere has proved that if the children of lepers are brought up apart from their parents, they remain free from the disease and can safely marry when grown and their children will not become lepers. He is of the opinion that if infection of the young could be prevented leprosy would rapidly decrease.

The Mission to Lepers, which devotes itself to the problem of segregation and of maintaining homes for the untainted children of lepers and which has been working in India for longer than half a century, has been doing magnificent work. It works in close co-

operation with government agencies, research authorities and other workers in the same field, and recently has been establishing the leper colony system in suitable areas so that a cottage system can be utilized for married patients with the advantages of home life, although, of course, healthy children must be removed from their parents at the earliest age.

Rogers emphasized the point that the greatest obstacle to the effective carrying out of segregation is the difficulty of isolating the early cases, which will continue to form foci for the spread of the disease as long as they have everything to lose and nothing to gain as heretofore. But he went on to point out that now that a treatment is available both for improving their condition and also rendering the disease far less infective by destroying so many of the causative bacilli, the situation is completely altered and already for the first time in the long struggle against leprosy in the Sandwich Islands numerous early cases have come forward in the more curable stages and asked for the new treatment.

A similar important change in the outlook is taking place in India and China. It may be said that hope for the future control of leprosy is encouraging. It would be premature to make any definite statements so far as Rogers's experience with chalmoogra, codliver and soya bean oils is concerned. A few early cases have not remained free from all signs of the disease for at least five years; while the infectivity of the disease is greatly reduced or completely removed in successful cases. It is interesting to note that a great deal of the work among lepers is done by medical missionaries and the nursing is done by missionary nurses; for the most part, white men and women.

A very great obstacle to the successful care and treatment of lepers is that few white medical men or nurses will consent to bury themselves in a hospital the inmates of which are Asiatics suffering from leprosy. It certainly says a great deal for religion that white medical missionaries and nurses will do so for the uplift of humanity spiritually and physically and for science.

It would certainly be invidious when discussing the problem of leprosy not to refer to the work done by several of the United States Public Health Service men who have made perhaps the most thoroughgoing investigations into the origin of and the treatment of the disease which have ever been made. But the immense resources of clinical material in India and the efforts being made by the Government and missions to prevent, successfully treat and control the malady render that country at the present time the centre of interest as regards leprosy and the country in which the final solution of the problem is most likely to be reached.

EDUCATION IN BUSINESS IDEALS, THEORY AND PRACTICE

The newer educational ideals combining training and actual practice in business and professional life are being tried out in a most interesting way at Antioch College in Ohio. This college combines in its six years course a general college education, special vocational training, and apprenticeship to practical life. Required courses give the student training in physical hygiene, in economic sense, and in the usual academic studies. Vocational courses help him to decide upon the vocation for which he is temperamentally best fitted, such as engineering, business administration, journalism, home and institutional management, and work along educational lines. Administrative ability in the individual is cultivated rather than a specialized technic. Halftime practice work in alternate shifts of five weeks with a number of prominent local business, professional and industrial firms helps to develop his sense of responsibility, and to enable him to decide upon and prepare for his particular vocation. The aim of the college is to narrow, through everyday methods of common sense and good will, the gap between theory and practice, thus bringing about a balanced development of character, intelligence, and power. "If we can develop an honest desire to work out sound business principles, and an honest effort to put them into practice, worth while results will follow," says a recent bulletin of the college. "Repeatedly men are torn between the desire to live by the finest ideals and the necessity for meeting practical issues in a practical manner. He is an educated man who, through experiencing this stress, has learned to harmonize such conflicting demands. Part time work at Antioch will accomplish its highest aim if it brings about that result." The Antioch business code is stated as follows: "Sound business is service which benefits all the parties concerned. To take profit without contributing to essential welfare; to take excessive profit; to cater to ignorance, credulity, or human frailty; to debase taste or standards for profit; to use methods not inspired by good will and fair dealing; this is dishonor. Whenever I make or sell a product or render a business service, it must be my best possible contribution to human well being."

News Items.

Scholarship for Graduate Study.—Scholarship on the Oliver-Rea Foundation for graduate study in medicine are available at the New York Postgraduate Medical School and Hospital. Inquiries should be addressed to the Dean, 301 East Twentieth Street, New York.

First Harvey Lecture.—Professor S. T. L. Sörensen, Director of the Carlsberg Laboratories, Copenhagen, Denmark, will deliver the first Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, October 4, 1924. His subject will be The Solubility of Sodium.

Postgraduate Medical School Lectures.—An announcement is made of lectures to be given at the Postgraduate Medical School, Wednesday afternoons at five o'clock, to which all practitioners of medicine are invited. The first three of these lectures are scheduled as follows: October 8th, Dr. Arthur F. Chace, Diagnosis and Treatment of Uric Acid Conditions: October 15th, Dr. Roger H. Dennett, Treatment of Diarrhea in Children; Dr. John I. Moorhead, Infections of the Hand.

Lister Medal.—The Lister medal for distinguished contributions to surgery has been awarded by the Royal College of Surgeons of England to Sir William Watson Cheyne.

Sociology at University of Wales.—Dr. G. Arbour Stephens, of Swansea, Wales, is endeavoring to encourage an interest in practical sociology at the University of Wales, and the Academic Board has recommended that various lectures be delivered.

Research in Electronic Energy.—A laboratory has recently been built at Alpine, New Jersey, for research work in electronic energy, to be carried on by Dr. J. Clawson Burnett, and Mr. J. H. Hallberg, a prominent electrical engineer.

Dispensary Social Service.—The Executive Committee of the Hospital Social Service Section of the Associated Out-Patient Clinics of New York, has published in pamphlet form a report prepared by Louise Stevens Bryant, Ph.D., on a study of social service in fifty-one dispensaries of Greater New York.

Police Emergency Hospital.—An x ray clinic and emergency hospital is soon to be opened in Police Headquarters, New York, for the use of members of the force and their families. Donations making the clinic possible were given by Mr. August Heckscher of New York and Mr. Frank Phillips, of Omaha, and surgical instruments and equipment were provided by Dr. Ernest Fahnestock, honorary police surgeon. Dr. Patrick J. Murray, chief surgeon, will be in charge.

Postgraduate Courses.—The following postgraduate courses are scheduled for New York: traumatic surgery, orthopedics, and rehabilitation, by the New York Postgraduate Medical School and Hospital; surgery, by the New York Homeopathic Medical College and Flower Hospital; skin diseases and cancer, by the New York Skin and Cancer Hospital; diseases of the heart and arteries, by Beth Israel Hospital; regional anesthesia, by New York University and Bellevue Hospital Medical College; pediatrics, by Columbia University and Mount Sinai Hospital.

Cooperative Store For Diabetic Patients.—A cooperative store for the sale of insulin and other supplies necessary for diabetic patients has been opened in Seattle, Washington, in space given by the Virginia Mason Hospital, which has also provided clerical supervision. The store will be open three hours a day. No profit will be made on any sales, and the price of the articles sold has been adjusted on a sliding scale, from full price to full charity. An endowment by a group of Seattle philanthropists, at the suggestion of Dr. Elliott P. Joslin of Boston, who recently lectured in Seattle, has made this benefaction possible.

Gifts and Bequests to Hospitals.—The following bequests are included in the will of the late Solomon C. Guggenheimer:

To the Federation for the Support of Jewish Philanthropic Societies of New York City, $40,000. To Mount Sinai Hospital, to endow a bed to be known as the S. C. Guggenheimer bed, $7,500. To the Lenox Hill Hospital, $2,500. To the Hudson Guild of the City of New York, $2,000. To the New York Association for Improving the Condition of the Poor, $2,500. To the Guild for Crippled Children of the Poor of New York City, $1,500. To the Children's Aid Society, for the use of the Newsboys' Lodging House, $2,000. To St. Luke's Hospital, $2,000. To the National Jewish Hospital for Consumptives of Denver, Col., $2,500. To St. John's Guild of New York City $1,500. To Roosevelt Hospital $2,500.

Personals.—Dr. Henry B. Young, of Burlington, Iowa, a former president of the state medical society, has been honored by a banquet in celebration of his fiftieth year as a medical practitioner.

Dr. Fred M. Smith, of Chicago, has been appointed professor of internal medicine and head of the department of theory and practice of medicine, at the medical school of the University of Iowa. He will succeed Dr. Campbell P. Howard, who has accepted a professorship of medicine at McGill University, Montreal.

Dr. John M. Frankenburger, of Kansas City, has been appointed superintendent of the Kansas City Hospital, succeeding Dr. William L. Gist, who has resigned.

Dr. Louis F. Arensburg, of Uniontown, Pennsylvania, has been elected commander in chief of the Grand Army of the Republic.

Dr. McCluney Radcliffe, for many years on the staff of the Wills Hospital, Philadelphia, has resigned as surgeon; he will be succeeded by Dr. Thomas A. O'Brien.

Community Health Work.—Due to lack of funds, the Community Health Association of Boston has been been compelled to release about fifty nurses and part of its executive staff. It is estimated that about 480 fewer persons each day can be cared for.

Hospital Ship.—The steamship *Arras* has been fitted up for a hospital ship by the Canadian Department of Marine and Fisheries and is now on duty on the Grand Banks, to provide medical aid and hospital treatment for fisherman, and in general for sailors on Canadian and Newfoundland boats that may be in that vicinity.

British Medical Association Prize Winners.—Dr. Edward Mellanby, professor of pharmacology at the University of Sheffield, has been awarded the Stewart prize, for discoveries on the relation between rickets and deficient diets, and Dr. Henry Britten Brackenbury has been presented with a gold medal for distinguished services to the association and the medical profession.

Research at Yale University.—Psychological research at Yale University has been provided for by a five year contribution from the Laura Spelman Rockefeller Memorial. This will be directed to the study of fundamental problems of behavior, and the training of personnel for subsequent studies. Roswell Parker Angier, Ph.D., professor of psychology at Yale, will be chairman, and Robert M. Yerkes, Ph.D., formerly of the National Research Council; Raymond Dodge, Ph.D., formerly professor of psychology at Wesleyan University, and Clark Wissler, Ph.D., of the American Museum of Natural History, will join him in the research.

Society News.—The thirty-second annual meeting of the Association of Military Surgeons of the United States will be held at San Antonio, Texas, November 13 to 15.

The annual meeting of the Medical Society of the State of Pennsylvania is to be held at Reading. Dr. William Allen Pusey, president of the American Medical Association, will be one of the speakers. The Berks County Medical Society, which has its own home in Reading, will provide entertainment.

The National Medical Association, an organization of negro physicians, recently held its annual meeting at Newport News, Virginia. Dr. Michael C. Dumas, of Washington, D. C., was elected president, and Dr. Walter G. Alexander, of Orange, New Jersey, as president-elect.

A conference including meetings of the Medical Association of the Southwest, the American Child Health Association, and the Kansas City fall clinical conference, will take place from October 13th to 16th. The Hon. Herbert Hoover, Mr. George E. Vincent, and Surgeon Generals Cumming and Ireland will speak. A tablet will be unveiled at Bell Memorial Hospital in memory of Liuet. William T. Fitzsimmons, of the Medical Corps, U. S. Army.

The Medical Women's National Association has elected Dr. Anna E. Blount, of Oak Park, Illinois, president; Dr. Katherine C. Manion, Port Huron, Michigan, president-elect; Dr. Elizabeth B. Thelberg, Poughkeepsie; Dr. Frances C. Van Gasken, Philadelphia, and Dr. Mary E. D. Dennis, Los Angeles, vice-presidents; Dr. Blanche M. Haines, Lansing, Michigan, secretary; and Dr. Ethel D. Brown, New York, treasurer.

The Chicago Medical Society has elected Dr. Jeremiah H. Walsh, president; Dr. Malcolm L. Harris, president-elect; Dr. Clarence W. Leigh, treasurer, and Dr. Roy R. Ferguson, secretary.

Historical Medicine Congress.—The Fifth International Congress of the History of Medicine will be held at Geneva, July 22 to 27, 1925, under the auspices of the Medical Society of Geneva. The officers are as follows:

Honorary president: Sir D'Arcy Power, London; honorary vice-presidents: Dr. Capparon, Rome; Dr. D. Giordano, Venice; Dr. E. B. Krumbhaar, Philadelphia; Dr. Laignel-Lavastine, Paris; Dr. I. G. de Lint, Holland; Dr. A. Patry, Geneva; Dr. Charles Singer, London; Dr. Triest-Royer, Antwerp. President, Dr. Charles Greene Cumston. Vice-presidents: Dr. Ernest Wickersheimer and Prof. Andrea Corsini; general secretaries: Dr. A. de Peyer and Dr. Emile Thomas; treasurer, Dr. Jules Pallard.

A preliminary programme of the Congress will be issued on December 1, 1924, and may be obtained at the Office of the General Secretary, 20 Rue Général Dujour, Geneva, Switzerland.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

London, *August 6, 1924.*

MEETING OF THE BRITISH MEDICAL ASSOCIATION

The annual meeting of the British Medical Association, the ninety-second of the series, took place at Bradford. The representative body met on July 18th and discussed medicopolitical matters. The most important subject dealt with was the policy of the association towards voluntary hospitals. The discussion was animated and prolonged especially with regard to the question of taxing individual payments. Mr. Bishop Harman brought forward a motion to the effect that "where the board of a voluntary hospital receives contributions from members in return for or in anticipation of treatment, the members of the visiting medical staffs should receive recognition of their services, either in the form of an agreed honorarium or by means of a percentage of all such payments being passed into a special fund.

PROGRESS OF MEDICINE

Mr. J. Basil Hall, M.A., M.Ch.-Camb., delivered the address as president of the association on July 22d.

The title of the address was The Yesterday, the Today and the Tomorrow of Medicine. Mr. Hall said he thought that we were tending to lose our veneration for the past; perhaps we were too conceited about our present, and expected too much of the future.

Rudyard Kipling accurately described our modern mental attitude when he wrote:

> Wonderful little when all is said,
> Wonderful little, our fathers knew,
> Half of their remedies cured you dead,
> Most of their teaching was quite untrue.

But having written this, he paid them just tribute by adding

> Yet when sickness was sore in the land,
> When neither planet nor herb assuaged,
> They took their lives in their lancet hand,
> And oh, what a wonderful war they waged!
> Yes, when the crosses were chalked on the door,
> Yes, when the terrible death cart rolled,
> Excellent courage our fathers bore,
> Excellent hearts, had our fathers of old,
> None too learned, yet nobly bold,
> Into the fight went our fathers of old.

As a striking and curious commentary on the lack of veneration for and even of appreciation of the doings of their distinguished forerunners, by the modern product of medical science Mr. Hall referred to the fact that the circumstances of the birth of anesthesia had been almost forgotten. He retells briefly the tragic histories of Wells, Morton and Jackson and drew attention to the depressing truth that a short time ago it was proposed that a public memorial should be raised to Horace Wells in New York, but the municipal authorities declined to entertain the suggestion. This year also the Lister memorial block of the infirmary in Glasgow was being pulled down to make room for extensions and alterations. Was he not justified in saying that we were losing our veneration for the traditions of the past?

It might be argued that Glasgow was only a very small corner of the world, and Lister's memory would always be revered throughout the whole universe. Nevertheless, while we boasted today about all the wonderful feats we could and did perform, how many of us gave a thought to the poor little dentist who first conceived the possibility of bringing them within our range? Mr. Hall took a tilt against the idol and lure of specialism so rampant nowadays. He pointed out that there was one specialism which the layman frequently failed to appreciate at its true value, the specialism of general practice. There was the fear that clinical observation might become a lost art. Radiography and all the modern scientific methods were good servants but bad masters. He would take the stand therefore, that their present failing was an overconfidence in modern technic and a lack of appreciation of the value of that wisdom which could only be obtained by personal observation and experience.

FOOD VALUES

The question of food values was once again threshed out. Dr. John Orr, director of the Rowett Research Institute, Aberdeen, read a paper before the Section of Public Medicine and Industrial Diseases on The Importance of the Mineral Elements in the Maintenance of Health. He pointed out that during the past few years there had been a tendency to regard the evil effects of too exclusive a use of certain refined foodstuffs "as due chiefly or entirely to a deficiency of vitamines." Recent work, however, had shown that many of these evil effects might be attributed to the lack of correspondence between the mineral content of the diet and the mineral requirements of the body.

Of the fifteen chemical elements making up the body ten were mineral elements, and each of these was known to perform functions which could not be adequately performed by any of the others. All these minerals were continually being lost from the body in the excretions, and all were required as the constructive material of growth. He pointed out that the ordinary diet of the town dweller was deficient in both calcium and iron. It had been estimated that fifty per cent. of American dietaries contained less than 0.67 per cent. of calcium which was well below the standard of one gram a day. In Great Britain the average intake was likely to be even lower, because the average consumption of milk, usually the chief source of calcium in the diet, was twice as high in America as in Great Britain.

Dr. Orr said that mineral deficiencies could be corrected easily by including milk, green vegetables and certain fruits rich in calcium; milk, egg yolk, and cereals contained sufficient of the embryo, and outer part of the grain was rich in phosphorus. Green vegetables and egg yolk were rich in iron. The only certain sources of iodine were green vegetables and codliver oil. He insisted that in practice the adjustment of the mineral balance was of more importance than the inclusion in the diet of substances supposed to be rich in vitamines. Indeed experiments at the Rowtree Institute had shown that if a diet were properly balanced with regard to

minerals the vitamine content would be quite satisfactory also.

Dr. John Sinclair Manson of Warrington, discussed the common errors of diet in an urban population. These showed a lack of broths, soups, meat, potatoes, vegetables, and the increase of "snippety" meals, consisting of preserved meats, pickles, bread, margarine and tea. There was an increased use of canned meats, canned fruits and especially canned milk. The amount of tea consumed in families varied from three ounces to eight ounces of dry tea per head per week. Over the whole country the average per head per annum was said to be nine pounds of dry tea. Dr. William Savage, Medical Officer of Health for Somerset, made a strong plea for educational work in connection with food. Dr. H. Scarfield, Professor of Public Health, Sheffield University, said that the addition of chemicals and preservatives to food should be prohibited in some cases and declared in all.

Dr. Simpson, of Golspie, Scotland, said that in the Highlands of Scotland in the past twenty years there had been deterioration through diet. The crofter, formerly took porridge, milk and mutton broth. He was then worth looking at. Tea had now largely taken their place. A resolution was adopted recommending that a Standing Food Committee should be appointed to consider the question of diet.

GENEVA LETTER

(From our own correspondent)

GENEVA, *January 25, 1924.*

FAKE ADVERTISING

Among the many hundreds of advertisements of manufacturing chemists of Germany which are now swamping Switzerland, there is one which arrived a few days ago which is too ludicrous to pass unnoticed. The prospectus states that the product is "untransformed milk, to which bacteria of less virulent origin are added." Just what we are to infer from "less virulent origin" is a mystery, since no bacteria of any origin are otherwise referred to. But marvelous to relate, this product given in subcutaneous injections cures *"pure cerebral epilepsy"* in the clinics of Mayence, Frankfort, Bonn, Vienna and Prague, not forgetting Heidelberg. This surprising product likewise cures cerebrospinal meningitis and lethargic encephalitis. One must suppose that the German neuron differs in structure from that of other races. The product is made in Dresden, but I will refrain from giving its name as you will undoubtedly be advised of its virtues directly from the Fatherland with a brazen attempt made to test the guillibility of the American profession as in other countries.

ILLEGAL MEDICAL PRACTICE

As illegal practice of medicine is not uncommon in the United States and frequently comes before our law courts, the following case tried before the Paris Court of Appeal may not be devoid of interest. Let it be said that the French law of November 30, 1892, defines in clear terms the illegal practice of medicine as follows: This misdemeanor is committed by anyone who, not a possessor of a diploma of doctor of medicine, habitually takes part in, or gives directions for the treatment of medical or surgical cases. Certainly this definition is not ambiguous.

The difficulty in application of this law resides in the fact that numerous quacks have attempted to divert the legal definition by maintaining that there is no illegal practice if the patients have not been subjected to a personal examination. It has also been put forward that if advice is given in a general way through the medium of a book or pamphlet this did not conflict with the law but that it is otherwise when therapeutic measures have been prescribed individually for the patient. But from the viewpoint of the French code, it makes little difference whether the treatment is given by means of a pamphlet, if it is a question of treating a disease from which a person *is* suffering.

The case in question before the Paris Court of Appeal was that of a person who thought he could evade the law by prescribing appropriate treatment for a disease described to him by the patient in writing.

By advertising, he attracted the attention of patients who wrote to him their symptoms, after which they in return received a pamphlet giving the treatment of their case, as well as the cost of treatment. As the accused supposed that as he had never seen the patients and had not given manuscript prescriptions, there was no illegal practice. On this point the Court of Appeal replied that the existence of the misdemeanor in no way supposes a visual examination nor a manuscript prescription, and that in this instance illegal practice is sufficiently established from the fact that, without a diploma of M. D., the accused solicited by extensive advertising his clientèle.

The following are the principal decisions of the Criminal Court where the case was first tried. "Whereas, the widow Bouvard, herborist, solicited a clientèle by means of advertisements in the lay press which said medical advice would be given on some twenty different affections, if patients would apply (by writing), and the use of certain decoctions of herbs would be explained in a pamphlet containing twenty different cures—the work of one Hamon, a priest—offered gratuitously to all those who suffered; that in reply to patients' letters, attracted by this advertising, Bouvard forwarded the pamphlet in question, the cover of which bearing the portrait of the priest Hamon, and containing a preface signed by Hamon; that the profits realized from the sale of medicinal decoctions attained annually the sum of 150,000 francs, and that Hamon, who did not possess the diploma of M.D., had given to Bouvard the right to use his name, and to prepare and sell medicinal products of his own recipes on the condition that he should receive monthly payments in consideration for same; that it was also always by permission of the plaintiff the pamphlet had been published, edited and distributed to patients who asked for it, and in which the author of the work for them prescribed an exactly outlined special treatment for each of the twenty diseases.

"Whereas, from the ensemble of these circum-

stances it results that with the complicity of the priest Hamon, widow Bouvard, who did not appeal from the decision handed down against her, gave advice to patients and habitually took part in the treatment of their ailments; that it is a matter of indifference that neither Bouvard or Hamon did not examine the patients and that the appropriate treatments were prescribed otherwise than by manuscript prescriptions; that in point of fact, art. 16 of the law of November 30, 1892, does not make any provision for visual examination or the writing of a prescription, which are the constituting and necessary elements of the misdemeanor. Hence it follows that the decision of the Criminal Court, that Hamon is guilty of the illegal practice of medicine, is sustained and his appeal rejected.

MEDICOLEGAL

A case of tort presenting some rather unusual legal points was tried in the First Chamber of the Civil Courts at Paris on November 24th last. I will give the essential points of the case as they are highly interesting from the viewpoint of medical jurisprudence.

Returning from Bordeaux to Paris by the morning express a Parisian businessman—Mr. Berthonaud by name—was the victim of an accident in the Montparnasse station (Paris) on June 21, 1923, which resulted in death on July 7th, in the following circumstances. As he was about to alight from his compartment after the train had stopped, the door was suddenly shut by a passing truck pushed by a station employee, crushing the fingers of the left hand. Transported at once to Necker Hospital Mr. Berthonaud received the necessary treatment, including a precautionary antitetanic serum injection, after which he returned to his home. Now, a few days later the injured hand presented the characteristic signs of a peculiar type of infection known as Arthus' phenomenon, which in some instances is a sequel to antitetanic injections. By his physician's advice the patient was urgently admitted to hospital where he died, and his widow brought action against the State Railway Company for damages.

The company held that it was not responsible for accidents occurring to passengers alighting from its cars and that if it was necessary for the victim of an accident to be given an injection of antitetanic serum, the phenomenon of infection resulting from the injection could in no circumstances be considered as a necessary sequel of the accident.

The Court did not sustain this argument and in conformity with the arguments of the widow's lawyer, it maintained the responsibility of the railway company. It decided that in the matter of transportation of passengers, the responsibility of railway companies subsisted as long as passengers were still within the company's station and, on the other hand, since the administration of antitetanic serum was a generally admitted practice in the actual state of medical science and in the circumstances in which it was given to the victim, the morbid phenomena which might be the consequence should, in the given circumstance, be regarded as necessarily belonging to the accident requiring the injection. Therefore the Court ordered the railway company to pay 50,000 francs damages to the widow.

GONORRHEA

As an abortive treatment of gonorrhea made in Germany, we would call attention to intravenous injections of glucose. These are given in conjunction with urethral injections of protargol. It would appear that the process of cure is as follows: The intravenous injections of glucose produce an intense pullulation of the gonococcus, but these neoformed gonococci are extremely sensitive to the urethral protargol injections, destroying them with much greater facility than when the glucose is not exhibited.

With all the innumerable abortive treatments of gonorrhea which have been devised—mostly by German chemical manufacturers—during the past twenty-five years it is curious that still another should be put on the market for the consumption of the medical profession. The treatment under consideration is abortive in name only, because a treatment requiring a fortnight to effect a cure cannot be regarded as especially rapid.

The *modus faciendi* is simple, a fifty per cent. solution of glucose being used in doses of forty centimetres to the injection. Protargol urethral injections are well known. A cure is said to be obtained in from eight to fifteen days, during which time an average of six intravenous glucose injections are given.

As in all other abortive treatments of gonorrhea the great difficulty in obtaining a successful result rests upon the rapidity of the patient's consent to treatment. To inject a concentrated glucose solution intravenously is certainly an act not devoid of possible complications, and although infrequent, they nevertheless occur, since Scholtz and Richter—the initiators of the treatment—refer to them, particularly venous thromboses which, fortunately, have so far been of mild degree.

TYPHOID IN FRANCE

In a French village of two thousand inhabitants, twenty-nine cases of typhoid developed before prophylactic measures could be vigorously applied. One hundred and seventy-three subjects were vaccinated with typhoid-A and B paratyphoid vaccine and 1,236 others with Besredka's bile vaccine taken *per os* three successive days, in the form of compressed tablets of vaccine and one bile pill. Twenty-one new cases of typhoid developed in unvaccinated subjects, while among those vaccinated with the T. A. B. vaccine in four the disease developed on the fifth to the twelfth day following the last injection, while only five cases developed out of the 1,236 persons receiving the bile vaccine, and three of the five developed during the day or on the following day after this prophylactic treatment had been given.

Besredka's bile vaccine offers no contraindications and produces no discomfort, hence it is more readily accepted by the public, especially because it is given by mouth.

RENAL DISEASE

Professor Gougerot, of Paris, has related the following very interesting case of the hematuric renal form of nitritoid crisis following the intravenous use of 914. A physician with fibrous tuberculosis, presenting pulmonary febrile congestive attacks and with syphiliphobia into the bargain, developed muscular gummata of the arm which were proved later to be tuberculous by animal inoculation. At the time

ne lesions were first discovered, the patient de-anded that he receive antisyphilitic treatment and uring an apyretic period of his pulmonary tubercu-sis administered to himself three intravenous in-ections of 914, in doses of 0.15 to 0.30 and 0.45 espectively. As soon as the first injection was iven the patient complained of lumbar pain and ome flushing of the face; with the second, the pain ncreased, while with the third the nitritoid facial henomenon recurred, although mildly, but, on the ontrary, the lumbago was intense, confining the atient to his room, and one hour later he passed loody urine.

One week after this episode, the patient admin-stered to himself another injection of 0.45, but first njecting one milligram of adrenalin, with the result hat the same syndrome took place, namely, a mild acial nitritoid crisis lasting five minutes, intense ilateral lumbar pain lasting for ten hours, then lowly subsiding, the total duration being twenty-our hours. Immediately after the injection, there vas an intense desire to micturate, with hematuria uring the first twelve hours.

In this case there can be no doubt that the nitritoid risis caused renal congestion, resulting in lumbar ain and hematuria. It is likewise probable that here existed a renal predisposition—a congestive enal bacillosis—which attracted the nitritoid crisis o this *locus minoris resistentiæ,* but this supposition ould not be proved, because three animal inocula-ions with the urine remained negative.

DIABETES

In a very interesting clinical lecture delivered by Professor Nobécourt at the Hospital for Sick Chil-lren, Paris, on June 2nd last, on diabetes in chil-lren, he pointed out, among many things, that re-ardless of the numerous researches, the pathogene-is of diabetes mellitus is still badly understood. It s known, however, that the disease arises from a listurbance of the glyco-regulating system, that the issues and viscera of diabetic subjects are incapable f consuming in carbohydrates ingested, with the re-ult that glycosuria and hyperglycemia ensue.

Besides the glyco-regulating disturbances a renal lement intervenes in certain circumstances, but this s not a renal diabetes that one meets with occasion-lly and is the result of renal hyperpermeability to lucose. In the former condition an inverse phenom-non occurs, namely, a rise of the threshold of glyce-nia. It is a phenomenon comparable to that bringing bout azotemia or chloruremia in the nephritides. This is a fact that must be taken into consideration n practice in order to appreciate the influence of diet luring treatment. In point of fact, there are cases n which the glycosuria becomes slight or even dis-ppears and yet the percentage of glucose in the lood remains quite high or even increases. Con-equently, when diabetics are followed, it is essen-ial not only to watch the percentages of the glyco-uria, but also that of the glycemia.

Leaving aside treatment with insulin, which has ts special indications, the treatment of diabetes con-ists of diet poor in carbohydrates or even none whatsoever, and then carefully by experiments to ascertain the amount of carbohydrates tolerated without causing the glycosuria to reappear.

LATIN AMERICA LETTER

(From our own correspondent)

Balboa Heights, C. Z., *May 2, 1924.*

THE ROMANCE OF THE TROPICS

One of the beauties of living in this tropical paradise is its romance—not the romance of gorgeous silver moons and anopheles mosquitoes, or verdant sabannas and red bugs, but the romance which comes from imaginative travelers who come from the hinterland with tales of white Indians, buried treasures and the like. Just now the legend is that of the inhabited pre-Incan city of the Darien. Several years ago, so it is related, a daring flying man actually saw this old stone city nestled in the jungles far in the land of the Cuña Indians. Flying low, he discovered that it was inhabited by white men and women. Right there ends the narrative. Who this aviator was and why he never followed up his find, nobody knows. Perhaps his imagination ran down. At any rate a celebrated author believed the tale and preserved it in one of his books. Recently, he has returned to the Isthmus and outfitted for exploration work. He is reported to have gone into the San Blas region and it is believed that he is in search of the fabled city which has thus far eluded every explorer since the days of Lionel Wafer, who was Dampier's surgeon and lived with the natives of that section in the seventeenth century. While it is improbable that he will discover this mythical city, he may find things of value and interest. There are plenty of evidences of bygone civilization all over Central America and without doubt there are plenty of architectural and monumental remains there which are still hidden. The descendants of those who erected some of them still exist and their ethnology is a subject which demands increasing study. The botany and zoology of this region have never been subjected to intensive research; the field for exploration is by no means exhausted and every expedition brings back additions to our store of knowledge.

THE POISONOUS SNAKES OF PANAMA

Dr. Thomas Barbour, of the Institute for Research in Tropical America, the Museum of Comparative Zoology and the School of Tropical Medicine of Harvard University, has sailed for Cuba after spending several months on the Isthmus of Panama. He has done an enormous work in the completion of the laboratory at Barro Colorado Island, which is already the Mecca for research workers in tropical biology. Dr. David Fairchild, of the United States Department of Agriculture, Professor William H. Wheeler and Dr. George H. Parker are expected to begin work at the laboratory in early June, and other noted scientists will join them soon after. Before sailing Dr. Barbour gave an illustrated popular lecture at the Balboa Community House on The Poisonous Snakes of Panama. To a packed house he explained the mechanism of the poison glands and fangs of snakes in general and exploded the tommygoff myth by saying that "a tommygoff is any snake of which a Jamaican is afraid." According to Dr. Barbour the venomous snakes of Panama are among the most poisonous in the world, including four varieties of true coral snakes, the small palm-

viper, the bushmaster and the *fer-de-lance*. There is only one variety of rattlesnake known to exist on the Isthmus. There is a sea snake which is frequently seen on the Pacific, sometimes several miles out at sea, which is exceedingly poisonous. So far as is known, there is only one variety of poisonous toad in this locality, the *Dendrobates tinctorius*, about two inches long, almost black in color with bright green markings on its back. This furnishes the active ingredient of the arrow poison of the Colombia Indians. They heat it alive over a slow fire when a thick whitish fluid is exuded from the dorsal surface of the toad. Arrowheads rubbed in this excretion are intensely poisonous.

NEW CHIEF HEALTH OFFICER

Colonel H. C. Fisher, Medical Corps, United States Army, who has so successfully discharged the important duties of Chief Health Officer of the Panama Canal for the last four and a half years, will be relieved on June 21, 1924, by Colonel W. P. Chamberlin, Medical Corps, United States Army, who sails from the United States on June 12th for that purpose. Colonel Fisher will assume command of the Army Medical School at Washington.

SANTO TOMÁS HOSPITAL OPENS

The New Santo Tomás Hospital is now operating, sixty-eight patients having been transferred from the old institution. It is expected that the occupancy of the new plant will be completed in August and that the formal inauguration of the institution will take place in September. The buildings of the old plant are located in a congested portion of the city and will be remodelled as modern school buildings of which Panama is greatly in need.

THE GORGAS MEMORIAL ORGAN

As a memorial to Major General W. C. Gorgas, it is planned to install the finest church organ in Central America in the Episcopal Cathedral of St. Luke at Ancon, C. Z. Largely through the efforts of Dr. Gorgas, St. Luke's Church, the predecessor of the present cathedral was erected. It was a small wooden structure and was located on the grounds of Ancon Hospital and Gorgas was for many years its Senior Warden. Already $5,000 have been subscribed for the purchase of the memorial organ.

CANAL ZONE MOTHERS ORGANIZE

On April 11, 1924, the Canal Zone Association of Mothers was formally organized at a meeting called under the aegis of the Health Department of the Panama Canal. It was addressed by Dr. W. C. Cox on The Relation of a Mothers' Club to the Community. Colonel H. C. Fisher, Medical Corps, United States Army, the Chief Health Officer, spoke on The Community and the Spread of Infectious Disease, and Surgeon C. P. Knight, United States Public Health Service, delivered an address on Mothers' Associations. Chapters of the association have been formed on both sides of the Isthmus and are already doing good work. The publicity campaign which Colonel Fisher has so actively championed is continuing and the "How To Keep Well" column in the English and Spanish papers of Panama is being read both in the homes and the public schools; thus the community health consciousness for positive public health is being awakened and sustained.

DEATH OF DR. VAZ

Dr. Charles Alfred Vaz, for many years *Medico oficial* of Bocas del Toro and one of the best known physicians of that Province, died suddenly on April 8, 1924.

PRIZES FOR ARGENTINA PHYSICIANS

The jury designated in the Concurso Nacional de Ciencias of Buenos Aires awarded the first prize of 30,000 pesos to Dr. Bernardo J. Houssay for his work entitled The Physiological Action of the Hypophysis, the second prize of 20,000 pesos was divided between Dr. Fernando Perez and Dr. Joaquin Llambias respectively, for their works, The Study of Comparative Anatomy in Relation to Otology, and Lessons from Pathological Anatomy and Physiology. Dr. Houssay is the director of the Physiological Institute of Buenos Aires and his investigations have provoked much attention both at home and abroad.

DELEGATES TO THE LEAGUE OF NATIONS

The President of Paraguay named as medical delegates to the meeting held in Berne, Switzerland, of the second, third and sixth sections of the sanitary section of the League of Nations, Dr. Bemigno Escobar, director of the Asistencia Pública, Dr. Alberto Schenoni, dean of the Faculty of Medicine, Dr. Carlos Leon, Military Surgeon, and Dr. Andres Gubetich, physician of the National Hospital.

COSTA RICAN GRADUATES

Fourteen diplomas were issued as the result of the December examinations given by the Board of Medical Examiners at the School of Obstetrics and Nursing at San Jose, Costa Rica.

NEW MEDICAL FACULTY

On January 5, 1924, the new board of directors of the Medical Faculty of Costa Rica was installed. Those composing this body are, president, Dr. Solón Nuñez; secretary, Dr. Ricardo Moreno Cañas; treasurer, Dr. Benjamín Hermández; attorney, Dr. Constantino Herdocia and Dr. Carlos Pupo, Dr. Roberto Chacón and Dr. José Maria Barionuevo. The medical faculty has taken charge of the Maternity Hospital in San Jose. It plans to hold a series of clinical conferences.

NOTES FROM CHILE

In 1923 the Woman's Anti-Tuberculosis Association of Santiago expended 70,369 pesos and had a balance on hand of 19,417 pesos at the close of the year. This organization supports two antituberculosis dispensaries in the capital, where 539 patients were attended during the month of December, 1923.

The Experimental Hygiene Section of the Army, which has an excellent clinic and carries on valuable work in Santiago, has decided to send representatives through the southern portion of the Republic to give information and treatment in regard to the social diseases. The medical officers composing the commission will not confine their work to garrisons and garrison towns, but will endeavor to inaugurate clinics wherever they may be needed. Lectures, motion pictures, posters and pamphlets will be used in propaganda against venereal diseases.

The graduates of fifteen of the sixteen normal schools of Chile assembled in the Capital, Santiago, to receive their diplomas and were addressed on that

occasion by Dr. Pedro Lautaro Ferrer on The Teachers' Opportunities in Health Education, and by Dr. Ernestina Pérez on Alcoholism and Tuberculosis, the latter speech being illustrated by moving pictures.

The executive board of the Patronato Nacional de Infancia announces that a payment of 5,000 pesos of the 8,000 peso legacy bequeathed the society by Sra. Elvira Caldera de Eastman have been received, as well as the 100,000 pesos left by Sr. Florencio Luna, also that Sra. Bazo v. de Cruz had willed the Patronato 25,000 pesos. These funds have been placed at the disposal of that organization to continue its child welfare centres and similar activities in Santiago. Since the announcement of these gifts another of 50,000 pesos has been received.

A school for male nurses has been opened in connection with the San Juan de Dios Hospital in Santiago with fifteen students in attendance. The course of instruction, which is both theoretical and practical, covers two years. Instruction in the case of patients in their own homes is also given and a good course in the rudiments of public health nursing. It is believed that this will help the cause of preventive medicine in Chile very considerably.

An anonymous donor has given the sum of 500,000 pesos for a clinic of diseases of the eye, which will be built in connection with the San Vicente Hospital in Santiago. Besides a clinic for outpatients and a classroom, laboratory, and library, there will be twenty-five beds. Dr. Carlos Charlin Correa, professor of ophthalmology, will be the director.

Letters to the Editor.

ALCOHOLIC POISONING

GREAT NECK, N. Y., *August 29, 1924.*

To the Editor:

In the MEDICAL JOURNAL AND RECORD of August 20, 1924, there is an editorial article entitled "Better Late Than Never"—claiming a cure for alcoholic intoxication, which does not seem to me to be justified. To begin with, alcoholic intoxication is nothing but a poisoning by alcohol and any treatment overcoming this condition should be classed as an antidote.

An antidote for alcoholic poisoning has been known to a few physicians since before 1908, when I first became acquainted with it. I was then house physician on the First Medical Division at Bellevue Hospital. Dr. E. LeRoy Dow was assistant visiting physician of my division and told me one day to use six to eight drops (not minims) of pure carbolic acid well diluted in any case of severe alcoholic poisoning. Some time later a drunken man was admitted on my service about 2 p. m. He was too severe a case for the alcoholic ward. He was almost pulseless, his heart's action was weak, he breathed with difficulty and he was unconscious. I gave him caffeine and strychnine by hypodermic injection. A few minutes later, when his pulse and respiration were better, I washed out his stomach with warm water, and at the end of this procedure, poured an ounce of epsom salts dissolved in about one and a half ounces of water, down the stomach tube and then withdrew it.

About an hour after his admission, I dissolved four drops of pure carbolic acid in four ounces of cold water and gave it to him to drink. About 4 p. m. I gave him another two drops in two ounces of water. At 6 p. m. he was as sober as any man can be. He had no headache or nausea, and he asked permission to leave the hospital, which I granted.

This case is on record at the hospital and as far as I can remember, he came under my care about October, 1908. Carbolic acid acted as a true antidote and I cannot imagine any antidote whose action would be quicker and more efficient.

Since those days I have had several cases of alcoholism and a few drops of carbolic acid sobered them in a couple of hours. When I look back I can think of one mistake that I made, namely, washing out the stomach with water—I should have washed it out with six or eight drops of carbolic acid dissolved in a quart of water. In that case the man in question would probably have been sober by 5 p. m. instead of an hour later.

Men who have taken drinks—especially whiskey and cocktails—and who later on have to attend some society function and do not wish the odor of alcohol on their breath, need only take two or three drops of carbolic acid in two or three ounces of water, and all evidence of alcohol will disappear in about ten minutes. Of course the delightful feeling of *bien-être* will disappear too.

I am amazed at the fact that medical textbooks and books on poisons and their treatment, do not mention carbolic acid as an antidote for alcoholism. As carbolic acid neutralizes alcohol, it naturally follows that alcohol will neutralize carbolic acid. I shall illustrate this by a case. When I was on the Children's Service at Bellevue Hospital from October, 1907, to the end of that year, a child was brought in to whom its mother had given a teaspoonful of carbolic acid by mistake. The child was in coma, the pulse could not be felt, nor could the heart beat be heard, as there were so many sibilant and sonorous and bubbling râles in the lungs. In a case like this one has to think and act quickly, and it flashed across my memory that I had cauterized wounds with carbolic acid which I neutralized by alcohol. So naturally I made a weak solution of alcohol and washed out the child's stomach with it, and at the same time the nurse got ready a hypodermic syringe with adrenalin and gave the child five minims.

A quarter of an hour later I gave another injection of four minims of adrenalin. The adrenalin was given to stimulate the lungs and overcome the congestion there. In less than an hour the child came to and was crying in the mother's arms. This case is also on record at the hospital.

Here again is another antidote, viz., one for carbolic acid poisoning. Yet cases of this kind were frequently admitted in the alcoholic ward but never in my time treated by washing out the stomach with alcohol. Nor will you find any mention of this treatment in any textbooks or books on poisoning. It is strange, is it not?

I know of other cures that have been ignored by the medical profession, but I shall not mention them here, as I do not wish to take up your time.

F. TWEDDELL.

Book Reviews

GASTRIC AND DUODENAL ULCER

Gastric and Duodenal Ulcer. Two Lectures. A Record of Ten Years' Experience. By Sir Berkeley Moynihan. Bristol: John Wright and Sons, Ltd.; New York: William Wood and Company, 1923. Pp. 48.

Moynihan's definition of an ulcer of the stomach or duodenum is "a visible and palpable lesion which has existed for months or years. In it are seen clearly the evidences not only of destruction but of stubborn defence; there is a crater of varying size; in depth the ulcer involves at least the muscular coat, and may extend completely through all the coats, an acute perforation being prevented only by the firm adhesion of the ulcer to a neighboring structure which then forms its base." Gastric ulcer, according to the author, is a rare condition. In case it cannot be removed by operation Moynihan performs a gastroenterostomy combined with jejunostomy. The patient is fed through a tube which passes directly into the jejunum, and no smallest quantity of food, solid or liquid, is given by the mouth. The healing of the ulcer, which is watched by screen examination with the x rays, is always very slow and requires six months to three and three quarter years.

Moynihan deprecates medical treatment and sees the only salvation for the patient in surgery. Of duodenal or jejunal alimentation which nowadays can be done by the duodenal tube without recourse to jejunostomy, not a word is said.

In duodenal ulcer three operations are applicable: 1, excision of the ulcer; 2, anastomosis of the stomach to the duodenum, with or without excision of the ulcer; 3, anastomosis between the stomach and jejunum. In postoperative jejunal ulcers of greater severity (profuse hemorrhage, etc.) Moynihan again advocates a jejunostomy for feeding the patient until he is able to stand the risks of a radical operation. There again the duodenal tube would make the temporary operation of jejunostomy superfluous.

The lectures contain many useful points.

GASTRIC AFFECTIONS OF RENAL ORIGIN

Gastropatias de Origen Renal. Estudio Clinico y Patogenico. By Juan Raoul Goyena. "El Ateneo." Buenos Aires; La Semana Medica, 1924. Pp. 191.

This excellent book of Professor Goyena on gastric affections of renal origin is of great importance. It is the first monograph on this subject compiled in book form. Goyena says: "The action of the kidney can influence the stomach in four different ways; 1, purely through the nerves; 2, through the blood; 3, through both blood and nerves, and 4, mechanically. The gastric manifestations evoked by floating kidney (or nephroptosis) are thus described by Goyena: "The dyspepsia which accompanies a movable kidney can be of either the hyposthenic or the hypersthenic type. In the first instance there is present atony of the stomach, flatulence, habitual constipation, and occasionally abdominal pains and vomiting. Nausea is likewise frequently encountered. The patients assert that their troubles set in with the commencement of the digestive period and complain of fullness and distress in the gastric region. Sometimes these symptoms appear before the meal is finished, and last for some time. A sleepy sensation and general fatigue are also encountered.

The epigastrium is usually painful to pressure. Further examination of the abdomen occasionally shows tenderness over the kidney region, which is of great assistance in the diagnosis. The gastric secretion is usually not much changed in this variety.

In the hypersthenic form pyloric spasm is frequently met with. Here there appear pains late after meals and vomiting is often encountered.

THE DUODENAL TUBE

Le Tubage Duodénal. Ses Applications Cliniques. Dans la Collection Médecine et Chirurgie Pratiques. M. Chiray et J. Lebon. Avec 24 Figures et 2 Planches en Couleurs. Paris: Masson et Cie, Editeurs, 1924. Pp. 208.

Die Duodenal-Sonde und Ihre Anwendungsmöglichkeit. Von Max Einhorn. Deutsche Ubersetzung von Lillie Oberwarth. Leipzig: Verlag v. Georg Thieme, 1924.

Chiray and Lebon give in this monograph an excellent exposition of the important work done in America, Germany, and especially in France, with Einhorn's duodenal tube. In case of chronic jaundice, according to Chiray and Lebon, the following rules can be laid down by the results of the duodenal intubation regarding differential diagnosis. A. When the duodenal contents show absence of bile and pancreatic juice at the same time, and no blood, the probability is that we have to deal with a neoplasm of the head of the pancreas. B. When absence of bile and pancreatic juice is associated with blood in the duodenal contents, we usually have to deal with cancer of the papilla of Vater. C. When there is no bile but pancreatic juice present in the duodenal contents, we have to deal with compression of the choledochus, either by a calculus, a neoplasm, or constriction by adhesive bands.

* * *

A few weeks ago a German edition of Einhorn's recent book *The Duodenal Tube and Its Possibilities*, appeared on the market. Whoever has taken the time to study the various chapters of this book must have been impressed with the originality and the ingenuity of the author in inventing and constructing useful instruments, which have made accessible to diagnostic research and conservative nonoperative treatment "from above," the entire gastrointestinal tract down to the pelvic colon, inclusive of the secretions of the liver and pancreas as they are physiologically discharged into the duodenum.

Inasmuch as a thorough revision of the book appeared in a number of medical journals three years ago, a more detailed discussion of the many interesting procedures described therein and elucidated by an abundance of instructive illustrations will not here be entered into again. It is best to study them "at the source," although curious to state, the first edition of the book, four years ago, which was soon sold, has so far not been reprinted by the publishers nor have important additions on the part of the author been made accessible to the medical profession in a second enlarged edition. It certainly is

grettable that the price was not made higher from ıe start. Perhaps it would then have been con- dered worth while by the publishers to bring out ırther editions of a work so pregnant with new ıd useful ideas. Surely arrangements should be ıade at once that the English edition of this book ɔes not remain permanently "out of print," that a ew edition is placed at the disposal of those col- agues who wish to own a copy, instead of forcing ıem to hunt it up in shops that deal with "antiquated ɔoks."

The new German edition is a replica of the orig- ıal English one, with the exception that chapters on ver, gallbladder, and bile duct affections (pp. 39- 5), on cardiospasm and pylorospasm as discovered y the delineator (pp. 104-115), and on the treat- ıent of ulcerative colitis by colon lavage from above pp. 127-142) have been added.

It is a subject for congratulations to the German ɔeaking colleagues abroad, that the contents of this ractical and compact book have now been made ccessible to them. It will no doubt bring untold essings to suffering humanity, also on the other de of the Atlantic, and will in many emergencies ıtimated in the book—for example, the conservative eatment of the duodenal fistula, so difficult and nsafe to treat in reduced patients by operative pro- ɛdures—contribute to save life.

It is to be expected that translations into all the ɛher modern languages will soon follow. Wherever ıtelligent medical men and women carry on their gitimate practice, Einhorn's pathfinding work in ıe diagnosis and conservative treatment of diseases f the gastrointestinal tract and attached important lands should be thoroughly studied and employed.

THE DYSPEPTIC STATE

'Etat Dyspeptique. Affections du Tube Digestif. Dans La Collection Médecine et Chirurgie Pratiques. Léon Meunier. Avec 37 Figures et Schémas. Paris: Masson et Cie, Editeurs, 1924. Pp. 128.

In this little book of 128 pages Meunier presents is philosophy of the dyspeptic state. He defines ıis condition as a nonspecific painful syndrome hich includes all gastroduodenohepatic pathology. Ie believes that at the bottom of this painful state ıere is always impaired gastric motility. This con- ition in turn produces a two fold defense on the art of the stomach, namely, by aerophagia, and by rolonged secretion. The symptomatology is then urther developed and an outline for the diagnosis f the chief etiological factors is presented. These actors are: 1, Functional (neurosis); 2, gastritis; , gastric ulcers; 4, biliary lithiasis; 5, duodenal lcer. In these sections of the book the author de- ɛribes his test for digested blood in the gastric con- ɛnts, his method of aspirating the stomach with the atient leaning forward over a table, and his method f testing the duodenal contents for alkalinity.

The therapy of the dyspeptic state is then pre- ented, the chief parts of interest being the use of ıedicinal saline solutions of such cryoscopic con- entration as to favor gastric evacuation, strength- ning of the abdominal wall by special physical exer- ises, use of hot infusions to aid digestion, and pecial dietotherapy.

The book makes interesting reading.

DISEASES OF THE DUODENUM

Etudes médico-radio-chirurgicales sur le duodénum. Par Pierre Duval, Jean-Charles Roux, Henri Béclère. Paris: Masson et Cie, 1924. Pp. 269.

Duval, Roux, and Béclère give in this important work an excellent exposition of the diseases of the duodenum. According to the authors, a periduodenitis due to cholecystitis, as evidenced by adhesions between the gallbladder and duodenum, is a very frequent occurrence. Even after a cholecystectomy it is apt to persist and necessitates occasionally a second operation. The writers are convinced that adhesions frequently form after cholecystectomies, but that they ordinarily give no rise to clinical symptoms, unless when they begin to interfere with the motor power of the duodenum or when they lead to a stenosis of this organ. In these instances a gastroenterostomy becomes necessary. Under the term "primary stenosing periduodenitis" the authors describe adhesions over the duodenum *not* due to gallbladder lesions nor to any ulcerative process within the duodenum. Here also a gastroenterostomy becomes necessary when the obstructing symptoms become manifest. This excellent book on the duodenum is herewith highly recommended to the medical profession.

OBESITY AND CONSTIPATION

The Culture of the Abdomen. The Cure of Obesity and Constipation. By F. A. Hornibrook, F.R.C.S., D.P.H. (Ireland). Preface by Sir William Arbuthnot Lane. New York: William Wood and Company, 1924.

This is a book of sixty-eight pages, the last eighteen of which describe the *daily eight* which are the exercises used by Mr. Hornibrook. This system is recommended by Sir Arbuthnot Lane, consulting surgeon to Guy's Hospital, the writer of the preface. Dr. Lane makes the statement that Mr. Hornibrook has treated a large number of people most successfully. The purposes of these exercises is the treatment of constipation and reduction of the waistline. They are suitable for attaining these objects and therefore it is easy to understand why Mr. Hornibrook has been successful as Dr. Lane states.

TEXTBOOK ON X RAY DIAGNOSIS

Lehrbuch und Atlas der Röntgendiagnostik in der Inneren Medizin und Ihren Grenzgebieten. Herausgegeben von Franz M. Groedel. Weiterte, vollkommen umgearbeitete und wesentlich erweiterte Auflage. Mit 712 Abbildungen auf 179 Glansdruk-Tafeln und mit 720 Text-abbildungen. 1 und 2 Halbband. Lehmann's Medizinische Atlanten, Band 7. München: J. F. Lehmann's Verlag, 1924. Pp. 1109.

This fourth edition in German has been enlarged by the addition of 42 plates and 180 illustrations in the text, also by sections on the constitution of men in röntgen pictures; on pathological lung pictures, on röntgenological differential diagnosis of abdominal diseases by means of pneumoperitoneum; on röntgen diagnosis in diseases of childhood. The list of contributors has been given here because they are among the great men not only in röntgenology but in the various specialities in medicine.

To one unfamiliar with the previous editions this must be described as a monumental book of the greatest interest and full of absolutely essential information for those making or interpreting x ray pictures or using the fluoroscope. The chapter on

apparatus and technic would be a sufficient guide for the beginner in x ray work and proceed to such advanced details as the orthodiagraphic and teleröntgenographic measurement of the heart. In each of the clinical sections the normal x ray appearance is fully demonstrated, as well as the greatest variety of pathological conditions.

The text and its drawings make the work an invaluable textbook for one seeking to qualify himself as an expert in röntgen diagnosis and also as a book for reference by the röntgenologist and the physician.

The normal pancreas never shows in ordinary radiographs. But Hassel has demonstrated it by having the stomach and intestines thoroughly emptied, extreme pneumoperitoneum (inflation of the peritoneal cavity with air or oxygen or carbon dioxide), the x ray tube underneath, patient prone, if very heavy take off some of the pressure by cushions under sternum and pubis, plate over the back, very soft tube and exposure as short as possible. The pressure from the weight of the body causes the gas to escape rapidly through the puncture by which it was introduced and it may also infiltrate the tissues, emphysema extending to the neck sometimes. The diagnosis of the pancreas abnormality, such as tumor or cyst, made by means of an ordinary radiograph directly or from its effect upon the outline of the stomach, is one of the subjects discussed.

Special chapters give the fullest and most accurate information regarding x ray diagnosis in diseases of the brain, spinal cord, and peripheral nerves, of the eye, of the ear, of the jaw and teeth, of the upper respiratory tract, of the thorax including the diaphragm, to mention only one quarter of the topics. A complete bibliography accompanies each chapter.

The 712 radiographs are reproduced by an autotype process which gives an almost perfect similarity to a photographic print, gloss and all. And although some of them are quite small the screen employed is so fine that a magnifying glass may be used without losing details of the picture.

ENDOCRINOLOGY

An Outline of Endocrinology. By W. M. Crofton, B.A., M.D. New York: William Wood and Company, 1924.

A most convenient manual giving a concise and aptly illustrated résumé of the essentials of endocrinology. This book does not enter into competition with the more ponderous tomes dealing with the many theoretical considerations of the internal secretions, but is admirably suited for the purpose for which it was intended.

HEREDITY

Race Hygiene and Heredity. By Hermann W. Siemans, M.D. Translated and Edited by Lewellys F. Barker, M.D. Illustrated. New York and London: D. Appleton and Company, 1924. Pp. 178.

A considerable debt is due to Barker for his admirable translation of this monograph on heredity. The text is brief, and brings the salient points into sharp outline. The reading of this small book is both interesting and stimulating. In spite of the many limitations imposed by our numerous pseudo and actual cultural layers, we get a slight glimpse into a future when many of the findings of men of science like Galton, Weismann, and others will be made use of.

PHYSICAL DIAGNOSIS

Perkussion, Auscultation und Palpation der Brust und Bauchorgane. Ein praktischer Grundriss. Von Dr. L. Dünner und Dr. R. Neumann. Mit einem Vorwort von Geh. Med.-Rat Prof. Dr. George Klemperer. Mit 5 Abbildungen im Text. Wein und Berlin: Urban and Schwarzenberg, 1924. Pp. 154.

This is a practical manual of physical diagnosis designed for students. There is accordingly no discussion of the physical basis of physical signs but rather a correlation of the facts of physical diagnosis with their clinical and anatomical basis. It represents the method of teaching of Professor Klemperer in the IV medical clinic in the University of Berlin. Chapters are devoted to the physical examination of the healthy lungs, heart, and abdominal viscera, as well as to these organs in the diseased state. Two chapters, giving in outline form abnormal physical signs that may be elicited in the lungs and heart, should prove of real value to the student.

BIOLOGY

Moderne Biologie. Heft 6. Die Heterogenetischen Hammelblutantikörner und Ihre Antigen. Dr. Hans Schmidt. Leipzig: Curt Kabitzsch, 1924.

The refinement of specialization could scarcely go further than the production of a monograph on the heterogeneous antibodies produced in sheep's blood by the injection of various antigens. Those laboratory workers whose business in life necessitates their being informed on such subjects will find this a useful compendium of what we know, with an up to date bibliography.

THE CARE OF CHILDREN

What Every Mother Should Know About Her Infants and Young Children. By Charles Gilmore Kerley, M.D. Second Edition, Revised. New York: Paul B. Hoeber, 1924. Pp. 103.

This little book, although published in pamphlet form, is attractively gotten up as to cover, paper, and typographical form. Doctor Kerley writes in his preface that it has been prepared as a ready reference for busy mothers regarding the care of their children, and that its purpose is to place in the hands of the mother of moderate means, concise, readily understood and practical instruction. The subject matter is discussed under thirteen headings, including hygiene, maternal nursing, artificial feeding, food formulæ for well infants, feeding from first to sixth year, diet after sixth year, dentition, ailments, first aid to the baby, general instructions, general considerations, don'ts, and formulæ.

CHILD MEMORIES

The Birth of Psyche. By L. Charles-Baudouin. Translated by Fred Rothwell. New York: E. P. Dutton & Co., 1924.

This small delicately tinted volume is well named, for from the secret depths of the child mind rises evanescent, exquisite, the being that is to be. A collection of child memories, not so significant in themselves, yet rich in association material for the author. Most interesting, perhaps, is the fact that these supposedly earliest recollections may well be threshold memories, covering still earlier recall from an unbelievably tender age. The steam roller dream and obsession would probably lead very far back.

One wonders whether it is possible to recapture mosphere. The sketches would seem to have done perfectly. But are the remembered thoughts what child really thinks? Did he have perceptions that ould be remembered for those aching, uninterpreted nages? Can one ever again really see with the lim- d eye of a child? Psyche, being born, falls in love id becomes a woman. Thus each of us having be- me men and women, looks back to draw a trem- ling breath at those early memories, those stirrings f ourselves. Is there really anything left!

ZOOESTHETICS

he Man in the Zoo. By David Garnett. New York: Al- fred A. Knopf, 1924. Pp. 119.

Not having read the famous *Lady Into Fox* by iis author, we have probably missed his fantasy : full bloom. *The Man in the Zoo* is an elabora- on of an interesting idea, but it does not waken :her ideas in the reader's mind. It is well worked ut—the singled thought—Why not exhibit man mong the other mammals? A little romance weaves bout the idea and behold it is a book. The sort f delightfully chintz bound volume to place on ie night table for the week end guest at a country ouse. Not likely to disturb his slumber either by ight or day.

ATAVISM

rdeal. By Dale Collins. New York: Alfred A. Knopf, 1924. Pp. 298.

We have been following the hypothetical, daily fe of primitive man of late, and Collins's book gives ascinating support to placid scientific theory. No udent of anthropology could have made out a bet- r case for social evolution, for Freudianism, for ie unchanging truth of the unconscious mind.

The book pictures five people on a little yacht in iid-Pacific; five people of the polished acme of ociety. A great gulf yawns between them and the rew, bridged by Ted, the steward, alien to either ass. Insufficiently equipped, undermanned, the acht bears its burden further and further from ivilization towards the "thrill" the wealthy own- rs are seeking.

The thrill comes not as they expected. In fact ie absence of thrill is their undoing. Becalmed, iaddened by heat, silence, their own society, the ve slip bit by bit through every culture level to es- ential beginnings. Paul Thorpe, the owner, as a aveman would have been as long suffering with is wife, save for flares of tired jealousy, as he is n the yacht. Vazey Howard, nice young man, ould even in paleolithic days been upstanding but everent towards the "old man." Woman's emanci- ation in the last centuries has told on Viola Thorpe o a certain extent. She clings rather to the sensu- us medieval level, but there are slips back to more rimitive strata. Essentially, however, her prosti- ute complex is laid bare, the undercurrent in so iany neurotic lives. While the torture of the weeks rings Dorothy Daley, the chilly English girl, to uller, more natural expression than she had ever nown before. Then there is Lady Daley, Dorothy's eaf aunt. The world does not change for her since er whole world is within her. She only of them ll faces things, sees with apparent uncanny shrewd- ess each step in advance. But the things are ob- vious, and only obscured by the unreality of the experience. They are all of half a mind that it is a bad dream.

Through the terror grins the bestial face of Ted, the fox, the viper. From fawning stewardship to brutal master, he progresses upward, wreaking his long pent resentment on the society that has counted him inferior. The storms and ominous calm of the tropic seas, waver and crash outside and inside the ship. The elements have in Mr. Collins a sympathetic, vigorous historian, whose perspective on mere man in the gigantic turmoil of the cosmos is both admirable and refreshing.

The reader must follow for himself the steps leading up to the sacrifice, the final winning free from the talons of Ted. The book is not one to love and reread like a familiar friend. It is too arresting. But it will never stale and will meet each mood with its primal tang and bite as pronounced as at first reading.

SOMBRE PATTERNS

The Dark Night. By May Sinclair. New York: The Macmillan Company, 1924. Pp. 126.

Miss Sinclair seems to be experiencing the unrest of many writers over the fatuousness of words. In life what do words matter. They mar living. They prevent thought. The most vivid experiences come in muscle flashes, reflexes, that have to be painfully translated into words—words that in turn mean nothing to the reader except by retranslation into the original impulses.

For years Miss Sinclair has been getting down to bed rock. Her stories have been pared down and pared down to simple shock of forces, feeling against feeling, instinct against instinct. She has been working herself out, along with the other curious animals inhabiting this planet. There are not many avenues of human behavior that she has not explored.

It all comes down to one thing, an elusive pattern, grey, grim. Love is *reality*—not happiness. And the reality of a primeval patter has colored all Miss Sinclair's romances.

There is always someone, something to wreck the perfect blending of souls. It may be the animal in man, or it may be some psychic conditioning that dreads great happiness for fear of retribution. There is usually in Miss Sinclair's books an idealistic love, the kind dreamed of by adolescents. It endures and suffers empty handed while passion is temporarily regnant. In the end the idealistic love triumphs, either actually, or by selfimmolation.

In this latest story Miss Sinclair has given only a story sketch, like the first draft of highly impressionistic verse. She had here the makings of a powerful novel—was it lack of patience that caused it to be left? We do not think so. Rather, perhaps, the souring on her tongue of words, words.

As a poetic rendering the book is unremarkable. It bears an uneasy resemblance to the *Song of Songs.* It echoes the *Elder Edda.* But that does not make it literature. On the whole it is humdrun in style, though not in matter.

Elizabeth, heroine, and a poet hero are to marry. The poet cannot bear to be caged, he flees to Italy. The long suffering Elizabeth finds God in her lover's

place during his absence. But they do marry in the end, and some five years later, Monica, a perverse ward to whose happiness Elizabeth is dedicated, comes to live with them. The poet loves the ward. Elizabeth sets him free, and finally when poverty comes to the couple and their child, gathers them in again. (All except Monica who has found a better provider). Altogether a childish performance, pitiful because so often repeated in real life. There are people who wallow in distress. Elizabeth is one of them. They surround themselves with others who unconsciously prey upon their weakness. On the whole the book would be a fair enough clinical picture of masochism, were it not for its sentimentality. That ruins it. It loses all value as propaganda, even as art. No wonder Miss Sinclair couldn't make a novel out of it. To spread a subjective lather over the requisite pages for a big work, one has to believe in it. We are thankful Miss Sinclair does not.

THE TWENTIETH CENTURY IN THE MAKING

These Eventful Years. The Twentieth Century in the Making. As Told By Many Of Its Makers. Illustrated. Two Volumes. New York: Encyclopedia Brittanica, Inc., 1924.

Surveys are so frequently handled by middlemen, literary and unliterary beings picked for their seeming aptness for the special job on hand. The result is homogeneous, more inclined to be flat than thrilling, or is thrilling lacking the ring of accuracy. The chroniclers of the twentieth century in the making, however, are the actual figures in its shaping. They are not writing men necessarily. They are something more. They have lived what they describe. They have been so close to the turmoil of battle, to the whirlpool of discovery, to high peaks of achievement, that they bring to their descriptions the *feel* of themselves shining through their careful details. One may think that the best judgment comes from the disinterested spectator. But not in this case. Fifty years from now, a hundred years, these directors of destiny will still start from the page as personalities. What they achieved will be something greater than bare fact because of what these men and women are.

The war, its causes, its course, its outcome and aftermath, occupy most of the first volume. The resultant condition in Europe, the hopes the nations have for themselves, and the triumph of the new century over the old, especially evident in Chinese history as written by former Ambassador Wellington Koo, round out in admirable fashion the overshadowing events of the troubled period which we hope is drawing to a close.

What of the rest of the Twentieth Century? The second volume projects it—nationally, scientifically, in the arts, in every conceivable department of human interest. There is food for every thinker in these volumes, not just opinions that he will value no more highly than his own, but the authoritative voice of the greatest thinkers on each subject. For the time being all animosities are forgotten. We get the honest beliefs of men and women on their own life interests. What could be more magnificent a human document!

The list of contributors includes names so well known that one cannot cite some and leave the others unmentioned. Suffice it to say that these two volumes give the gist and equivalent of the careful thought of nearly eighty of the greatest men of action, thinkers, writers, physicians, explorers, scientists, that this century knows. *These Eventful Years* is *the* indispensable handbook. It is a library in itself, a treasure house of everything that has been done and well done during these busy times that dash over us almost without our realizing them.

Medicoliterary Notes.

The *Century* for August contains a number of worth while articles, among them *The Betrayal of Our War Veterans,* by Charles Merz; *The Sense of Immortality,* by Philip Cabot; *The Lip-Lazy American,* by Edward W. Bok; *America's City Civilization,* by Shaw Desmond; *The Discovery of Truth in Universities,* by Walter Dill Scott, and *Irony in Velvet,* a discussion of James Branch Cabell's stories by Carl Van Doren.

* * *

The book review section of *Mental Hygiene* for July contains among others interesting reviews of the following works: *The Recreating of the Individual; A Study of Psychological Types and Their Relation to Psychoanalysis,* by Beatrice M. Hinkle, M.D., reviewed by Dr. C. Macfie Campbell of the Boston Psychopathic Hospital; *Psychoanalysis and the Drama,* by Smith Ely Jelliffe, M.D., reviewed by Karl A. Menninger; and *The Ku Klux Klan,* by John Moffatt Mecklin, reviewed by Nancy Boyd Wiley. Articles of special interest in the same number are *Constructive Possibilities of a Mental Hygiene of Childhood,* by Bernard Glueck, M.D.; *A Study of Certain Autoerotic Practices Based on the Replies of 2,255 Women to Questionnaires Prepared by the Bureau of Social Hygiene with the Advice of a Cooperative Committee; Part I;* and *A Plea for Greater Frankness in Dealing with Those Who Are Mentally Sick,* by Ransom H. Sartwell, M.D.

* * *

On Being Shocked is the title of an entertaining essay by Stephen Gwynn, quoted in a recent issue of the *Living Age* from the London *Spectator.* After an amusing discussion of the present day prevalence of the will to shock, and the unquestioned value of being shocked, the writer brings to a more serious concluson by stating that "it is well not to forget that a society or a person no longer able to be shocked has lost in this fastidiousness a quality which is akin to honor—which is indeed honor in another aspect; not noisy, not querulous, nor quarrelsome—for those in whom disgust strikes deepest at a gross word or ugly action keep least cry about their sensibility—but an instinct guiding conduct and judgment to avoidance, just as surely as honor prompts to do."

* * *

In a recent number of the Berlin *Deutsche Allgemeine Zeitung,* Prof. Friedrich von Lucanus writes on the sense of locality and power of orientation in men and animals. He believes that in both the basis of the instinct is an innate sense of the main points of the compass, and advocates that the theory be made the subject of experiment by scientists.

* * *

Osteopathy's First Half Century is the title of a pamphlet by George W. Riley, Ph.B., D.O. A résumé of the history of this branch of medicine is given from the time of its establishment by Dr. Andrew Taylor Still to the present day.

* * *

Some interesting statistics on divorce in the United States have recently been published. According to the Census of 1922, there was one divorce to every twelve marriages in this country; today, there is one to every seven marriages. The divorce ratio is steadily progressing westward. Among American cities, San Francisco probably holds the record for the largest number. For the year ending June 30, 1923, one of every two marriages in that city ended in a divorce. Except for the District of Columbia, which had only one

divorce for every 35.8 marriages, New York State shows the fewest divorces—one for every 22.6 marriages, Georgia has the next fewest, one for every 19.4 marriages. Pennsylvania has one for every 10.2 marriages. Montana has the highest—one divorce for every 4.3 marriages, with the exception of Nevada, the mecca of divorcés, which is in a class by itself and where the number of divorces granted exceeded the number of marriage licences.

* * *

In 1309 the first clock known to the world was placed in the tower of San Eustorgio in Milan. In 1344 a clock was installed in the palaces of the Nobles at Padua. This was a wonder of mechanism indeed, for, besides indicating the hours, it showed the course of the sun, the revolutions of the planets, the various phases of the moon, the months and the fêtes of the year. In 1420 an alarm clock made its appearance. The chroniclers have placed on record that this clock sounded a bell at a stated hour, and at the same time a little wax candle was lighted automatically. How this was done we are not told, but it must not be overlooked that until about a hundred years ago we had no means of obtaining light other than the tinder box.—*Jeweler's Record.*

* * *

According to Dr. James J. Walsh, it was Pope Innocent III who established the prototype of the modern city hospital, with its purpose of caring for the acutely ill, who may have none to care for them properly, and for the injured. This pope summoned Guido from the medical school at Montpellier to Rome and founded for him the Hospital of the Holy Spirit in the Bargo not far from St. Peter's, where it still stands. This was the mother and model hospital for the world at that time, and visitors came from many parts of the world to admire and to return home to found similar institutions.

* * *

A recent publication of Knopf is *Recreating Human Nature; an Exposition of the Making of Psychology,* by Charles W. Hayward.

* * *

The city of London maintains a museum for the instruction of young constables in the ways and methods of the criminal classes. It is called the Black Museum and contains many queer and uncanny exhibits.

* * *

A new novel by D. H. Lawrence has been announced by Seltzer who will publish it. The title is *The Boy in the Bush* and the scene Australia. Lawrence collaborated in writing the book with Miss M. L. Skinner.

* * *

Dr. John A. Conway, New York State District Health Officers, reports, in the *American Journal of Public Health* for July, an outbreak of typhoid fever due to infected ice.

* * *

"When Is an Exhibit?" is a reprint from *The Transactions of the Seventeenth Annual Meeting of the National Tuberculosis Association.* It contains many good pointers on exhibits and their material and arrangement. Copies may be had upon application to the Association, 370 Seventh Avenue, New York City.

* * *

Professor Charles R. Stockard of Cornell University Medical College has in the April number of the *American Journal of Medical Sciences* an interesting article on the Relation of Alcohol to Racial Degeneracy. The writer believes that it is highly improbable that man has ever injured his normal resistant germ cells with alcohol. Nations that have used the strongest alcoholic beverages for many generations have outstripped other nations with less alcoholism in their history. Prof. Stockard attributes this to the elimination of those whose powers of resistance were not normal. He, like so many of the eugenists, is of the opinion that protection and preservation of the unfit are making for racial degeneration.

* * *

Dr. Alice G. Bryant, of the New England Deaconess Hospital, Boston, has in the *Medical Woman's Journal* for June an interesting and timely article entitled Phases of Heating and Ventilation That Might Occupy the Attention of Rhinologists and Otolaryngologists as well as All Members of the Medical Profession. The article is significant for New York City in particular, where heating conditions in apartment houses, public buildings, and especially public conveyances have been allowed to lapse into such inadequacy since the war economies proved that if it has to, the public will "stand for anything." Dr. Bryant's article is continued in the succeeding number of the *Journal.*

* * *

The School of Speech Education of Boston conducts during the Summer a free speech clinic, with classes for stutterers, the feebleminded, and those with whistling, phonetic and cleft palate defects.

* * *

A recent issue of *L'Echo de Paris* comments upon the fact that late statistics show that the Anglo-Saxons are the only people who patronize freely the French air lines. "This," according to the paper, "accords with their more sporting and adventurous temperament." The nationality of travelers who used aeroplanes in France last June was as follows: Americans, forty per cent.; English, thirty-four per cent.; Dutch, seven per cent.; French, six per cent.; miscellaneous, thirteen per cent.

* * * *

An article in the *Ice Cream Trade Journal* states that the art of making ice cream probably originated in Italy before 1600. Martha Washington, it is said, served ice cream on her table. There is a tradition to the effect that the first American ice cream seller's name was Hall and that he had a shop in Park Row, New York City, when its name was Chatham Street.

* * *

Travelers about to book passage for the Argentine are surprised to learn that among the various documents and certificates of which they must be possessed is one showing that they have not been in jail for the last five years. This requirement may cause hilarity on the part of the wouldbe passenger until he or she remembers that such a document may not be so easy to produce, regardless of the fact that the interested person has been entirely innocent of acquaintance with jails. The certificates must be obtained from the authorities of the locality where the passenger resides and must be written on the letterhead of police or court authorities. It must be viséd by the Argentine Consul. —*New York Times.*

* * *

The People's Institute Publishing Company of New York City has announced that it will issue in pamphlet form under the general title of "The Lecture in Print" stenographic transcriptions of the lectures of prominent scholars and scientists. The lectures are to be taken down in shorthand when delivered and later edited by the lecturer. The first series of lectures to be published in this way will be those given by Everett Dean Martin at the Cooper Union on "What psychology has to teach you about yourself and the world you live in." These will be followed by a series of lectures by Dr. John B. Watson on behavior psychology, and others by authorities on biology, evolution, etc.

* * *

The fame of the Municipal Matrimonial Advice Bureau, established in Vienna in 1922, has spread far beyond the boundaries of Austria and its popularity at home is rising rapidly. A German investigator has recently reported that the eighty-seven applicants for advice in 1922 rose to more than 500 in 1923, and every day the office receives letters from persons of many countries and nationalities asking for information and advice in matrimonial affairs. The institution was intended primarily to serve citizens of Vienna who are contemplating marriage and are not quite sure of their physical, mental and economical qualifications; however there are frequent calls for counsel as to preventing divorces and bringing about family reconciliations. The Matrimonial Advice Bureau emphasizes the necessity of good health, and, where an examination reveals traces of tuberculosis, venereal diseases or other serious ailments, the applicant is referred to his physician or to the sick benefit society of which he is a member. Through publicity and education the bureau hopes to bring about results that will permanently benefit the coming generation.

Abstracts from Current Literature

GASTROENTEROLOGY

Abdominoscopy.—O. P. Steiner (*Schweizerische medizinische Wochenschrift,* January 17, 1924) describes a technic, in which a puncture opening is made under local anesthesia above or below the umbilicus with a thick trocar. An endoscope of the size and form of a medium sized cystoscope is introduced into the opening and air is inflated into the abdomen through the endoscope. In this way the interior of the abdominal cavity, the various organs and pathological conditions are readily observed within the abdominal cavity. Very good vision is obtainable in this way. The author has never seen any harm resulting from this procedure.

Drainage of the Peritoneal Cavity.—Paul Albrecht (*Wiener Klinische Wochenschrift,* January 10 and 17, 1924) calls attention to the fact that drainage of the peritoneal cavity is practically impossible and should, therefore, be used as little as possible. Drainage with gauze and wicks should be avoided. In suppurative peritonitis, the source of the infection should be eliminated and every defect of the peritoneum should be covered over. After operations within the first two days, as long as the physiological protective apparatus is still functioning properly, it is better, as a rule, to close the abdominal cavity, provided the source of infection is removed, the hemorrhage is absolutely controlled, and all defects of the peritoneum are closed. Cases of diffuse suppurative peritonitis, that have lasted longer than five days, should be drained. Cases lying within these two conditions must be treated according to the individual experience of the surgeon.

Production of Formaldehyde by Intestinal Bacteria.—B. H. Shaw (*British Medical Journal,* March 15, 1924) found that the amount of formaldehyde produced by various intestinal bacteria varied between 0.0001 and 0.0015 per cent. The test for formaldehyde might be used to classify and identify bacteria, especially in the colon and proteus groups. There are various ways in which formaldehyde arising from bacterial action may interfere with cellular respiration which, arguing from the constantly observed association of confusional mental states with profound destruction of erythrocytes in cases of malignant malaria, and certain other facts bearing on states of acidosis, is, of the utmost importance to the maintenance of mental health. The treatment implies an attempt to replace the offending organisms by an innocuous type, which is very difficult. The Bacillus acidophilus may be used for this purpose but a recurrence usually follows. A more practical method is to give regularly liquid paraffin combined with occasional doses of salts and to restore the general tone to the system. The use of calcium salts might also be borne in mind.

Cutaneous Hyperesthesia in Acute Abdominal Disease.—Zachary Cope (*Lancet,* January 19, 1924) says he has found hyperesthesia in numerous cases of acute appendicitis, perforated gastric or duodenal ulcer, cholecystitis, cholelithiasis, primary peritonitis, salpingitis with pelvic peritonitis, acute tuberculous peritonitis, ovarian cyst wth twisted pedicle, renal colic, pyelitis, abscess of the spermatic cord, intestinal obstruction and acute dysentery. The author considers cutaneous hyperesthesia as an important means of assistance in diagnosis of acute abdominal disease. Since various disorders are accompanied by similar hyperesthesia it follows that increased cutaneous sensibility must not be taken by itself to prove the existence of any particular lesion. All the symptoms must be considered together before arriving at a diagnosis. Nevertheless, in acute disorders this particular symptom can almost always be taken as signifying inflammation or irritation of a viscus or of some part of the peritoneum. The extent of the hyperesthesia bears no direct or constant ratio to the extent of the lesion. General peritonitis may be entirely unaccompanied by cutaneous hyperesthesia, while appendicitis without any peritonitis may cause widespread bilateral cutaneous manifestations. Patients who have a reflexly active or hypersensitive nervous system are more likely to exhibit extensive hyperesthesia. Occasionally mental shock may have an influence. Sometimes removal of the cause leads to an almost immediate disappearance of the hyperesthesia, but quite frequently the skin only gradually returns to normal.

Significance of Oidium in Chronic Gastric Ulcer.—F. Merke (*Schweizerische medizinische Wochenschrift,* January 10, 1924) demonstrated the presence of the Oidium albicans in seventy-five per cent. of sixteen cases of chronic resected gastric ulcers and in twelve perforations from ulcer. He was usually able to produce typical oidiomycoses by maceration of the skin with a wet dressing and rubbing of the fungi into the skin. The maceration resulting from the action of the gastric juice in the gastric ulcer also favors the occurrence of the fungi, which fact may be of significance in the chronicity of the ulcer.

Hypercholesterolemia.—A. O. Wilensky (*Annals of Surgery,* November, 1923) in commenting on a case said he believed there were many factors which pointed clearly to the fact that the disturbance of metabolism leading to hypercholesterolemia was a fatigue phenomenon. Rest corresponded to the period of normal cholesterolemia. In times of superabundance, the release from the body of any excess of cholesterol beyond the quantity which the body, in a healthy state, could normally handle favored the recuperation of the fatigued function and restored the metabolic activity to a normal state. Such restoration to normal active conditions, i.e., the removal of excess quantities of cholesterol, could be accomplished by the drainage of bile, or by the curtailment, either partial or complete, of the replenishing supply of fat in the food source.

It was not to be assumed in any way that every case of pure hypercholesterolemia, in which the symptoms were referable to the disturbance of the cholesterol metabolism, should be treated by operation and relieved by the drainage of bile. Undoubtedly many of the disturbances were slight and were spontaneously corrected. Undoubtedly, too, many others could be relieved by proper dieting. Only a few seemed to be proper for surgical therapy, and, as knowledge increased, these, too, might grow less and less in number.

Chemical Blood Changes After Intestinal Obstruction.—R. L. Haden and T. G. Orr (*Surgery, Gynecology, and Obstetrics,* October, 1923), present the following conclusions:

1. Definite blood chemical changes are found in acute intestinal obstruction, manifested by a fall in the blood chlorides, often a rise in the carbon dioxide combining power of the plasma and a rise in the nonprotein nitrogen.
2. The fall in chlorides is considered the chief factor of this change and indicates that the chlorides may be utilized by the body as a protection against the toxic agent.
3. The administration of sodium chloride in larger doses than that supplied by physiological saline is indicated in acute intestinal obstruction as a means of directly combating the toxemia.
4. Since an alkalosis is frequently present in intestinal obstruction, alkalies should be administered with caution.
5. We have estimated that in the presence of the toxemia of intestinal obstruction sodium chloride at an initial dose of one gram to the kilogram of body weight should be administered. The blood and urine chlorides should be closely followed to estimate the subsequent quantity of sodium chloride needed to keep the chlorides at a normal level in the blood.

Pathology of the Acutely Inflamed Appendix.—In the twenty-seven cases examined by Leonard S. Didgeon and P. H. Mitchiner (*British Journal of Surgery,* April, 1924), the chief aerobic organisms isolated from the interior of the appendix in the first thirty hours of appendicitis were B. coli and streptococci. All except one streptococcus were nonhemolytic. The Bacillus welchii was present in four out of twenty-five acute cases. Bacillus coli were not obtained by blood culture, and the streptococci were found in only one case. In all cases recovery took place without complications. Bacillus coli infection of the urinary tract was present in three cases. Serological tests were made with the anticolon sera and with the isolated strains of Bacillus coli, with positive results in half the cases. Intestinal parasites were found in one of the acute cases, and in only one of the control cases of quiescent appendicitis (oxyuris). Appendix concretions consisted of fats, soaps, and

vegetable matter. Fats were demonstrated in the lumen, mucous lining, in the gland cells, in the lymph nodes of the appendix wall, and in the lymph glands draining the appendix in the quiescent cases. These findings suggest fat absorption from the lumen. In many of the acute cases the inflammatory process in the submucous and muscular coats was much more intense than the appearance of the mucosa led one to suspect. Evidence of chronic appendicitis was demonstrated in the wall of the appendix in some of the acute cases, although no previous history of appendicitis was obtained. In the chronic cases, and in the acute cases where evidence of previous inflammation existed in the appendix wall, the fibrosis involved the muscular coat, which was extensively disorganized. Spirochetes were found in two cases, and these patients had not been abroad.

Results of Operative Treatment of Ulcer Disease.—P. Clairmont (*Schweizerische medizinische Wochenschrift,* February 28, 1924), found that among a series of 1160 patients with ulcers of the stomach or duodenum subjected to different methods of surgical procedure the results were about the following: With the Eiselsberg method of exclusion of the pylorus too many ulcers of the jejunum appeared subsequently. The results with gastroenterostomy were good and bad in about the same proportions. The ultimate result depends considerably upon the nature of the disease rather than upon the technic of the operation selected. Resection shows the best results. The author's primary mortality in cases of resected duodenal ulcer amounted to six per cent.

Chronic Dyspepsias of Women.—A. J. Walton (*Lancet,* December 22, 1923) draws some tentative conclusions in regard to the cases of chronic dyspepsia in women that are due to prolapse of viscera caused by abnormally long mesenteries and the formation of membranes with an associated loss of muscular tone. He is in favor of administering medical treatment, which is to include physical exercises, combined with rest, general hygiene, dieting and medical treatment. Surgery should be considered only after such a course of treatment has proved to be ineffective and as an adjuvant to the medical treatment.

Use of the Duodenal Tube in the Treatment of Tapeworm.—Hans Schneider (*Wiener klinische Wochenschrift,* April 3, 1924) states that the advantages of the use of the duodenal tube are the avoidance of nausea and the effectiveness of smaller doses than those given by mouth. A cathartic is given in the evening and the next morning the duodenal tube is introduced on a fasting stomach. An infusion of kenna (five grams in fifty grams of water) is injected through the tube, and after fifteen minutes the same mixture plus two grams of extract of male fern and four grams of extract of pomegranate bark is also injected. The tapeworm is usually expelled within two hours. The sources of error are those of the passage of the duodenal tube, pyloric spasm, rolling up of the tube and gastroptosis.

Cholangitis Lenta.—E. Hedinger (*Schweizerische medizinische Wochenschrift,* April 3, 1924) reports five of his own cases of cholangitis lenta, under which term he includes cases of chronic, infectious cholangitis, without stones. The disease picture of this condition has many points in common with sepsis lenta. It is characterized by protracted periods of intermittent fever, icterus or subicterus, frequently an increase of bilirubin and biliary acids in the serum, bilirubin or urobilin and urobilinogen as well as biliary acids in the urine, painful swelling of the liver and a splenic tumor. In isolated cases there may be pronounced cirrhosis, resembling the Hanot type, with even a striking microscopical resemblance.

Congenital Pyloric Stenosis and the Rammstedt-Weber Operation.—Fedinski (*Monatsschrift für Kinderheilkunde,* April, 1924), asserts that there are two forms of congenital pyloric stenosis: 1, congenital hypertrophy of the pylorus, with almost exclusive or predominant involvement of the anatomical elements, and 2, the pure pylorospasm, induced exclusively through the nervous system. Various combinations of the two forms may exist. The particularly characteristic feature of the purely anatomical stenosis is the retention vomiting from the very beginning of the disease. The retention is favored by the previously occurring overdistension of the gastric wall. All the other symptoms may be observed in both forms of the disease. A demonstrable mass is undoubtedly a great aid in the diagnosis of pure stenosis, but unfortunately palpation is possible in severe emaciation. The Rammstedt-Weber operation is a great therapeutic aid and its indication varies from case to case. Surgical intervention is absolutely necessary in the cases of pure anatomical stenosis. In other cases, in which systematic therapy is futile and the case is becoming progressively worse, the operation is also justified, even in the purely nervous spasms. The operation should be undertaken, if the indication is clear, as soon as possible, while the child is still in possession of sufficient strength, and not *in extremis.*

Bilharzial Papillomatosis of the Rectum.—Robert V. Dolbey and Ibrahim Fahmy (*British Medical Journal,* March 6, 1924) state that the symptoms of rectal bilharziasis are constant tenesmus and the passage of blood and mucus. Treatment by tartar emetic destroys the living ova, but the papillomata and the consequent symptoms persist. The removal of the isolated papillomas by the knife or diathermy is unsuccessful, as they always recur. Injections of five per cent phenol, or other chemical agents, into the bases of the papillomata are equally unsuccessful. The only complete, thorough and permanent cure is obtained by the excision of the whole tube of rectal mucous membrane.

Hypertrophic Pyloric Stenosis.—Louis W. Sauer (*Archives of Pediatrics,* March, 1924), states that in the years that have passed since Ibrahim's classical monographs, much has been learned about the symptomatology, course and pathology of hypertrophic pyloric stenosis. The greatest achievements, however, have been in the domain of therapy. Most of the milder cases respond readily to dietary measures as thick cereal feedings, while the simple muscle-splitting operation of Rammstedt, when performed by experienced surgeons, has affected a great reduction in the mortality in the obstinate cases.

Laparoscopy.—Richard Zollikofer (*Schweizerische medizinische Wochenschrift,* March 13, 1924) states that laparoscopy is most serviceable in assuring the diagnosis of ascites, as in cases of cirrhosis cancerous metastases in the liver and general carcinomatosis, hypostatic congestion of the liver and perihepatitis. However, it has its limitations. It is harmless and easily borne only where a preliminary emptying of the ascitic fluid is possible, as otherwise the procedure might be dangerous. It is not applicable in changes in the gallbladder, appendix and adnexæ. The best medium for distension is carbon dioxide. Laparoscopy may be combined with radioscopy to advantage.

Essentials in the Treatment of Acute Abdominal Conditions.—George W. Crile (*Ohio State Medical Journal,* December 1, 1923), discusses such acute crises as are due to acute obstruction and the rupture or perforation of viscera with resultant severe hemorrhage or acute peritonitis. The type of patient to be considered here is the one who, on admission to the hospital, has a thready pulse and abdomen either distended and rigid, or filled with fluid probably blood. Such a patient is put to bed at once with a hypodermic injection of one quarter grain of morphine with one one hundred and fiftieth of atropine; he is immediately given large quantities of water (two to four thousand c.c.) by hypodermoclysis through two needles in the pectoral muscles; his blood is grouped at once and he is given a transfusion without being moved from his bed; he is immediately placed in a modified Fowler's position; large hot packs are applied to the abdomen and if he is vomiting he is given a gastric lavage. If there is improvement within the first hour, then a decompressing operation is done with the patient in his bed. The limited object of this decompression operation depends on the primary cause of the crisis, the imperative caution in each case is to stop the instant that objective is accomplished. Pursuant to this decompression, the patient's general management is in accordance with the following plan: 1, modified Fowler's position; 2, hot packs over the entire abdomen extending well down over the sides; 3, from two to four c.c. of water by hypodermoclysis every twenty-four hours; 4, transfusion of blood repeated if required; 5, except in gallbladder cases, morphine in repeated doses until the respiratory rate is down to ten to fourteen a minute; 6, maintenance of the utmost possible degree of negativity. Avoid all needless disturbance of the patient. Avoid any attempt to move the bowels in the acute stage of peritonitis. Avoid the continuance of morphine after the critical stage, but do not hesitate to give enough until the critical stage has passed.

Determination of Free Acid in the Gastric Juice by Titration of the Indicator.—H. Sahli (*Schweizerische medizinische Wochenschrift,* January 3, 1924) calls attention to the fact that the prevailing conception of the acidity values of the gastric juice have been revolutionized by the advances in physical chemistry, especially by the introduction of the concept of the hydrogen ion concentration. In general, the hydrogen ion concentration or actual acidity may be identified with the content of free hydrochloric acid in the gastric juice for all practical purposes and that of the combined acid with the idea of potential acidity. But the free acid cannot be determined by titration with alkalies because with them the free hydrogen ions are dissociated. In order to avoid this source of error, the author has elaborated a procedure which has given good results for years and has practically proved to be very accurate. A methyl violet solution diluted with distilled water shows a gradual deposit of violet over blue following green color on the addition of one tenth normal hydrochloric acid drop by drop. Ten c.c. of filtered gastric juice and the same amount of distilled water are mixed in two test tubes of the same size, each with 0.5 c.c. of a moderately concentrated and transparent solution of methyl violet. According to its content of free hydrogen ions, the gastric juice assumes a bluish to a greenish color. Then as much tenth normal hydrochloric acid is added from an accurately calibrated burette drop by drop to the pure methyl violet solution until the two fluids show the same depth of color. The hydrochloric acid content or hydrogen ion content of the methyl violet solution found at that moment (in this dilution the hydrochloric acid is as good as completely dissociated) corresponds to that of the gastric juice.

Chronic Intestinal Stasis.—W. Arbuthnot Lane (*British Medical Journal,* January 26, 1924) recommends a complete revolution in diet for the purpose of preventing the development of chronic intestinal stasis and its sequelæ, including cancer. In general, the diet should consist as much as possible of vegetable matter. It should be consumed largely in a raw state to avoid damage to the vitamines. Coarse indigestible material should be retained in order to increase the bulk of the intestinal contents, and the stimulating action on the reflexes. Food which may become offensive and poisonous when kept for a long time should be eliminated as much as possible. The consistency of the feces should be diminished and the frequency of the evacuations should be increased. Last, but not least, every possible endeavor should be made by mothers to suckle their infants for a sufficient length of time. As to the treatment of the existing condition apart from medical measures, such as the Curtis belt, paraffin of high viscosity, kaolin, and abdominal exercises, all operative measures on any portion of the gastrointestinal tract should be started by an examination of the last kink, and by the careful freeing of the bowel from its acquired attachment to the iliac fossa. The colon should then be examined in its entire length to make sure that no secondary constriction has developed, and particularly in the region of the splenic flexure. Any acquired band found controlling the lumen of the bowel should be carefully divided, and any raw surfaces deprived of peritoneum must be covered in accurately. An inflamed or controlling appendix or an ileal kink should be looked for and dealt with if present.

Principles of Treatment of Gastric Ulcer.—Charles Bolton (*British Medical Journal,* January 26, 1924), states that the two objects in view are: 1, to lessen the neuromuscular irritability of the stomach, more particularly of the pylorus, and thereby facilitate the emptying of the organ and restore the normal degree of duodenal regurgitation, and 2, to reduce the amount of gastric juice secreted. These two objects are accomplished by preliminary and subsequent treatment. In the preliminary treatment the patient is put to bed for six weeks so as to reduce the expenditure of energy and consequently the diet to a minimum and to reduce the work of the stomach. The food is then gradually increased to a full diet. The patient then gets up and is put on the subsequent treatment, masticating his food thoroughly and taking sufficient time and rest with his meals.

In the preliminary stage the food must be liquid or semisolid, finely divided, and free from irritants. An alkali is given during the later stages of digestion to neutralize the gastric contents. In the subsequent treatment the food must be such as to be easily disintegrated and peptonized, and free from irritants, such as decomposed fats, acids, and food accessories. In the preliminary treatment the foods are presented in the following order: milk, raw eggs, thin bread and butter, boiled eggs, cereals boiled in milk, pounded fish or chicken, mashed potato, sieved green vegetables, ordinary fish, chicken, mutton. The subsequent diet should contain an adequate amount of protein and carbohydrate, and as much fat as the patient likes in the form of butter, cream, boiled bacon and oil. Excess of fat may cause an aftersecretion of gastric juice. Rectal feeding should be resorted to only under two conditions: 1, bleeding from the stomach; 2, uncontrollable vomiting. Alkalies should be given, to replace the normal neutralization of the gastric contents by the regurgitation of the intestinal juices, about one and a half to two hours after each meal and also once or twice during the night if the patient is awake. The best alkalies are bismuth carbonate, calcium carbonate, magnesium oxide, and sodium bicardonate. Atropine has its uses, but takes a distinctly secondary place in the treatment. It relaxes the pyloric sphincter and permits of duodenal regurgitation. The only direct means of dealing with a chronic ulcer is to excise it; otherwise the aim of surgery is precisely the same as that of medicine—namely, 1, to facilitate the emptying of the stomach, and 2, to induce regurgitation of the intestinal fluids into the stomach, thereby neutralizing its contents in imitation of the normal duodenal regurgitation.

Examinations with the Duodenal Tube.—O. Winterstein (*Schweizerische medizinische Wochenschrift,* February 21, 1924) states that the duodenal tube in combination with instillations of magnesium sulphate is a very valuable diagnostic and therapeutic aid, but it frequently is of no avail. In acute cholecystitis, complete obstruction of the common bile duct, carcinoma of the biliary passages, cholangitis, typhoid fever, cholera, and in protozoal diseases the findings are valuable and interesting. The diagnosis of cholelithiasis and of chronic cholecystitis is rarely and only indefinitely established with this procedure. The diagnosis of duodenal ulcer is also uncertain. The duodenal tube is a valuable aid in pancreatic affections. It is especially valuable in cases where there is an absolute excretion of bile in abdominal differential diagnosis, where the duodenal, vesical and liver bile can be differentiated, when these contain no red or white blood cells, are sterile, or contain only an admixture of gastric flora. In such cases the biliary passages can be assumed to be healthy with great probability and they can be eliminated in the diagnosis. The same statement applies to the pancreas. The greatest value of the duodenal tube lies, therefore, in a process of exclusion. In some cases the duodenal siphonage gives valuable information, but this should always be subordinated to the history, the clinical findings, and the röntgenogram.

Bile in Metabolism.—E. Herzfeld and A. Haemmerli (*Schweizerische medizinische Wochenschrift,* February 7, 1924) recommend a technic for the determination of bilirubin, sufficiently accurate for clinical purposes. It consists of the mixture of a definite amount of the fluid to be examined (serum or urine) in increasing dilution with three drops of diluted Hammarsten reagent (mixture of concentrated nitric and hydrochloric acids). The dilution at which the bilirubin, converted into biliverdin, is still recognizable by the green discoloration is then read off. The bilirubin content is determined by a comparison with a dilution series of pure bilirubin. This technic is also applicable to hemolyzed serum, bloody body fluids, and extracts of organs, after the bilirubin has been changed by the addition of sodium bicarbonate into sodium bilirubin, which is soluble in alcohol, and after the albuminous bodies have been precipitated by absolute alcohol. The urobilin in urine, serum, and fecal suspensions is also determined on the same principle by the addition of an alcoholic zinc acetate solution. The diluting solution used is an alcoholic zinc acetate solution and the reading is made with an arc light or sunlight.

In the determination of biliary acids, the Pettenkofer test is modified to the extent that an eighty-four per cent. phosphoric acid solution is used in place of the concentrated sulphuric acid, in which test a deep blue to a bluish green color is developed in the presence of biliary acids. The solution used for comparison is made up by making a fresh solution of biliary acid alkalies from human bile. The delicacy of this reaction is marked.

End Results in Gastric Cancer.—After reviewing a large series of cases of gastric cancer, L. Schönbauer and Viktor Orator (*Wiener klinische Wochenschrift,* January 24, 1924) come to the conclusion that radical operations are usually impossible because patients come for treatment too late. In the majority of cases the extent of the involvement cannot be determined previous to operation and a large percentage of the cases in which a radical operation was done are, nevertheless, cured. Many a patient may be saved by early exploratory laparotomy, as is shown by the fact that twenty-seven per cent. of the cases in which resection was done were found radically cured on subsequent examination. Among the fatalities that were associated with operation, forty-four per cent. occurred after ether anesthesia, forty per cent. after local anesthesia, and sixteen per cent. when the operation was begun under local anesthesia followed by ether anesthesia. The indications for operation should be considerably extended, inasmuch as it was found that patients who were subjected to exploratory laparotomies lived six months longer and may have been improved by a radical interference. The author believes that a radical operative method, similar to that of the Wertheim operation for cancer of the uterus, which would include everything up to the hilum of the liver and the head of the pancreas, ought to be tried in cases of cancer of the stomach.

Bile Changes Caused by a Pressure Obstacle to Secretion; and Hydrohepatosis.—Philip D. McMaster, G. O. Broun, and Peyton Rous (*Journal of Experimental Medicine,* May, 1923), describe the changes occurring in the bile when obstruction hinders, but does not prevent, its flow through the ducts. With a progressively increasing obstruction, the fluid output lessened, and so even more markedly did that of cholesterol and of bilirubin. The final content of the stopped ducts was a colorless, limpid, "white bile," practically devoid of cholates and cholesterol. The authors discuss the liver changes following biliary obstruction, and show the essential likeness to the changes occurring under similar circumstances in glands in general and the kidney in particular. The major physiological factors concerned in the development of hydronephrosis and in the liver changes after biliary obstruction are identical. They therefore suggest the term hydrohepatosis as applied to the liver condition, not merely to designate, but to indicate the principles underlying its development. In clinical instances the likeness to hydronephrosis is often hidden because of the activity of the gallbladder to render the stasis bile dark and thick. There is then a concealed hydrohepatosis, differing merely by the character of the duct content, from the manifest hydrohepatosis, with "white bile," that is found when the gallbladder fails to act.

The Total Bile.—G. O. Broun, Philip D. McMaster, and Peyton Rous (*Journal of Experimental Medicine,* May, 1923), carried out their experiments with dogs permanently intubated for the collection of the total bile. In dogs fed the green bile or the liver tissue of herbivora, the bile later secreted frequently becomes green, changing from the previous yellow brown. The bile of dogs fed sheep bile that contains cholohematin comes to contain this pigment. When they are fed dog bile in quantity, a well marked increase in the output of bilirubin by the liver frequently follows. The authors believe that the increased bilirubin output after bile feeding is the result of an enterohepatic circulation.

Technic for the Bacteriological Diagnosis of Bacillary Dysentery.—L. O. Dutton (*Journal of Laboratory and Clinical Medicine,* April, 1924), presents the following routine procedure in order to arrive at a rapid bacteriological diagnosis of dysentery by a study of the feces. 1. Initial plating of feces, or preferably mucus from ulcers taken with a proctoscope and swab, on eosin methylene blue agar containing 0.5 per cent. each of lactose, saccharose, and glycerine. Reaction adjusted to pH 7.2. 2. Pick suspected colonies. Transplanting at least three to Krumwiede's triple sugar tubes for the purpose of checking the initial diagnosis and identifying the type. 3. At the time emulsify a mixture of several colonies in a drop of 1 to 30 polyvalent dysentery serum, mounted for a slide agglutination. Observe agglutination over a period of one hour. Partial agglutination at the end of that time is considered presumptive diagnosis of dysentery. 4. Transplant growth from the triple sugar tubes to dextrose, maltose, mannitol and sucrose with bromcresol purple as the indicator and observe acid formation forty-eight to seventy-two hours. The long period on the last step is to give time for the Flexner strains to ferment maltose. Even then the fermentation of this sugar is practically always slight. The reason for adding the saccharose and glycerine to the eosin methylene blue agar is to exclude from the probable dysentery colonies, those several intestinal bacteria that are nonlactose fermenting organisms, but that do ferment the added sugars. The fundamental point of the technic is the slide agglutination. A diagnosis can be made by this method at the end of twelve to fifteen hours.

Efficient Intestinal Antiseptic: Perchlorides of Mercury and Iron in Combination.—T. Stacey Wilson (*British Medical Journal,* February 16, 1924) found that fifteen minims each of liquor hydrargyri perchloridi and of tinctura ferri perchloridi, combined with a little glycerine and chloroform water, give good results in enteric fever, colitis, and dysentery, and in Addison's anemia. However, certain precautions must be observed: 1. A combination with albumin or alkalies will destroy the antiseptic value of this mixture, and it must therefore be given when the stomach is empty, and must also be combined with some drug which has more powerful affinities for alkalies (such as ferric perchloride) in order to prevent its neutralization by the alkalies of the duodenum. Where there is retention of the gastric contents owing to atonic dyspepsia or pyloric spasm its use is contraindicated owing to the certainty of the mercurial salt being converted into albuminate. 2. As the two perchlorides tend to irritate the gastric mucous membrane in some cases, the remedy is best given in circumstances which ensure as rapid a passage into the duodenum as possible. This object is best attained by giving the drugs fifteen or twenty minutes before meal times when the stomach is already becoming active in preparation for the reception of a meal. In acute cases, when definite meals are not given, the remedy can be given every four hours, and is usually quite well tolerated. As the continued use of this drug (iron) is sometimes followed by a loss of weight, patients who are taking it regularly should be carefully watched.

Anomalies of Intestinal Rotation.—N. M. Dott (*British Journal of Surgery,* October, 1923) presents the following conclusions:

1. The three stages of normal embryonic intestinal rotation are described. In the second stage the essential disposition of the intestines is attained.

2. Derangements of intestinal rotation are described and arranged under three heads: a, The first stage of rotation; b, the second stage (subdivided into three groups, nonrotation, reversed rotation, and malrotation); c, the third stage.

3. It is suggested that the cause of anomalies of the second stage is variation in size of the embryonic umbilical orifice.

4. The pathological consequences of anomalies of the second stage of intestinal rotation are described, and their incidence and relative frequency are estimated from the literature. Failure of sufficient intestinal fixation and consequent volvulus is found to be the typical lesion. Volvulus from this cause has its highest incidence in the first few days of life, and at this time a very extensive volvulus is characteristic. Volvulus of the ileocecal segment is the typical lesion in later life.

5. Three cases of volvulus due to anomalies of intestinal rotation are reported: a, Reversed rotation and volvulus of the ileocecal segment in an old man; b, nonrotation and volvulus of the entire midgut segment in a newborn child; c, malrotation and volvulus of the entire small intestine in a newborn child.

6. Three similar cases in the literature are briefly quoted.

7. Some special points in the surgical pathology of extensive volvulus in infants are considered.

8. The diagnosis of anomalies of intestinal rotation is considered: a, from the standpoint of abnormally situated appendicitis; b, from the point of view of recognition on the operating table; c, in cases of secondary volvulus, especially in the newborn.

9. An operative treatment by reduction and fixation is suggested for cases of extensive volvulus in the newborn, based upon an examination of two specimens of the condition.

NEW YORK, WEDNESDAY, OCTOBER 1, 1924

Medicolegal Notes.

PROMISE TO PAY BEFORE MEDICAL SERVICES RENDERED TO THIRD PERSON.

The Missouri Court of Appeals holds, Girdner v. Myers, 259 S. W. 150, that the rule that if the person performing services knows they are not for the benefit of the person making the request, and that he is under no legal obligation to pay therefor, he cannot predicate a claim against him unless he expressly promised to pay for them before the services were rendered, has no application to a case where the patient was taken to a hospital and the first act of emergency treatment given him occurred before the contract, this being infinitesimal compared to the rest of the services, and there being room for the belief that the defendant was pecuniarily interested in having the patient cared for and wanted that done.

IMMUNITY OF CHARITABLE HOSPITAL FROM LIABILITY TO PAYING PATIENT

Following Schloendorff v. N. Y. Hospital, 211 N. Y. 125, to the effect that charitable hospitals are not liable (except, perhaps, for failure to exercise care in selection) for the negligence of their physicians, surgeons and nurses in the treatment of patients, in the absence of a special contract or waiver by the institution of its legal immunity, the New York Supreme Court, Queens County, holds, Wilson v. New York Homeopathic Medical College and Flower Hospital, 204 N. Y. Supp. 175, that the fact that a patient, burned by the negligent application of hot water bottles by a nurse, paid $28 per week for room, board and services of nurses did not bar the hospital from setting up the defense of exemption, where the payment was merely a contribution, not sufficient to more than pay for the actual expense of the care of plaintiff.

ILLINOIS MEDICAL PRACTICE ACT

The Illinois Supreme Court holds, People v. Schaeffer, 219 Ill. 574, 142 N. E. 248, that the Illinois Medical Practice Act, 1890, discriminates against osteopathic physicians in favor of the graduates of the medical schools because it requires the graduate of an osteopathic school to continue his college education by becoming a graduate of a medical school before being examined for license to practice osteopathy and surgery; because he is required to study therapeutics of the allopathic or other medical schools, while a graduate of an allopathic school is not required to study osteopathic therapeutics; and if he attends a medical college he will be required to repeat studies he has passed through in his own school.

There is no provision in the act whereby a graduate of a college of osteopathy may be licensed to practice osteopathy and surgery, including midwifery, or whereby he may be examined to practice the same, unless he is also a graduate of one of the medical schools.

The statute is therefore held to tend to deprive the osteopaths of their constitutional right to practice surgery and to be void as to such physicians so deprived.

In People v. Graham, 311 Ill. 92; 142 N. E. 449, the same question was presented as in the Schaeffer case. Here the court said: "The authority of the Legislature, under the police power, to regulate and fix the qualifications of persons who practice medicine and surgery is not and cannot be denied. The Legislature may make such requirements as will qualify all classes of persons treating human ailments to thoroughly understand their profession and protect the public against those who are inefficient and unworthy. In the enactment of statutes for that purpose the Legislature may provide for classes, so long as the classification is general and bears a reasonable relation to the purpose sought to be accomplished; but any act of the Legislature which is merely arbitrary or discriminatory, where there is no substantial difference between the classes, and which abridges privileges of citizens or grants special privileges to classes, is in violation of constitutional rights."

"There was no provision of the act under which a license to practice surgery could have been given to the defendant. The right to such a license was limited to a class to which he did not belong, and as the law does not require a useless act to secure a right, the defendant was not called upon to apply for a license which could not be granted."

ACCIDENT CAUSING HERNIA

Where there was no testimony showing an accident except that of the plaintiff that he felt a sharp pain while operating a printing press, and the answers to hypothetical questions not based upon the facts, and no evidence that plaintiff suffered any strain, or slipped, fell or received any blow, or that the operation of the press was unusual or difficult, the New York Appellate Division, Sanders v. Faller, 205 N. Y. Supp. 285, held that no accident had been proved, and reversed an award for hernia. The court said that in the cases cited by the claimant there was either "heavy lifting," "a fall," "slipping with heavy weight," "overreaching," or "overbalancing," or some other form of a blow showing the causal relation.

PREMATURE DECISION AS TO COMPENSATION

The New York Appellate Division, in Levine v. General Electric Co., 204 N. Y. Supp. 777, holds that a series of findings and a statement that, if the claimant desires an operation, he will be entitled to compensation for the period of disability resulting therefrom, is not an award under the Workmen's Compensation Law imposing any liability on the employer. Should the time arrive when claimant is entitled to an award, the board may so determine.

VERIFIED REPORT OF PHYSICIAN REQUIRED IN NEW YORK

An unverified report by a physician, stating that the employee is dead and that his death was the result of traumatic pneumonia is not legal evidence in a workmen's compensation case under section 21, subd. 5, of the New York statute, which provides that "verified medical and surgical reports" shall be prima facie evidence of the facts therein stated in such cases. Paola v. Porter Bros. (N. Y. App. Div.) 205 N. Y. Supp. 281.

TAXATION OF HOSPITALS

The Tennessee Supreme Court holds, City of Knoxville v. Ft. Sanders Hospital, 257 S. W. 408, that a hospital maintained by physicians, having 65 beds, and being equipped with a research laboratory and a modern x ray outfit, and conducting a school for nurses, having an average of seven or eight charity patients, the remainder being charged substantial prices for their accommodation, was not exempt from taxation of its property under Tennessee Const., art. 2, §28, and Acts 1907, c. 602, exempting property belonging to "charitable, scientific, or educational institutions."

ACCIDENTAL DEATH WITHIN ACCIDENT POLICY

The Indiana Appellate Court holds, Hoosier Casualty Co. v. Royster, 142 N. E. 18, that death caused by the puncture by deceased of the lower bowel in using a tube for the introduction of medicine in treating hemorrhoids was not an accidental death occurring through external, violent and accidental means within an accident insurance policy.

Trustworthy!

The extent to which innumerable practitioners of medicine are today employing

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

whenever a dependable reconstructive tonic is called for, tells in no uncertain way of its therapeutic utility and gratifying efficiency.

During the thirty-five years this reliable tonic has been at the service of the profession, the quality of its ingredients and the unvarying character of the composite product have been consistently and faithfully maintained.

Thus it is easy to understand why the host of medical men who have learned how reliable it is in its character and results, not only take pains to order the original Gray's Glycerine Tonic Comp. (P. F. Co.), but also to see that their patients get no other!

Such care is well worth while, for it often measures the difference between success and failure.

The Purdue Frederick Co., 135 Christopher St., New York

Valentine's Meat-Juice

The **Power** of **Valentine's Meat-Juice** in **Quieting** the **Irritable Stomach, Aiding** the **Digestion, Restoring** the **Appetite** and **Sustaining** and **Strengthening** has been demonstrated by many **Medical Men** in the treatment of

Anaemia, Exhaustion *and* Debility.

Dr. R. Sarandeses, *Physician to the Provincial Hospital Oviedo, Spain:* "I had occasion to use VALENTINE'S MEAT-JUICE on a member of my own family and with excellent results. It is most agreeable to the sick and well, is easily prepared and administered, and for the young anæmic constitutes a superior remedy."

Dr. Lenoble, *Surgeon in Chief, Military Ward of the Hospital D'Argentan, Argentan, France:* "The powerful reconstituent, VALENTINE'S MEAT-JUICE, brought about a great improvement in the condition of the sick and wounded, whose long stay in the trenches had made them particularly anæmic."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,
Richmond, Virginia, U. S. A.

S 13

VALENTINE'S PREPARATION
NUTRIO PHERMIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Extraprofessional Activities of Physicians.—Dr. W. Moore Thompson in the *Illinois Medical Journal* for July, August, and October, 1923, outlines the work of medical men outside of their profession. Many of these men studied medicine but never followed the profession seriously. Among these were Goethe, Ibsen, and Schiller, the last of whom was for a time a medical officer in the army. Among physicians who were in active practice and at the same time litterateurs were Sir Richard Blackmore, Arthur Johnston, Mark Akenside, John Phillips, George Crabbe, Rabelais, Smollett, Oliver Goldsmith, Sir Thomas Browne, Dr. John Brown, Oliver Wendell Holmes, S. Weir Mitchell, and Conan Doyle. The famous "Delta" of *Blackwood's Magazine* was Dr. David Macbeth Muir, of Edinburgh; others who wrote were Thomas Gordon Hake, Drummond of Canada, Edward W. Watson of Philadelphia, James B. Naylor of Columbus, Ohio, and Charles Alexander Eastman, of Boston. The present poet laureate of England, Robert Bridges, was for twenty-five years a successful practitioner. Eugene Sue was a surgeon in the French navy; others who have done notable literary work together with their medical practice were Charles Lever, Samuel Warren, and J. G. Holland, founder and first editor of *Scribner's*, and later on the editorial staff of the *Century*.

Among physicians who have achieved fame as explorers were Charcot, Elisha Kent Kane, and Hayes. Among physician politicians and statesmen have been Clemenceau; Jameson of South Africa; Sun Yat Sen, president of South China; Sir Charles Tupper, who was premier of Canada; and General Leonard Wood.—*Annals of American History.*

Smoke, Fog, and Health.—It has been said that the fogs of England are a byword among the nations. This may be true, but the fact remains that the atmosphere is polluted by smoke in industrial centres in other parts of the world, although the domestic chimney is perhaps a more predominating source of smoke in England than elsewhere. It is because of this smoke that a mist—such as naturally occurs in rural districts—is transformed over the city into a thick, choking cloud, well named "pea soup" in many instances. It is difficult to estimate exactly the damage to health that smoke pollution produces, but the occurrence of dense fogs in England towards the latter part of a year enables some comparisons to be made. During the week December 1 to 8, 1923, fog was more or less prevalent in London. The official figures for deaths from certain diseases of the respiratory system (bronchitis and bronchopneumonia) showed a sudden increase for this period. Thus for a week in the middle of November the number of deaths from these two causes was 106, while during the week in question this number had increased to 303.

A campaign for clean food and pure water has the support of all persons who are working for the improvement of health for the nations of the world. It has been pointed out that a man consumes daily two to three pounds of food, four to five pounds of water and forty pounds of air. Yet people may everywhere pollute the atmosphere with comparative impunity. (It is true that there are certain restrictions in England concerning industrial chimneys.) In the winter months at least seven eighths of the sun's power are shut off by smoke from the centre of London. The apparatus which measures this records only the heat rays of the sun, but the ultraviolet rays which have been shown to be so important in the treatment of rickets and tuberculosis are shut off to an even greater extent.

The presence of coal smoke with its irritant particles is therefore a positive danger in the serious effects produced upon the respiratory organs. It robs city dwellers of the curative rays of the sun, and by the moral effect of gloom it increases depression and fatigue, and lowers the body's power of resistance.

If smoke pollution is to be abolished, two main lines of attack are open. The one is the production of a smokeless fuel which shall be both within the financial reach of the poor and economically of value to the manufacturer. The other is in evolving electrical heating and lighting power which shall be equally available for all.

Smoke is a definite enemy of health, and if, as is the opinion of experts, pollution of the atmosphere can be prevented, then all health workers must see to it that they take their share in hastening the solution of this vital problem.—(*The World's Health*, July, 1924.)

Trachoma.—This dread eye disease of the Orient and most ancient of recognized human ills is seen as a world menace by Dr. R. T. Uhls, of Kansas City, noted American eye specialist, who has returned to this country after an exhaustive survey of the disease throughout the Levant in behalf of the Near East Relief.

Dr. Uhls, after three years of service as eye specialist of the relief organization, began his final survey six months ago, travelling from Armenia across Persia and Turkestan to Afghanistan and the Chinese border. Because of his success in combating the disease in Armenia, the Moscow Government, which controls most of the territory in which his researches were conducted, opened public health records to him and ordered the cooperation of native physicians.

Infection runs higher than fifty per cent. of the total population in all areas visited, according to Dr. Uhls, with a very large proportion of blindness as a direct result of the disease. The demoralization of native health services since the war and the tremendous lowering in the standards of living caused by invasion and periods of famine are chiefly responsible for the marked increase in trachoma.

"Relief measures also are contributing indirectly to the fight against trachoma in Armenia by the improved methods of sanitation which Americans have introduced and to the increased interest in healthier living conditions which they have awakened in the people," Dr. Uhls said. "With the cooperation of the Government, a public health service has been organized that is carrying on an effective educational campaign among the peasants in the outlying districts and the more ignorant people in the slums of the cities."

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

The Retention of Intestinal Poisons

is now recognized as the chief factor in the causation or aggravation of many acute and chronic ills. The immediate removal of these poisons is always imperative, and to accomplish this there is no remedy more effective than AGAROL COMP.—a delightfully palatable and well balanced preparation of mineral oil, agar-agar and phenolphthalein.

AGAROL COMP. not only assures prompt and satisfactory elimination, with gratifying relief from the influence of retained poisons, but presents the further advantage of promoting permanent restoration of normal bowel function.

Thus its ingredients mix thoroughly with the bowel contents—the oil softening and lubricating the fecal mass, the agar-agar retaining moisture and increasing its bulk, while the phenolphthalein furnishes the initial impulse that starts the peristaltic wave.

Not only will satisfactory elimination be accomplished without delay, but as a result of the continued effect of Agarol Comp. on the secretory and mechanical processes of the bowel, regular evacuations will follow naturally without requiring the aid of any further medication.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances; not habit forming.

Bottle and literature mailed gratis, upon request.

Mortality Record of the First Six Months of 1924.—The first half of 1924 has probably registered a lower deathrate than was ever experienced for the first six months of any year in the history of the United States and Canada. This is indicated by the mortality records of the more than fifteen million Industrial policyholders of the Metropolitan Life Insurance Company, published in the company's statistical bulletin for August.

Among the most gratifying items in the record for the half year are the declines in the mortality from the diseases which are of interest in public health and insurance medicine. The typhoid fever rate is still falling and there is promise that a new minimum will be registered in 1924. Diphtheria mortality in the Industrial population has been running lower than ever before. Scarlet fever and whooping cough, it is true, show practically the same death rates as for the corresponding period of last year. There has been no general prevalence of epidemic influenza thus far. The mortality from lobar pneumonia decreased markedly among the white policyholders and slightly among the colored. Bronchial pneumonia, it is true, caused more deaths than during the same period of last year; but this, again, was due to the relatively high coverage of infants.

An encouraging item is the further decline among white women in the mortality from diseases incidental to pregnancy and childbirth and, more particularly, from puerperal septicemia. Unfortunately, this improvement did not obtain for colored women.

Attention has been directed in several recent issues of the *Bulletin* to the decline in the diabetes rate which began coincident with the increasing use of insulin in 1923, and which followed an uninterrupted rise during the preceding four years. The rates for the first six months of 1924 supply still later data and even more convincing evidence of the extent of the fall in the diabetes death rate, which amounts to 21.6 per cent. among the white policyholders and to more than ten per cent. among the colored.

Little encouragement is to be derived from the cancer mortality figure. While a slight decline was recorded among the whites the death rate increased to an equal extent among the colored. The combined rate, however, is a little lower than that in evidence at this time last year.

The number of deaths recorded from alcoholism was 236 with a death rate of 3.0 per 100,000. This may be compared with 241 deaths during the first six months of last year and a rate of 3.3. It is still too early to determine whether the peak in the rise of the alcoholism death rate, since 1920, has been reached. Unless, however, an unexpectedly large number of deaths are recorded during the final six months there will be no rise in the rate this year as compared with last.

Deaths from acute poisoning by wood and denatured alcohol appear to be decreasing in the Industrial population. Only eight were recorded during the first six months of this year as compared with twenty for the same period of 1923. Cirrhosis of the liver, which is closely associated with alcoholism, caused 475 deaths, as compared with 435 deaths during the first half of last year. The death rates were identical, however, being 6.0 per 100,000 for each year.

Teratoid Tumors and Teratology

W. ROGER WILLIAMS, F.R.C.S.,
Somerset, England

The weakest spot in the chain of knowledge relating to tumors is the link which is called teratoid.

It may be said that teratoid tumors are to tumor science in general what the *residua* of chemical processes are to chemical science in general; that is to say, a store of potential discoveries and unappreciated facts of great value and significance for scientific and practical purposes. Of all the methods of scientific investigation this is one of the most fertile in unexpected results, since it often brings to light relationships that would otherwise have escaped notice, of which our study of the subject has revealed many examples. For instance, the great complexity of the morphological basis of these tumors—malignant and nonmalignant—shows that their properties concentre in morphological complexes, in which derivatives of all the germinal layers commonly participate, so that the process of tumor formation, from this viewpoint, can hardly be regarded otherwise than as a *morbid variety of growth.* It is just the same with the secondary and recurrent manifestations of malignant teratoid tumors, which commonly reproduce the morphological complex of the primary tumor, rather than any single tissue element.

It seems likely then that in this confused heap of miscellaneous teratoid items, the result of haphazard accretions from many and various sources during the last century or so, the keystone of the arch of tumor science in general may be found.

At any rate, these teratoid tumors present special features of a remarkable kind—genetical, histological and biological—which ought not to be ignored, as hitherto, when the subject of tumor formation in general is under consideration.

But, profitably to explore these mazes, a sound method—based on clear perception of the natural interrelations of the constituent parts of the problem to one another and to the *ensemble* of the subject—is essential; for otherwise, owing to the multiplicity of incongruous details, we should soon be engulfed in the prevailing confusion. This we claim to have provided by our discovery of the natural affinities of teratoid tumors, and their grouping in accordance herewith, which gives the much needed unity of conception. It is time to study these immense stores of *disjecta membra,* to combine and correlate the details and to consider the general aspects of the subject, as Aristotle has it, "with a head on," so that from this new viewpoint a higher plane of progress may be attained.

In pursuing our investigation in this spirit, and having examined everything of importance relating thereto, so far as our knowledge goes, we hope thus to open up and establish a new branch of science wherein of course much still remains to be done.

With these preliminary remarks, we enter on the systematic study of teratoid tumors without any prepossessions, except as to their blastogenic origin, which we need not here pause to justify.

The term teratoid is so ambiguously employed that we may as well state the sense in which we use it. For us the portent indicated by τέρας, is a parasitic fetus or some derivative thereof, however imperfect.

CLASSIFICATION

A teratoid tumor is therefore either an included parasitic fetus, some part or parts thereof, or a growth derived therefrom. For the sake of convenience the following varieties may be discriminated:

1. The *teratoma,* which comprises an easily recognizable fetus or fetal parts, more or less included in the tissues of the autosite.

2. The *teratoid,* in the strict sense, which consists of a medley of various included fetal structures chaotically disposed. Derivatives of all the germinal layers are generally comprised therein, but in degraded specimens some of these may lack.

3. The *dermoid,* a clinical term, applied to certain teratoid growths in which tegumentary structures are predominant. Heterotopic tegumentary cysts otherwise derived may be discriminated as cutis cysts.

Teratoids then, as the etymology implies, are derivatives of more or less imperfect fetal formations parasitically implanted in the autosite. Their origin can be traced to some product of asymmetrical diplogenesis or rarely to some higher variety of polygenesis. Thus the origin of these growths goes back to the earliest phases of developmental exegesis. This being so, as our studies of all the types show, it follows that their genesis is but a phase of teratogenesis.

It accords with the foregoing that teratologists have always had a better understanding of the nature of teratoid growths than pathological anatom-

Copyright, 1924, by A. R. Elliott Publishing Company.

ists, who have based their conclusions too exclusively on histological details.

Thus, I. G. St. Hilaire (1)—the father of teratology—long ago wrote of ovarian teratoids: *"Comparez le parasite vivant isolément dans l'ovaire avec l'individu parasite d'un hypognathe, et vous trouverez en effet que la même déscription peut convenir à l'un et à l'autre."*

If pathological anatomists are only now beginning to realize the correctness of this conclusion for all the local varieties of teratoid growths, we must ascribe this backwardness to the neglect of teratological studies which has characterized the last half century, for such are the interrelations of the biological sciences that none of them can be brought to perfection while their congeners are neglected.

Therefore if progress is to be made in these matters, to pathological anatomy we must join teratology, which is as it were its prolongation.

However different in their several degrees, diplogenetic formations nevertheless constitute a continuous series; so that between such highly evolved types as conjoined twins and such incomplete manifestations as slight doubling of either end of the longitudinal axis, every intermediate gradation is represented. Or, otherwise stated, as in Vrolik's terms: "There can be traced such degrees and modes of deviation from singleness as pass, without one abrupt step, from the addition of a single ill developed limb to the nearly complete formation of two distinct beings."

NATURE OF TERATOID GROWTHS

In like manner, we have traced similar genetic connection between the parasitic forms of diplogenesis, and all the chief types of teratoid growths.

A necessary consequence of the foregoing is that all teratoid growths are of the same nature, genetically and morphologically, and such differences as they manifest *inter se* are of degree and not of kind. Teratoids of the sexual glands, for example, are not specifically different from their intraabdominal congeners of the mesenteric vicinity, as Wilms maintains.

By seeking out and coordinating the many miscellaneous items relating to teratoids in accordance with the foregoing considerations, we have thus succeeded in reconstructing the series for each type; and so have been enabled to determine their natural affinities—the only sure foundation on which to build. We can thus present, for the first time, a uniform scientific basis for the study of all teratoid tumors.

LOCATION OF TERATOID GROWTHS

It may be gathered from the topographical study of teratoids that these growths concentre in certain definite localities. Large numbers are found in the sacrococcygeal region, especially posteriorly and inferiorly.

Directly continuous with the foregoing is a group which occupies the dorsal part of the pelvis, in front of the sacrum and coccyx.

In many instances the same teratoid is found in both presacrococcygeal and postsacrococcygeal sites.

Next we come to the very numerous *intraabdominal* teratoids, which connect with the dorsal pelvic group. It is with these intraabdominal examples that the teratoids of the *sexual glands* must be included. All the members of this intraabdominal group, including those of the sexual glands, concentre in the vicinity of the primitive mesentery, and they are always extraperitoneal. Detailed study of these linked groups of teratoids points unmistakably to the conclusion that they all originate in the vicinity of the posterior or lower end of the nascent body axis.

As the evolving axis elongates and descends, some of these primitive teratoid germs are carried down therewith into the dorsal part of the pelvis, and others into the sacrococcygeal region. Those remaining behind foregather in the mesenteric region. Thus, any part of the tract of this *descensus,* from the region of the primitive mesentery to the sacrococcygeal region, may harbor these teratoid germs.

ORIGIN OF TERATOID GROWTHS

As to the particular types of polygenesis whence these local teratoids originate, thorough exploration of the subject has convinced us that these may be reduced to two, viz., the pygopagic and the dipygic (*duplicitas posterior*). The teratoids of this group form a numerous company.

Here mention may be made of another small group of teratoids which also originate in the vicinity of the lower end of the body axis, to wit, those found in the *ventral* part of the pelvis, which concentre in the pubic vicinity. These are derivable from ischiopagic and dipygic diplogenesis, etc., as our series of instances show.

Of the remaining teratoids, most originate about the anterior end of the nascent body axis.

Of these, two chief allied groups may be discriminated—*the cephalic* and the *cervical.*

With regard to the cephalic teratoids, most concentre about the basis cranii, whether within or without the cranium or in intermediate positions.

These are derivable from parasitic forms of *duplicitas anterior,* or from similar forms of the "Janus type" of diplogenesis, as we have found by adducing the intermediate links of the chain of connexion.

Another considerable group of cephalic teratoids concentres about the buccal and facial regions, and these are similarly derivable from the foregoing.

Yet other cephalic teratoids, less numerous than either of the groups mentioned, are met with; which are derivable, as our serial studies show, by adducing the intermediate links, from craniopagic diplogenesis. Of these we discriminate frontal, parietal and occipital varieties.

There is analogy between these craniopagic types of the anterior end of the body axis, and the ischiopagic types of the posterior end of the body axis.

As for the cervical teratoids—which occur in median as well as lateral sites: at upper, lower, as well as at intermediate levels—most of these, as our investigations show, are derivable from parasitic forms of duplicitas anterior, left behind by the elongation of the nascent body axis; and others are traceable to asymmetrical forms of the "Janus type" of diplogenesis.

Finally, we come to the *thoracic* teratoids, which are found without as well as within the thorax, and even in intermediate positions.

Many of these we have traced to the same forms of diplogenesis as their cervical congeners, of which

they may be regarded as an extension. This specially applies to those teratoids which concentre at the upper part of the thorax, about the base of the heart and its pericardial sac.

The remaining thoracic teratoids, as our researches show, are mostly derived from parasitic forms of sternopagic and xiphopagic duplicity.

We have traced the stages of this genetic connection of the local groups of teratoids, with the above mentioned types of diplogenesis, by adducing the intermediate links; but to give the details would require a special treatise, which we hope will see the light, when the economics of production are more favorable.

For each group, the chief rallying points of our rationale are as follows:

1. Conjoined twins or symmetrical duplicitas; 2. externally attached parasites; 3. teratomatous or included parasites; 4. teratoid and dermoid tumors.

Auscultatory Percussion and Palpation

L. NAPOLEON BOSTON, M.D.,
Philadelphia

The art of percussion over a solid viscus, while ausculting over such organ by aid of a small stethoscope, is by no means new, and was employed by Clark in outlining the heart as early as 1840. This method was first practised in the Philadelphia General Hospital (Blockley) in 1896 by the late Dr. Frederick A. Packard, then visiting physician to the Philadelphia and Pennsylvania Hospitals. Serving as Packard's resident physician, I was invited to work with him in perfecting this method.

Neither this method as used in 1896 nor any of its modifications now in vogue for the detection of the calibre of the intestine (size of cecum, colon, stomach and displacement of such viscera) were ever suggested by Packard. In fact auscultatory percussion was then thought to be valueless in examinations of the lungs and other air containing viscera.

Measurements of the heart were obtained by auscultatory percussion by such clinicians as Alonzo Clark and George P. Cammann as early as 1840, and Stengel described accurately Compte's method of stroking the skin in 1897. Stengel in his article stated that he had been using auscultatory percussion in the outlining of solid viscera for a period of five years (four years before Packard's work), and regarded it as a most valuable method. In referring to Compte's method Stengel gave the following: "The method of Compte's is therefore, I believe, wholly useless." Stengel further described, at length, the difficulties in the employment of auscultatory percussion for outlining the stomach, and hollow abdominal viscera, as he found it in 1897. It might be well to add that practically all these objectionable features have been overcome, and today we find auscultatory percussion and palpation the most reliable known methods for outlining and detecting abnormal conditions of the air containing viscera.

The late D. D. Stewart, in discussing the paper of Stengel in 1897, made mention of the fact that he had found auscultatory percussion the most reliable method of determining the lower margin of the stomach. I find no record of an attempt to outline the hollow viscera by means of the x ray until 1900 to 1902, fully three years after Stewart's observations, when it was found possible to give an imperfect outline of the stomach. Harbersohn described in 1902 a technic through which he was able to define the boundaries between the upper and lower lobes of the lungs by auscultatory percussion.

Andrew H. Smith places the bell of a binoral stethoscope in the patient's month and when the lips were closed tightly and the nostrils closed he conducted percussion over the lung, and obtained data of unquestionable value. Probably the earliest article referable to auscultatory percussion in pulmonary disease was published by Demissy in 1876, *Auscultatory Pletessimetrique.*

In 1897 and 1898 the writer began to modify Packard's original technic, and used the tuning fork, and different makes of stethoscopes for the recognition of pathological states of the air containing viscera. My resident physician, Alexander, in 1917 designed a special stethoscope, with two parchment diaphragms for use in the recognition of early disease of the apices of the lungs.

Auscultatory palpation (Compte's method), was employed first by me in 1897 and within the course of two years it was perfected to a degree which gave this combined physical method (stroking the skin and ausculting) a prominent position in the outlining of the stomach, colon and consolidated areas of the lung. My first thrilling experience came in 1898 when by the use of auscultatory palpation (stroking the skin), I outlined the pericardium, in a case of pneumopyopericardium. Results were confirmed by autopsy at the Philadelphia General Hospital.

I have found that the various modifications of auscultatory percussion and auscultatory palpation, when properly employed, give data regarding the size of both solid and air containing viscera not equalled in clinical value by any other known diagnostic method; and only approximated by röntgen ray findings. In a study of the lungs, auscultatory percussion and auscultatory palpation provide data far more reliable than röntgenographic records.

In 1914 Anders and Boston (*Diagnosis*) gave liberal consideration of this physical method, e. g., "This physical method combines percussion with auscultation by means of the stethoscope, and is by far the most practical method for the outlining of various diseased portions of the lung, and for ascertaining the size of solid viscera."

Fig. 1

Fig. 2

Fig. 1.—Cardiac diameters. Transverse leading from beyond the right border of the sternum to the left axilla. Right oblique leading from the uppermost area of cardiac dullness beneath the sternum to the apex. Left oblique leading from the superior left border of the heart to the ensiform. The right oblique diameter is increased most in left ventricular hyperthrophy. The left oblique and transverse diameters are increased in right sided dilatation. The diameters become of approximately equal length in acute cardiac dilatation. Percuss from below, the apex upward along the right oblique cardiac diameter to determine the lower extent of the apex. The stethoscope may be placed over any other portion of the heart, and percussion applied to determine heart boundary at any selected point.

Fig. 2.—Stroking the skin with a delicate file at the beginning of the right oblique cardiac diameter to determine this border of the heart. The left oblique extending from the left shoulder to the ensiform cartilage and the transverse diameter leading from the right border of the sternum through the nipple to the left axilla are also shown. Note the triangular area at the centre of the precordium (absolute dullness).

Fig. 3

Fig. 4

Fig. 3.—The area where the heart apparently overlaps the liver (accurate determination of hepatic and cardiac dullness). Stethoscope bell may be placed over any portion of the heart. Start percussion over the liver, and avoid bony structures, until the lower border of the heart is approached. By placing the stethoscope bell over any remote portion of the liver, percussion may be made across the body of the heart to determine the upper border of the liver at this point.

Fig. 4.—The tuning fork, while vibrating, is first placed over the skin of the chest, above the nipple, then advance downward on the nipple line in the same manner as though percussing. The stethoscope should be placed over some portion of the liver. When the tuning fork reaches the upper margin of the liver a marked change in sound is detected. The tuning fork can be used in a similar manner in the study of any solid viscus or tumor.

TECHNIC FOR EMPLOYMENT OF AUSCULTATORY PERCUSSION

1. Adjust the stethoscope bell approximately at the centre of the organ to be outlined, thus permitting the bell to correspond to the hub of a wheel, and consider the periphery of the organ, or felloe of the wheel, to surround an area extending some distance from the bell of the stethoscope and beyond the margin of the organ under study. The spokes, or radii lead from the hub outward to the line transcribing the outer circle. (Percussion is to be made along the line of these radii) (Fig. 1). The stethoscope bell is applied either over the centre of the organ or at a remote point on one radius.

2. Begin percussion away from the bell (outside the organ under study) and continue directly along one radius (after every stroke, lift the finger from the chest wall, and advancing it half to one inch toward the bell of the stethoscope) (Fig. 1).

3. Strike but a single stroke at one location on the chest. Do not hit your finger two or more times when it is located at the same area, as this gives confusing notes.

4. Make your percussion strokes of the same force, and time, in the same manner as though you were striking the keys of a musical instrument. Change in note is more easily appreciated when percussion strokes are rhythmic.

5. Whenever there is a sudden change in the percussion note obtained through the stethoscope, mark this point on the chest wall and again start at the rim of the wheel and percuss up to the same point as previously marked. In the event the change is again audible at this same point, some solid organ or tissue underlies the area where such change is detected.

6. Percuss along radii from different directions—mark each point where the percussion notes change, and thus crudely map out the organ in question (Fig. 1).

7. Place the stethoscope bell at one of the marks on a radius where the note changes—start percussing from outside the original wheel (outside the margin of the most distant part of the organ in question), and advance toward the stethoscope, and at the same time toward the further position of the consolidated area. The object is to reach the area where the note changes at the most distant point from the bell. Should the note change where it previously did, then both this marking and the one where the bell is located are corrected—(method of proof).

8. After having proved the first marks on the spokes of the wheel to be correct draw a line con-

Fig. 5

Fig. 6.—Percussing from above downward to determine the upper border of the liver, in the midclavicular line. The stethoscope is placed at the lower edge of liver dullness.

Fig. 7

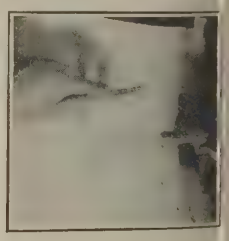

Fig. 8

Fig. 7.—Stethoscope placed over the centre of the liver, percussion is made from the left axilla advancing toward the left nipple line. This is the only known physical method through which we are able to determine the extent (to the left) of the left lobe of the liver.

Fig. 8.—Stroking the skin while listening to determine the lower border of the spleen. (Spleen always between ninth and eleventh ribs.)

necting these marks on the radii and thus outline the actual size of the solid organ.

9. Never continue percussion over the solid organ, or the solid pathological area you are endeavoring to outline.

10. Stroking of the skin and the use of the tuning fork, while listening, are delicate methods, and have herein been described in detail (see Figs. 2, 4, 11, 14, 18).

SOLID VISCERA

Heart.—In ascertaining the exact size of the heart only a moderate amount of experience is required. I have found that students learn quickly to outline the heart by auscultatory percussion. It is therefore suggested that the student first learn ordinary percussion, and later take up the subject of auscultatory percussion.

In outlining the heart the foregoing statements set forth clearly the technic to be employed, as well as the various precautions necessary. The accompanying illustrations (Figs. 1, 2, 3) will serve to explain the various steps in the technic.

Auscultatory percussion enables the clinician to determine the exact size of the heart, and to map out the edge of the organ that is overridden by the lung. This means of ascertaining the size of the heart is not new, it was employed by Clark in 1840, and has since been found to be the most valuable, practical means of outlining this organ.

The lower portion of the heart that rests upon the upper surface of the diaphragm and is in contact with the superior surface of the liver can be readily separated from the liver at this particular point, as is shown by the illustration (Fig. 3).

New growths of the mediastinum and aneurysm are also detected by auscultatory percussion and their exact size and shape are readily determined. Mediastinal new growths are quite easily separated from the heart by the technic given to distinguish between areas of liver and heart dullness. Dilatation of the aorta has been detected by auscultatory percussion, and I have repeatedly confirmed this finding by x ray study.

One is often called upon to differentiate between pleural effusion and cardiac dilatation, and I have also found auscultatory percussion a reliable means for deciding this differential diagnostic point. In a case recently seen in the Philadelphia General Hospital, it was found possible to outline the pericardium in pericardial effusion, and at the same time to determine by both ordinary percussion, and by auscultatory percussion, the upper boundary of a left pleural effusion.

In 1897 Stengel placed great stress upon the fact that he was able to separate the lower boundary of a dilated heart from the upper surface of an enlarged liver through the use of auscultatory percussion.

The dimensions of the pericardium when filled by either liquid or air or gas can be accurately determined by auscultatory percussion. When air is

FIG. 10

FIG. 9.—The stethoscope may be held against the spine while percussion is made over the corresponding areas of the lung. The author has adopted this portion of Alexander's method in routine work, and believes it to be indispensable.

FIG. 10.—Alexander placed the bell of his special stethoscope over the sternum holding the hand tightly over the instrument and allowing the index and second fingers to cover the apex of one lung, while the thumb is shifted over a corresponding area of the opposite lung. The slightest difference in the percussion note over the apices is detected through this method.

FIG. 11

FIG. 12

FIG. 11.—Stroking the skin while a stethoscope bell is placed over some portion of a consolidated area makes it possible to determine the exact extent of pulmonary consolidation and infiltration.

FIG. 12.—Stethoscope bell placed over the stomach while percussion is made from the left axilla, advancing downward and to the right, to determine the extent of the stomach in this region.

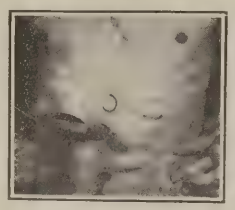

FIG. 13

FIG. 14

FIG. 13.—Stethoscope bell placed near the pylorus, represented by a circle, while percussion is made from below the fundus upward to determine the lower extent of the stomach; patient standing. The note of stomach tympany obtained by auscultatory percussion is distinctive, independent of what portion of the stomach is covered by the bell of the stethoscope.

FIG. 14.—Stethoscope bell located near the left inferior border of the stomach. The tuning fork while vibrating causes a characteristic note when placed upon the abdominal wall overlying any portion of the stomach. Practice sufficient to educate the operator's ear to the characteristic sounds heard when the tuning fork is employed in the study of the stomach, colon and lung, is necessary.

FIG. 15

FIG. 16

FIG. 15.—The descending colon has a fixed point just within the left anterior superior spine. Percussion at this point produces a characteristic colonic tympany when listening with a stethoscope bell placed over any other portion of the colon.

FIG. 16.—The colon ordinarily rises high in the left anterior axiliary line, an elective point to place the stethoscope bell when percussing, from the right flank advancing toward the umbilicus, to determine the right border of the ascending colon or the cecum.

present in the pericardium the percussion strokes should be very light, lest too much sound result in confusion. Stroking of the skin (Fig. 2) by means of a fine file is preferable to percussion in studying the pericardium. I have found the tuning fork to give unmistakable physical evidence in this connection.

Tuning fork.—The technic for the employment of

Fig. 17

Fig. 18

Fig. 17.—Percussion from the right flank, advancing to the left, to outline the right border of the ascending colon. Note transverse line at umbilicus—dotted line outlining colon.

Fig. 18.—Stethoscope bell placed over the right border of the ascending colon; stroking the skin with a fine file, advancing from left to right, to determine the left border of the ascending colon.

the tuning fork differs in no way from that given for auscultatory percussion (Fig. 4) except that in place of percussing, the tuning fork while vibrating, is placed upon the surface of the body, advancing gradually toward the stethoscope bell, in the same manner as outlined for auscultatory percussion and auscultatory palpation (avoid bone conduction). The tuning fork gives such a decided difference in sound when it reaches a solid viscus, and when it travels from a surface overlying a hollow viscus of a smaller or greater calibre (colon to stomach) that this sign is immediately apparent even to the untrained ear. The tuning fork may be advantageously employed in the outlining of both solid and hollow viscera (Figs. 4, 14), and in studying lesions of the lungs.

Liver.—It is especially easy to locate the exact dimensions of the liver and this is done through the use of certain lines known to diagnosis. The midclavicular line which extends from the centre of the clavicle to the centre of Poupart's ligament, is the most valuable landmark in measuring the liver. The median line leading from the ensiform cartilage to the pubis is also employed, and the left midclavicular line (Figs. 5, 6). The extent of liver dullness by auscultatory percussion of the right midclavicular line, in normal subjects, when standing is five and a half to six and a half inches. In the median line the extent of dullness below the tip of the ensiform will be found to vary between two and a half and four inches. In the left midclavicular line the extent of dullness is conspicuous in the presence of hypertrophy involving the left hepatic lobe (Fig. 7). Liver dullness may also be located in the right midaxillary line and in the scapular line, but these points are only used in demonstrating the exact size of the liver.

A point of value in diagnosis is the establishment of the upper line of the liver dullness, together with the upper border of a pleural effusion. Auscultatory percussion discloses accurately the extent of liver dullness, and ordinary percussion will in all instances establish the upper line of a pleural effusion. The question of movable dullness should be taken into consideration in making a differential diagnosis. The line of contact between the liver and a right pleural effusion is an irregular one, the dome of the liver rising to about the fifth rib. The portion of pleura resting on the dome of the liver and extending down on the diaphragm contains a cap of fluid of varying depths, and percussion notes vary greatly over this area. By placing the stethoscope well toward the inferior margin of the liver (Fig. 6) it will be possible to detect the upper border of this organ. In making deductions from the findings given by auscultatory percussion or auscultatory palpation over this portion of the liver, one must ever keep in mind the topographical anatomy of this region. I have recently studied in my wards at the Philadelphia General Hospital two cases with pronounced distention of the gallbladder and in both instances it was possible to outline the gallbladder by auscultatory palpation (stroking of the skin). The gallbladder was palpable in both cases and while the x ray failed to show any special shadow in the gallbladder region, the clinical facts disclosed by auscultatory palpation were confirmed at autopsy.

Kidneys.—Tumor of the kidney is detectable through both auscultatory percussion and auscultatory palpation. The technic previously outlined for the liver will enable the operator to ascertain the actual size of any tumor originating from the kidney.

Tumor of the pelvic organs, especially ovarian cysts and uterine fibroids, can be localized and satisfactorily studied by these methods.

Spleen.—Place the stethoscope in the left midaxillary or the posterior axillary line, at a point between the ninth and eleventh ribs. Splenic note is always obtained at this area (Fig. 8). In event of a tumor in the left flank, it can be separated from splenic tumor by placing the stethoscope at the above mentioned point, and then starting percussion beyond any abdominal tumor and advancing toward the stethoscope. I have found it possible to separate enlargement of the spleen from enlargement of the left kidney, and other abdominal tumors. It was recently found possible to distinguish between enlargements of the spleen and a small abdominal aneurysm, in a case studied at the Philadelphia General Hospital.

Lungs.—Whenever employing stethoscopic percussion in a study of the apices one must ever be alert to the possibility of confusing notes due to the bony anatomy of this region. Any variation in force, of the percussion stroke, may also give misleading sounds.

The method suggested by Alexander gives the best results when comparing the two sides (Figs. 9, 10). A stethoscope with two diaphragms is used, and the conduction of vibrations through the operator's fingers to the upper diaphragm gives unequaled results in beginning disease of one apex. Alexander's stethoscope and his technic must be regarded as important additional steps in chest diagnosis.

Auscultatory percussion is of inestimable service in outlining cavities and areas of pulmonary consolidation, where it is impossible to move the patient. In the daily observation of cases of pneu-

monia it is the only method by which we can ascertain the actual outline of the involved lung without tiring, or annoying the patient. It is in this connection that auscultatory percussion contributes one of its greatest services.

Areas of consolidation or of partial consolidation are easily detected at the bases and central portions of the lungs. It has been found by me and by Alexander that in the study of pulmonary disease of the insane, the method of diagnosis under discussion has no peer. It is possible by stroking of the skin to detect small areas of consolidation in any portion of the lung (Fig. 11). Stroking of the skin while listening is also of service in studying patients who have pulmonary disease complicated by laryngitis. My experience is that this method is more helpful in the study of pulmonary conditions in children, adults desperately ill, and in the insane, than is any other one physical method.

Hollow abdominal viscera.—I have found after the employment of auscultatory percussion and palpation both in private and hospital routine examinations that unparalleled advantages of this method are apparent in examinations of the hollow abdominal viscera. The stomach and colon through the employment of auscultatory percussion may be sketched upon the patient's abdomen with as great a degree of accuracy as can be done by the x ray. Stewart employed auscultatory percussion to determine the location of the gastric fundus in 1897.

In determining the size of the stomach, the first essential factor is to localize definitely the pylorus, and this being done, determine next to what height gastric tympany rises in the left anterior and midaxillary lines (Fig. 12) and third, locate the inferior border of the fundus (Fig. 13). One can sketch the exact shape of the stomach on the abdominal wall. This procedure gives the clinician a life diagram which when considered with relation to the other abdominal viscera, and to the patient's general condition, completes a chain of data that holds an important place in abdominal diagnosis. The note of gastric tympany when obtained by auscultatory percussion and palpation is vastly different from colonic tympany, and from the tympany obtained over the small intestine.

Colon.—A study of the colon necessitates that the clinician be wholly cognizant of the topographical anatomy of this portion of the alimentary tract. Even more essential is it that one recognize the four fixed points or permanent attachments of the colon to the abdominal parietes.

"Of the three parts of the colon, the first or ascending passes upward from the cecum to the under surface of the right costal arch, where below the liver it bends sharply to the left to form the hepatic flexure. From this point the transverse portion, more or less in the form of a U shaped tube, loops across the umbilical region to the left costal arch beneath which it twists upward, backward, and to the left as the splenic flexure, below the spleen and behind the stomach, and at a higher level than that of the hepatic flexure. The descending portion of the colon runs down the left side of the abdomen from the splenic flexure to the iliac crest" (Figs. 14 and 15).

It is my custom to divide the abdomen into quadrants. This scheme presents many advantages, and is rapidly displacing other arbitrary divisions of the abdomen.

A study of the colon with a view to ascertaining its location and size is begun by placing the stethoscope bell over the colon at one of these socalled fixed points, and while listening make gentle percussion over another fixed point well removed from the stethoscope bell (Fig. 17).

In event of the bell resting immediately over the colon and percussion being made over another section of the organ a characteristic ringing note is audible. The next step after determining the location of the cecum is to reverse the order of technic (Fig. 18) and place the bell of the stethoscope over the distended or larger colon and begin percussion well into the right flank, advancing the width of the finger after each stroke until the characteristic colon note is heard.

The stethoscope may be allowed to remain in the same position (Fig. 18) and percussion begun to the left of the median line below the umbilicus (with each stroke, advance to the right until the border of the colon is reached, when the same colonic note is heard). It will be always noticed that while advancing in percussion from the stethoscope bell the note over the colon further from the location of the bell is distinctly increased. This method requires but little practice for its employment and will enable the examiner to outline definitely the cecum and ascending colon. Since the employment of this method, I have found that dilatation of the cecum and in fact of the entire colon is by no means uncommon. In both private and hospital cases, I have made it a rule to check the findings through x ray studies, and but slight difference in the calibre of the colon was noted.

Dilatation of the cecum has been found by me to be common in focal infection. (Nine examples shown in clinic before the members of the American Congress of Internal Medicine in April 1923, studies made with Frederick Weidman). A large percentage of these cases have shown lessening in the calibre of the cecum and ascending colon following removal of infective foci.

Estimation of the transverse diameter of the colon at any given point, after it has first been outlined by auscultatory percussion, is more closely determined by auscultatory palpation. Place the stethoscope bell over one border of the colon and by stroking the skin with a fine file, advance toward the opposite border of the colon. The note obtained when the file is drawn across the skin overlying the colon is unmistakable (Fig. 19).

A series of private cases have been studied by this method and in all of these I have had an x ray study made by M. K. Fisher, whose findings correspond well with those obtained by auscultatory percussion and auscultatory palpation. It is of interest in this connection to note that four of these cases also displayed abnormalities of the sella turcica and pituitary. Further study is necessary to determine whether a definite clinical relationship exists between pituitary disturbance and dilatation of the colon.

The Balance Between Food Intake and Insulin Dosage

LESLIE T. GAGER, M.D.,
New York
Adjunct Professor of Medicine, New York Polyclinic Medical School and Hospital

The effective use of insulin depends on two factors, one, a properly adjusted food intake, and the other, adequate control of sugar in urine and blood. It is the purpose of this paper to discuss these essential elements of diabetic treatment as they present themselves in the record of a patient whom we have had the privilege of studying in the hospital during a continuous period of five months.

CASE RECORD

Case.—E. C., sixty-six years of age, Scotch, a housewife, was admitted to the New York Polyclinic Hospital, in the surgical service of Dr. A. S. Morrow, on August 25, 1923, with diabetic gangrene of the left foot and calf. In the family diabetes was unknown. The patient had had typhoid at thirty-one, without complications. Otherwise, she had been a healthy and hardworking, temperate woman. She weighed 160 pounds, one year before admission; height, five feet one inch.

In November, 1922, a warty growth, which she pulled from a toe, was succeeded by an ulcer, which did not heal. Loss of weight set in, with thirst and frequency of urination. Not until August, 1923, when the entire foot had become involved, was the urine examined and sugar discovered. The patient refused operation at one hospital, and came to the Polyclinic Hospital on August 25th, seeking palliative treatment.

On admission, the woman was greatly emaciated, septic, and weakened; there was marked glycosuria (2.4 per cent.) and ketonuria, and the blood sugar was 0.25 per cent. Restriction of the diet and the palliative measures did not prevent extension of the gangrene and infection. The patient's consent was at length secured, and on September 7th, at 4 p. m., under gas-oxygen anesthesia, amputation at the lower third of the thigh was carried out by Dr. Morrow. The patient then came for the first time under the care of the diabetic service.

At 5 p. m., one hour after operation, twenty units of insulin were given subcutaneously. The first postoperative voiding at 9 p. m. gave heavy reduction of Benedict's solution, and strong nitroprusside and ferric chloride reactions. A voiding at 4 a. m. showed less reduction and blood at 8:30 on the morning after operation contained 0.28 per cent. sugar, with a CO_2 combining power of 39 volumes per cent. Physical examination at this time disclosed a painfully thin, even cadaverous looking, individual. The weight was evidently less than eighty pounds. There was marked pallor, the skin was dry; the peripheral arteries were moderately sclerosed, the knee jerk was sluggish. Heart, lungs and abdomen were without pathological findings; the blood pressure was 110/80.

The immediate problems were to check acidosis, and to provide the optimal physiological conditions for healing, namely, the reduction of hyperglycemia to a level within normal limits, and a protein intake sufficient to insure nitrogen balance during the process of tissue formation. The diet chosen was carbohydrates 60, protein 50, fat 60, yielding 980 calories. The protein was given on the basis of one gram to the kilogram of body weight, fifty kilograms being an estimation which allowed for the loss of the leg and a desirable degree of undernutrition. Sixty grams of carbohydrate, plus the glucose derived from protein (twenty-nine grams) and from fat (six grams) calculated after Woodyatt's formulæ, provided an amount of sugar, which if completely oxidized itself, would also insure the oxidation of the fatty acids of the diet plus those ketones responsible for the existing acidosis. This diet was given in three equal portions, and twenty units of insulin, one half hour before each meal, was the amount tentatively selected to effect oxidation of the glucose.

After forty units on September 9th, glycosuria was reduced to a faint trace. To avoid possible hypoglycemia, after the urine had become sugar free, the insulin dose was cut to forty and then to thirty units a day. On September 12th, the blood sugar was 0.14 per cent., with no glycosuria or ketonuria.

To approach a maintenance level, the calories were raised to 1,250 by making the diet carbohydrate 60, protein 50, fat 90. Sugar reappeared in the urine, along with diacetic acid, and even with forty-five units a day, blood sugar rose to 0.20 and 0.19 per cent. The wound was sloughing extensively. By reducing the diet to carbohydrate 30, protein 50, fat 90, on September 23d, and the insulin to ten units, three times a day, the blood sugar was held down to 0.16 per cent. on September 25th, and 0.13 per cent. on September 28th. During this period the wound progressed toward healing. The attempt to reduce insulin to ten units twice a day led to a temporary hyperglycemia of 0.25 per cent. A balance was struck by making the doses fifteen units before breakfast and ten units before supper, with the result that the blood sugar was 0.12 per cent. on November 1st, and the same on November 12th. By the latter date, the wound was healed, the weight was eighty-four pounds, and there was a striking improvement in the patient's color and general appearance.

Calories were now raised to 1,670, by increasing fat to 150 grams, carbohydrate remaining unchanged. In so doing, the fatty acid glucose ratio, expressed in grams, was raised from the conservative 1.5:1 to 2.1:1, but only rarely did a trace of acetone appear in the urine. On November 20th, the blood sugar was 0.11 per cent., and the patient weighed ninety pounds on November 27th.

With the change to the more powerful ("U") preparation of insulin, the doses were reduced to ten units before breakfast and eight units before supper.

A study of blood sugar variations during the day, on the schedule of two doses of insulin a day, was made on December 11th, with these results: 8 a. m. (before insulin), 0.103 per cent.; 11 a. m., 0.10 per

cent.; 3 p. m., 0.13 per cent.; 9 p. m., 0.13 per cent. For the purpose of comparison, the eighteen units of insulin were now given in a single dose before breakfast, and after a week on this schedule, this curve was obtained; 8 a. m., 0.12 per cent.; 11 a. m., 0.12 per cent.; 3 p. m., 0.13 per cent.; 9 p. m., 0.13

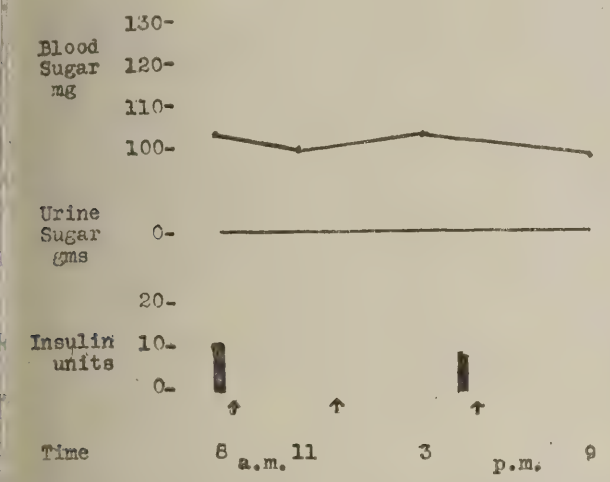

FIG. 1.—Patient E. C., December 11, 1923. Blood sugar levels with ten units of insulin before breakfast and eight units before supper. Diet, carbohydrate 30, protein 50, fat 150, given in equal portions at times marked by arrows.

per cent. The urine at no time showed sugar. The weight on December 22d was ninety-five pounds. The patient was beginning to walk on crutches.

With this favorable progress, the diet was raised first to carbohydrate 50, protein 50, fat 150, and then to carbohydrate 60, protein 50, fat 150, while insulin was reduced to fifteen, ten, and finally five units once a day. After January 10th, when the blood sugar was 0.14 per cent., the insulin was discontinued. The patient left the hospital unexpectedly on January 20, 1924, when the opportunity presented for her to enter a home. The urine remained sugar free up to discharge, and the patient wrote in September, 1924, to say that she was very well. Further blood sugar determinations are of course extremely desirable as a guide to proper dietary restrictions.

It is a pleasure to acknowledge here the cooperation of Dr. C. H. Gratz, resident physician, Miss Hilzer, dietitian, and Miss Swett, of the pathological laboratory, during this long period of study.

DISCUSSION

Experience with insulin teaches that the problem of dose is an individual one for each patient, and that in the same patient, as this case shows, this dose may change from time to time. On the average, perhaps, five units of insulin will remove ten grams of glucose from the urine, or will lower blood sugar by fifty or sixty milligrams to the 100 c. c. In the specific case, however, the effect may be somewhat greater, or much less, and especially is the lessening of the power of insulin true when infection, or coma, or both, exist. Other common factors that produce variation in insulin effect are body mass, the amount of glycogen storage, and the diet.

If a balance is to be struck, therefore, between food intake and insulin dose, it is our practice to take the dietary factor the fixed or known quantity. On the most practical, as well as theoretical, grounds, a knowledge of the food ingested and utilized, first in terms of carbohydrate, protein and fat, and thereby also in calories, and secondly in terms of glucose and fatty acid, is indispensable, 1, in determining the tolerance of the individual, and from this, his need for insulin; 2, in maintaining a safe proportion between the ketone and glucose forming elements of the diet; and 3, in preserving the nitrogen and energy balances of the body. With the diet controlled in this way, insulin may be given in such amount as to maintain a sugar free urine, and under ideal conditions, with the absence of hyperglycemia. Furthermore, the safety and economy of a plan adhering to moderate undernutrition should be realized. The instances that begin to come under observation, of patients who have received insulin treatment for months without a calculated diet plan, with sugar always present in the urine, commonly with a gain in weight and almost certainly without a gain in tolerance or a real checking of the progress of the disease, and who finally are stranded financially with their investment yielding no more interest, warrant repeated insistence on the principles of good diabetic therapy, with or without insulin.

In the effort to simplify the program of the majority of diabetics under insulin, whose injections must be given by themselves or a member of the family, we have been interested in replacing divided doses by one single daily dose. While in some clinics amounts of only a few units have been divided into three or two portions, each to be given before a meal, with the idea of providing an insulin distribution as nearly approaching normal physiological conditions as possible, we have been guided by the suggestions of Woodyatt and of Wilder regarding the single daily injection. In general, this has been given before breakfast, or in some instances before one of

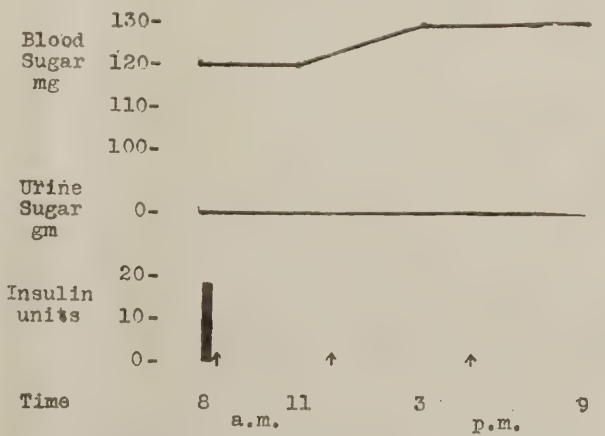

FIG. 2.—Patient E. C., December 19, 1923. Blood sugar findings after single dose of eighteen units of insulin. Diet, carbohydrate 30, protein 50, fat 150, given in three equal portions at times marked by arrows.

the other meals, to suit the convenience of the patient. Amounts from five to twenty-five units of the newer insulin have been given, without any symptoms of reaction in any case. It is interesting to note that the patient, E. C., did not have a single symptom of hypoglycemia, though naturally she was watched and questioned closely when eighteen units of insulin were being given and when the blood sugar was 0.12 per cent. The level of blood sugar in this patient is higher, by twenty to thirty mg., on the single dose

schedule, as compared with the previous week, with the same quantity divided, but the evenness of this and other curves would suggest that when too much strain is not thrown upon the pancreas by food intake, the injected insulin carries the burden of insular function for a period, after which the endogenous secretion is enabled to meet the demands of the remainder of the day. On the other hand, when the diet and insulin dose have been such that the fasting blood sugar has not been brought below 180 or 200 mg., it is not surprising that the single dose does not command the situation, for no opportunity has been given the islands to rest and regain secretory power.

If, for any reason, it is not possible to obtain a curve throughout the day, we have found in those cases in which the urine is kept constantly sugar free, that the highest level of blood sugar is usually in the evening, and that if glycemia at 9 p. m. is, say 150 mg., a satisfactory balance has been established. In one patient only (a school girl of twelve, who has gained five pounds during the last four months, and now weighs ninety-one pounds, height four feet eleven inches, on a diet of carbohydrate 60, protein 70, fat 75, and who takes twenty units daily before breakfast), has there been a feeling of warmth or flushing. This came on half an hour after the injection, that is, during the meal, on two or three different occasions, lasted about ten minutes, and was not accompanied by nervousness, trembling, or other symptoms of hypoglycemia. This girl's urine has been sugar free, except for two days during a severe cold, when her blood sugar went up to 300 mg., in place of the levels of from 175 to 150 mg., at which it is usually found. This patient is active physically, is at the head of her class in school, prepares her own diet, with the help of her mother and sister and scales, gives her own insulin, and never has a diabetic symptom.

SUMMARY

When insulin is required over an extended period, as contrasted with the emergencies of diabetes, its effective use will depend on adequate regulation of food intake on one hand and prevention of hyperglycemia on the other.

The maintenance of blood sugar within normal limits is of importance in the healing of wounds, hastening the process, or even enabling the healing to occur.

Normal glycemia is of equal importance in assisting the insular tissue, thus relieved of strain, to reach higher levels of function. Insulin permits this restoration simultaneously with a satisfactory level of nutrition.

Insulin is given with greatest safety and economy when a conservative degree of undernutrition is maintained.

In many cases, insulin may be administered to the patients in a single daily dose with the result that the amount of sugar in the urine and the blood will be controlled satisfactorily.

Treatment of Bronchial Asthma.—Leo von Gordon (*Schweizerische medizinische Wochenschrift,* April 3, 10, and 17, 1924) states that there is no fixed treatment in the sense of a specific remedy for bronchial asthma because the etiology varies in the different cases. The treatment should be adjusted to each individual case. Calcium (in the form of calcium chloride) and iodine should be tried in every case. The general treatment includes treatment of the chronic bronchial catarrh and the consideration of the secondary cardiac weakness and expiratory exercises. In isolated cases the injection of adrenalin, atropine and morphine (exceptionally in cases where there is an irritative cough) may be tried.

Foreign Bodies in the Tongue

WILLIAM H. SCHMIDT, M.D.,
Philadelphia

The possibility of a foreign body in the tongue at first thought seems an unlikely occurrence. From its situation in the mouth, and the protection afforded by the teeth and jaws, one would feel that the likelihood of a foreign body entering the tongue was rather remote. However, if we analyze the situation and consult the literature on the subject, we will find that it is far from uncommon, and several interesting facts will be brought out.

The tongue is composed of a bundle of muscle fibers covered by mucous membrane and there is little resistance to a body penetrating the tongue. Three times a day food passes over its surface, and people are in the habit of putting numerous things into the mouth at odd times such as tacks, needles, pins, and pipestems, and all that is required is an accident to supply the necessary force and the body will easily penetrate. A striking fact is that in the majority of cases reported, the foreign body is overlooked at the time of the accident and remains for some time, causing more or less pronounced symptoms, and indeed has proved fatal on more than one occasion.

Butlin and Spencer (1) call attention to the symptoms as follows:

"When the nature of an accident renders it possible that a foreign body may be embedded in the tongue, it is scarcely necessary to say that it should be carefully sought for and removed as speedily as possible. Sometimes it happens that the foreign body is not suspected, and either on account of its small size, or the depth at which it lies, there is no hardness over it, and it remains embedded and unsuspected but the wound does not heal. In a few days, the first serious symptoms may be a secondary hemorrhage, and this alone ought to excite suspicion. If hemorrhage occurs it is generally repeated, and if the body is not soon discovered and extracted, a serious termination of the case may result. In the absence of hemorrhage, inflammation may be excited by the presence of the body and a hard circumscribed indolent tumor is found through which a sinus sometimes leads down to the exciting cause. In some cases more severe inflammation is excited, suppuration occurs, sinuses form with fungous granulations protruding. Under these circumstances, the foreign body may be spontaneously discharged, especially if small, but it rarely excites such disturbance, and more commonly remains buried in the indolent inflammatory tumor which has formed around it, and cases are on record in which foreign bodies have thus remained for years."

Fork (1) relates the case of a Prussian soldier who had his teeth driven into his mouth by a bullet. On the thirty-second anniversary of the battle, swelling appeared in the tongue from which a second lower molar was removed, having remained embedded all those years.

A foreign body may be suspected if the penetrating wound does not heal readily. A careful examination of the sinus should be made with a probe. At times the wound of entrance may heal and the indolent swelling result. The history of the accident should aid and in every case should be thoroughly sought out. From the records of cases which have been reported, it would seem that sufficient attention is not paid to the possibility of a foreign body even in the case where the history suggests the possibility, and every effort should be made to exclude foreign bodies before assuming that the condition is due to some other cause. The fact that a wound of the tongue does not heal may be at times ascribed to the possibility of a tuberculous condition. In cases where the wound has healed and an indolent tumor results, the condition has been mistaken for a malignant growth and unnecessary mutilation resulted. When all efforts at manual detection in a suspected case have proved of no avail, a radiographic study should be made, as many of these foreign bodies may be revealed.

The extraction of a foreign body from the tongue should not be regarded lightly, as the history of some of the reported cases will show. Butlin advises that every case of foreign body should be removed only after due preparation for the possibility of hemorrhage. The patient should be anesthetized in a good light, mouth well open, a thread passed through the tongue and a proper assistant at hand.

In looking up the literature on the presence of a pipestem in the tongue, I was able to find five cases which I will briefly detail:

Case I.—The first case (1) was a man aged twenty years admitted to Guy's Hospital under Bransby Cooper. Three days before, he was smoking when the elbow of a companion struck the bowl of the pipe and drove the pipestem into his tongue, breaking off three inches. He fainted on account of the pain, and the surgeon found a wound passing obliquely from right to left, which he probed and struck nothing. No bleeding occurred but he sought admission for swelling of the tongue and throat which impeded speech and swallowing. On the fifth day, the swelling was less and the wound noted in the tongue had closed. On the sixth day, he vomited a pint of blood, and this vomiting recurred so that by the twelfth day he was extremely anemic. No wound could be made in the tongue from which the blood would come, but there was still considerable swelling of the tongue and fauces, and the jaws could not be opened widely so that the view was incomplete. He continued to vomit blood and died on the fifteenth day after vomiting blood and clots.

Postmorten examination.—The wound had transfixed the tongue from left to right and both openings had closed, but in the tract of the wound within the tongue was a piece of pipestem two and one half

inches long. Opposite the wound of exit on the left side was a small irregular opening just behind and below the left tonsil, from which injected material came freely when the carotid artery was injected. This was doubtless from the internal jugular vein as the clinical course of the case indicated, but there was no dissection made to clear up this point.

Case II.—A curiously similar and more startling case occurred to Hamilton (1) at the London Hospital. A man aged thirty was smoking when he fell and drove his pipestem into his tongue. The tongue began to swell, and gargles were used. On the fourth day, he was taken to the London Hospital with the tongue enormously enlarged. The dresser lanced the tongue and let out an ounce of pus. As the respirations became difficult; Hamilton was sent for and he probed the abscessed cavity and struck the pipestem, and seizing it with forceps pulled out a length of four inches. This was followed by a torrent of blood, and the patient died in less than a minute in spite of compression of first one and then both carotids.

Postmortem examination.—It was found that the pipestem had entered the right tip of the tongue, had emerged on the opposite side near the root and then passing beneath the left tonsil had gone completely through the left carotid artery and the internal jugular vein.

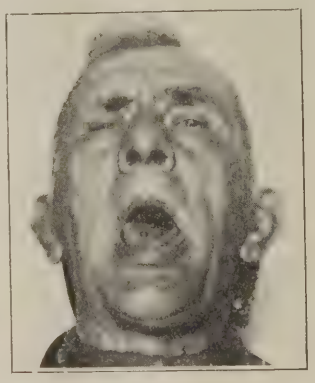

Fig. 1.—Patient with pipestem embedded in tongue. Showing stem after having been loosened and withdrawn slightly.

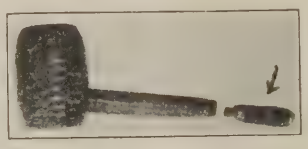

Fig. 2.—End of pipestem wrapped with string which was removed from tongue after remaining embedded for sixty-three days.

Case III.—Anderson (2) reports a case in which the amber stem of a pipe had remained embedded and unrecognized for a month in a man's tongue.

Case IV.—Murry (3) reports a case in which a pipestem remained embedded in a man's tongue for eight months. It was three quarters of an inch in length, one half inch wide and one quarter inch thick. A sinus had been present all during this time which entirely disappeared on the removal of the pipestem.

Case V.—Saffley (4) reports the case of a man aged sixty who fell with a clay pipe in his mouth. The tongue was swollen and painful when seen four days later. The patient was given mouth washes. He returned in three weeks when the sinus which had formed was incised, but nothing was found. Two weeks later, under general anesthesia, the sinus was again explored and widely opened, a pipestem one inch in length was removed after having remained thirty-five days. Healing resulted.

The case which came under my observation recently has in many respects a similar history. The patient was a man aged seventy-two who gave the following history:

Case VI.—He was returning home late one night when he fell with his pipe in his mouth. He immediately suffered great pain in the mouth and bled a great deal. The patient was so shocked that he lay on the ground for seven hours before he was able to get home. He finally got home and the next day called a doctor. The physician who saw him twenty-four hours after his injury reported that at that time the tongue was so swollen he could neither talk nor swallow, and the glands of his neck were swollen as well as the tissue as far down as the sternum. The patient suffered such great pain that he was removed to the hospital the following day, where it was necessary to feed him through a tube. This was kept up for a week, at the end of which time he could swallow a little. It was then found that his teeth had cut his tongue, and four of these were extracted and pus seemed to come from one lower molar on the left side that had been extracted. Pus was also noticed coming from the dorsum of the tongue about three quarters of an inch from the apex and to the right, and when pressure was made under the chin pus would flow also at the right side. Later, a hard surface at the right side of the tongue could be felt, but at no time was an opening seen on the right side of the tongue. A probe was used in the opening on the dorsum of the tongue but would not pass for any distance, and nothing was discovered to suggest the presence of a foreign body. On the fifth day the patient had a severe hemorrhage and brought up a puspan full of blood. This hemorrhage did not recur. Several other members of the hospital staff examined the patient, and all wondered at the extensive injury from such a slight cause. The attending physician went carefully into the history, and particularly asked if the patient had been smoking a pipe, or if he had a stick or anything in his mouth at the time of the accident.

The swelling finally disappeared somewhat but the patient suffered great pain, and after eight weeks left the hospital and came to Philadelphia where he applied for treatment at the surgical dispensary of one of our hospitals. In the meantime, a sinus had formed under the chin and was discharging pus. After examination at the dispensary, the patient was given a mouth wash and ichthyol ointment applied to the neck. He visited the dispensary daily for nine days and received no other treatment. As the pain in his mouth continued, he consulted a dentist, as he thought the pain might be coming from a tooth, which tooth the dentist extracted, and noting the condition of his tongue and mouth referred him to me for possible malignant disease of the tongue and floor of the mouth. Examination at this time showed marked infiltration of all the tissues under the chin with a sinus just above the thyroid cartilage discharging pus. Examination of the tongue showed an infiltration of the entire anterior part. There was marked salivation, difficulty in eating and talking. A small ulcerated area was present on the dorsum of the tongue about three quarters of an inch from the apex. The case had many aspects of a malignant condition with the exception that the tongue and the tissues of the neck were extremely sensitive, and that the patient suffered great pain continuously. The patient in giving the history suggested that he felt that the condition was

caused by a tooth cutting his tongue. This caused me to investigate the ulceration on the dorsum of the tongue, and on using the probe a hard body was promptly encountered. This I thought was possibly a tooth which had been knocked out and was still sticking in the tongue. I then took hold of the hard body with a pair of forceps and with some difficulty was able to remove it. It proved to be the end of a pipestem from an oldfashioned corncob pipe. The stem was well wrapped with string and the pipesteam measured one and one half inches long, one half inch wide, and three eighths of an inch thick. It had remained in the tongue for a period of sixty-three days. The removal was followed by a discharge of pus, but there was no bleeding. The sinus in the tongue and under the chin healed, and the infiltration in the tongue and neck disappeared. The patient expressed great relief from pain immediately after the removal of the foreign body.

From the history of this case, and the other cases which have been briefly outlined from literature, it would seem that the physician should be on guard for the possibility of a foreign body in penetrating wounds of the tongue. In every case which has been referred to, including the present one, the foreign body was overlooked at the time of the accident and not discovered until some time later. Two of the cases proved fatal, so that the condition is a serious one, and from past experience, the removal of a foreign body of this character from the tongue should not be undertaken unless precautions are taken for possible hemorrhage. Again, the presence of a sinus discharging pus following an injury of this kind strongly suggests the presence of a foreign body. Several of these cases were carefully examined with a probe and yet the foreign body was missed. An x ray examination of these cases would probably be of great help as there is slight density to the tongue, and many of these objects, such as pipestems or metallic substances, would certainly cast some shadow, and thus aid in the diagnosis.

In conclusion, I felt that the case was interesting enough in itself to be reported, but the investigation of the literature on the subject has brought out the fact that foreign bodies in the tongue are not at all uncommon and that they are frequently under discussion; that they always cause more or less severe symptoms, and in some cases they have proved fatal.

Pellagra*

NEWDIGATE M. OWENSBY, M.D.,
Atlanta, Ga.

In reviewing the literature on pellagra which has appeared in the past several years, the most striking observation noted is the wide divergence of opinion regarding its etiology. Some authors are convinced that it is the direct result of the consumption of diseased maize, while others are equally as positive in their belief that it is due to the presence of colloidal silica in the drinking water, parasites, microorganisms, poor sanitation, dietetic deficiencies, etc. Each writer has presented his particular hypothesis in a most satisfactory manner and one is almost persuaded that the last theory advanced is the correct solution to the etiological problem until he reads another which is correspondingly convincing. Therefore, before accepting any hypothesis as conclusive, it would be well to analyze each one and eliminate those which cannot be proved by clinical or laboratory methods.

The Austrian and Italian governments took sufficient cognizance of the diseased maize theory to institute prophylactic measures which would prevent the milling and consequent consumption of affected maize by the inhabitants of their respective countries. The reports following the inauguration of these measures were sufficiently gratifying to inhibit other research into the etiology of pellagra until it was ascertained that the disease was prevalent in communities where maize did not form a part of the diet. Because of this discovery the maize theory was subsequently discarded and another substituted to the effect that the bite of the Buffalo gnat was the causative factor. Upon further investigation it was learned that this gnat did not inhabit countries wherein pellagra was endemic; therefore, this hypothesis met the fate of its predecessors and shortly thereafter it was announced that the presence of colloidal silica in the drinking water was the true cause of the disease. The soil of all pellagrous districts was then analyzed by chemists and when the reports were collected it was noted that pellagra occurred in regions where the soil and water were free from contamination by silica and that in those regions where silica was present, only a small percentage of the inhabitants were afflicted with this disease. Hence another theory had to be abandoned.

The theory that pellagra was due to the microorganism or parasite and was communicable gained considerable momentum when Harris laid claim to having transmitted the disease to a monkey. Since neither Harris nor any other investigator has been able to reproduce this experiment, it is reasonable to suppose that other factors which he failed to observe were responsible in this particular case. Moreover, it has been frequently commented upon that pellagra never occurs in prison guards, attendants or nurses connected with institutions where the

*Read before the Chattahoochee Valley Medical Association, July , 1924.

disease appears to be almost epidemic. This theory continues to have many adherents despite the fact that the evidence against its tenability seems overwhelming.

The circumstance that pellagra appears in districts where the sanitary conditions are superior to those districts where the disease is unknown, and also that pellagra continues to occur in districts where the sanitary conditions have been improved, would seem to eliminate the sanitary question as a possible factor in the production of pellagra.

To those who have had the opportunity of making close observations of pellagra, the theory advanced by Funk and the more recent experiments in dietetics carried out by Goldberger and his associates, appear to be the most nearly correct solution of the etiological problem thus far advanced.

In 1912 Funk called attention to the close analogy of the symptomatology of beriberi and pellagra, and stated that it was his belief that pellagra was due to a deficiency of vitamines in the food of those individuals so affected. Of this Goldberger has to say, "while much may be said in favor of this attractive theory, it still lacks demonstrative proof." In summarizing the results of his dietetic experiments, however, Goldberger states that the "exact dietary factor or factors constituting the specific pellagra producing fault is undetermined, but it is to be sought in some combination or combinations of the following: a, a physiologically defective protein (aminoacid) supply; b, a defective or inadequate mineral supply, and c, a deficiency in a yet unknown dietary essential (vitamine)," thereby acknowledging the possibility of the correctness of the theory advocated by Funk. In more recent articles Goldberger looks with greater favor upon a defective aminoacid supply.

In order to have a clearer conception of the theories advanced by Funk and Goldberger, it is necessary to examine into some of the more conspicuous facts associated with the occurrence of pellagra and note the apparent bearing they have on the etiological problem.

It has been stated that pellagra is a poor man's disease because of its predominance among the indigent members of society. The majority of cases which have been observed in this country are seen among the poor in the mill villages, institutions, and rural sections of the South, while the same peoples in the North, East and West have enjoyed comparative freedom from this malady.

The sectional difference in the appearance of pellagra is often explained by the fact that physicians residing in nonpellagrous districts are unfamiliar with the disease and fail to recognize the cases they come in contact with. This explanation is probably true in occasional cases, but cannot be accepted as the true explanation for the enormous disproportion of cases, therefore, it would be well to consider other factors.

The sanitary conditions of the institutions, mill villages, and rural sections of the south are not inferior to those of other sections and certainly not as bad as those existing in the larger cities of the east, north and middle west. The composition of the soil in the different geographical areas does not show any appreciable difference. The climatic conditions in the pellagrous districts is not unlike that of sections where the disease is unknown. Moreover, pellagra is rarely observed in the tropical, semitropical, and temperate zones of the countries to the south of the United States. The economic, occupational and environmental conditions appear to be very much the same in all sections, whether pellagrous or nonpellagrous. All other conditions, with the exception of diet and its preparation, are about the same in each section of the country.

Because of the large number of dairy and truck farms in the north, east and west, the poorer members of society in these sections have found that milk, fruits and vegetables, particularly when in danger of becoming overripe, are the cheapest foodstuffs to be procured and their diet has consisted largely of these articles of food. Despite the better climatic conditions in the south dairying and truck farming have not been followed to any extent until within very recent years and the poor people of this section have limited their diet to molasses, corn bread and salt pork. The cost of fuel in the north, east and west has influenced the inhabitants to cook their food for the shortest possible time, but in the south it is an almost universal custom to cook vegetables for several hours.

Therefore, it may be stated that the dietary of the poorer classes in the nonpellagrous districts is rich in water soluble vitamines which are not extracted by cooking and that the dietary of the same classes in the pellagrous districts are either devoid of the water soluble vitamines or else they are extracted in its preparation for consumption.

The dietary of the better classes in the pellagrous districts contains larger amounts of water soluble vitamines and therefore they are seldom afflicted with this malady, except in those persons who have a pronounced psychic aversion to vitamine containing foods.

It has been noted that the acute exacerbations of pellagra are most often observed in the spring or early summer months, which is most suggestive, since vitamine containing foods are harder to procure in the winter months. Then, too, the provender of cows is short of vitamines except in the dairying districts where silos are used, and this has a tendency to impoverish their milk. The fact that truck and dairy farming has increased, that the economic conditions have improved, and that a noticeable subsidence of pellagra in the south has occurred within the past few years, may be considered significant.

Other significant observations favoring the theory that pellagra is due to lack of water soluble vitamines which may be cited are, a, the comparative freedom from pellagra of the members of the Jewish faith, whose religion insists upon kosher food, which is vitamine containing; b, the absence of pellagra in European countries during the war when many subsisted on raw vegetables and were unable to procure meats or other foods rich in proteins; c, the slight predominance of the disease in females whose habits are not as roving as those of the male, whose occasional visits away from home give him an opportunity to partake of fruits or vegetables, and d, the fact that a marked diminution of the disease appeared in those institutions where Goldberger and the Thomson-McFadden Commission had vegetables added to the dietary.

I have had occasion to observe twenty-eight cases of pellagra within the past five years, in which the only treatment consisted of the addition of tomato juice, raw cabbage, lettuce, and the water in which vegetables had been cooked (colloquially known as "pot liquor"), to their daily diet and a recovery was recorded in each case. The time required for a complete abatement of all symptoms varied from three to sixteen weeks, depending upon the advance of the disease. The slowest to recover presented a rather well marked psychomotor retardation, slight amnesia, and complained of intense headaches in addition to the more familiar symptoms of the disease. It was noted that each patient had previously subsisted on a vitamine free diet and had a marked aversion to the foods prescribed. Dr. W. H. Hailey, of this city, has had occasion to treat three acute cases by this method within the past year and reports that each patient recovered within three weeks.

The symptomatology of pellagra and its close analogy to beriberi, polyneuritis, and other similar conditions, show it to be primarily one of the neuritides and the subsequent mental symptoms are secondary to the involvement of the peripheral nervous system. There have been many types or clinical forms of nervous and mental disturbances accredited to pellagra, by various writers, wherein certain clinical symptoms predominated and this has led to a confusion of the symptomatology of the disease and caused many erroneous diagnoses. It should be borne in mind that pellagra, like many other diseases, may be associated with any neurosis, psychoneurosis or psychosis without having any specific relation to them. The true pellagrous psychosis has many psychic symptoms in common with those presented in Korsakoff's psychosis. Those cases which have been described as presenting symptoms of dementia precox, manic depressive psychoses, anxiety psychoses, etc., are probably coincidental and have no direct connection with pellagra.

The pathology of pellagra has never been definitely worked out, but there is reason to believe that in the well advanced cases the lesions are by no means confined to the peripheral nerves and that there is a general involvement of the entire central nervous system.

In view of these observations, it would appear that Funk was correct in his theory that pellagra is due to a deficiency of vitamines in the foods of those so affected. And since there is a complete subsidence of all symptoms of the disease when the patient is placed upon a diet rich in water soluble vitamines it would seem that the particular dietary factors constituting the specific pellagra producing fault is an inadequate supply of the antineuritic vitamine B, with the lack of the antiscorbutic vitamine C playing a contributory rôle.

Carbon Monoxide and Dioxide

ERNEST M. VAUGHAN, M.D.

Brooklyn

Carbon monoxide is a colorless, tasteless and practically odorless, nonirritating gas which is generated when insufficient oxygen is present during combustion to convert all of the carbon into carbon dioxide. Carbon monoxide is always present in illuminating gas.

"The proportion of carbon monoxide (1) differs greatly in domestic and industrial gases, varying between four and thirty per cent; in coal gas four to ten per cent, and thirty per cent in water gas, and twenty to thirty per cent in producer gas. Lime kiln gases, waste gases from ammonia soda processes, and gases left in the track of explosions in coal pits contain from 1.25 to 2.5 per cent. (2). Wood gas made by the Wilkinson process was found to contain 3.75 per cent., while the commercial gas served to the consumer and made by mixing gases from wood, coal and naphtha, contain 11.25 per cent. (3). Almost all illuminating gas contains a large proportion of water gas, so that when this gas is discharged into an inhabited space it becomes exceedingly dangerous. An atmosphere containing two tenths per cent is capable of destroying life (4)."

In burning buildings, poorly ventilated garages, and in similar situations, the concentration of the gas may be from one part in one hundred up to a fairly high percentage, and when present will overcome a human being, and in high concentration, sometimes with a single breath. Its immediate effect is loss of muscular power and later unconsciousness.

Carbon dioxide is a colorless, suffocating, acidulous gas and occurs wherever there is combustion. When in high concentration, it causes spasm of the glottis, insensibility and death from suffocation. In low concentration, dizziness, somnolence and loss of muscular power.

These two gases, carbon monoxide and dioxide, are always present where rapid combustion is taking place, as in burning buildings, and in garages where motors are allowed to run. It is the presence of

these gases in concentrated form that accounts for the fact that able bodied, athletic young persons are unable to escape, even when a point of exit is readily accessible, as illustrated in the following.

At a recent fire in Brooklyn, when a building occupied by three families, consisting of sixteen persons, was burned, six of the occupants were found dead. One was a young man, nineteen years of age, whose unburned body was found near an unlocked, closed window, which gave access to a point of safety.

In another instance of a fire, the unburned body of a man, his lips covered with soot, was found in a toilet, a distance of twenty-five feet from the actual blaze. This toilet room contained a window which led to safety. The man had a contusion over the nose and forehead, but at autopsy these injuries were found to be trivial. Examination of the blood in both cases showed carbon monoxide to be present.

The following serves to illustrate not only the muscular weakness, but also how the trained mind failed to act in an atmosphere containing carbon monoxide in excess.

Dr. M. E. Marten, assistant medical examiner in Brooklyn, and the writer were called to a bungalow in Sheepshead Bay one extremely cold day three years ago, and found four persons dead. The house consisted of a flimsy, four room, one story structure, with all the windows hermetically sealed to keep out the cold. The living room was heated by a gas heater of the radiant type. There was no gas escaping and the heater was still burning when the tradesman called in the morning to get the orders for the day. The occupants of the home were a woman, who had been delivered of a baby the day before, the new born babe, a four year old girl, and the trained nurse. The baby was found in its basket on a table in the living room. The mother and her four year old daughter were found in bed. The nurse had left her bed and gone to the mother's room and there collapsed. She was found in a kneeling position with the upper part of her body lying face down on the bed. Had her mind functioned properly and her power of locomotion remained, she doubtless would have opened a window and saved them all. Analyses of the blood, by Marten, showed carbon monoxide to be present.

To illustrate the paralyzing effect of carbon monoxide on the muscles, and as evidence that it precedes the unconsciousness, the following case was related to the writer by the late Charles Wuest, senior medical examiner of Kings County, Brooklyn.

A pedestrian, while walking along Bushwick Avenue, Brooklyn, one cold day in February, many years ago, noticed a coach passing, the windows of which were covered with steam, and a face with staring eyes, pressed against one of the windows. He called to the coachman to see what was the matter with his fares. The driver got down from the box, opened the door, and tried to arouse his four passengers, who were all sprawled out in their seats, but was unsuccessful. He then drove to Dr. Wuest's office, which was around the corner. Wuest in turn tried to arouse by calling and shaking, but as they did not respond, the doctor, aided by the coachman, lifted them out of the coach, placed them on the sidewalk, and in a short time was able to revive them. The doctor then questioned as to their sensations and how it happened. They all agreed they had heard both the doctor and the coachman call but had been unable to move because their muscles failed to respond. They stated that on the way to the cemetery they had had a window of the coach open, but on returning, as they were cold, all the windows of the coach had been kept closed and a charcoal foot warmer used to supply heat.

As the victims in this case were able to describe their sensations, the instance bears out the present knowledge as to the paralyzing effects of the carbon oxides on the muscles, and to my mind, proves conclusively that paralysis precedes unconsciousness. The cited cases readily explain why we find young adults unable to escape from fires, though near points of exit.

This article is written so that the medical witness may, when giving his opinion, explain the cause of death in these types of accidents and account for the injuries found; as due to falling from sudden paralysis of the muscles, rather than infer them to be of homicidal nature.

The following tests for the detection of carbon monoxide in the blood, as given by Hawk (5), have been found to be practical, and the most delicate, by William W. Hala, chief pathologist of the Kings County Laboratories.

Tannin test for the detection of carbon monoxide hemoglobin: Divide the blood to be tested into two portions, and dilute each with four volumes of distilled water. Place the diluted blood mixtures in two small flasks or large test tubes and add twenty drops of ten per cent solution of potassium ferricyanide. First, allow both solutions to stand for a few minutes, then stopper the vessels and shake one vigorously for ten to fifteen minutes, occasionally removing the stopper to permit air to enter the vessel. Second, add five to ten drops of ammonium sulphide (yellow) and ten c. c. of a ten per cent. solution of tannin to each flask.

The contents of the shaken flask will soon exhibit the formation of a dirty olive green precipitate whereas the flask which was not shaken and which therefore, still contains carbon monoxide hemoglobin, will exhibit a bright red precipitate, characteristic of carbon monoxide hemoglobin.

This test is more delicate than the spectroscopic test and serves to detect the presence of as low a content as five per cent. of carbon monoxide hemoglobin.

1. This transforms the oxyhemoglobin into methemoglobin.

2. This is done to free the blood from carbon monoxide hemoglobin.

44 Court Street.

Report of a Case of Pertussis Complicating a Gastric Ulcer*

JOSEPH C. REGAN, M.D.,
Brooklyn, N. Y.

The occurrence of whooping cough in a patient with a gastric ulcer is an altogether rare occurrence, as far as one may judge from the apparent lack of any reference to it in the medical literature of the disease. The following case report is not made for that reason only, however, but also to call attention to the effect that alkali therapy seemed to have had in aborting the disease.

Case.—A woman, twenty-three years of age, was admitted to the Kingston Avenue Hospital on July 19, 1922, with a diagnosis of whooping cough. Her family history was irrelevant. She had had a severe attack of scarlatina when a child with complications of otitis media, cervical adenitis and nephritis. Later, at the age of seven and eleven years she had had two separate and distinct attacks of whooping cough, likewise pneumonia twice, at the age of nine and sixteen years. There was also a vague history of several mild attacks of rheumatic pains. At several times since the complicating nephritis during scarlet fever, she had been troubled with edema of the face, hands, and feet and with visual disturbances. Since she was five years of age the patient had suffered at intervals from epigastric pain, especially after eating, with vomiting of all but the most simple foods, such as bread and milk, and occasionally the vomitus would be streaked with blood. Her present illness began at the end of May, 1922, with the return of marked epigastric pain after eating and incessant vomiting, with hematemesis. This was followed by the development of edema of the feet and marked constipation.

The patient was admitted to the Jamaica Hospital on June 30th, and a diagnosis of gastric ulcer and chronic nephritis was made. While under treatment at that institution a coryza and cough developed in the early part of July followed about July 15th by a paroxysmal cough of a severe type with whooping and vomiting, congestion of the face and the terminal expectoration of a very tenacious mucus. With each coughing spell, the epigastric pain became indescribably severe.

A physical examination of the patient on her admission to the hospital showed her to be fairly well developed and nourished. She appeared acutely ill and depressed, complaining of weakness, epigastric pain, paroxysmal cough with whooping and vomiting. The respirations were rapid, she was slightly dyspneic, cheeks flushed; the temperature was 99.4°, the pulse 80, and the respiration 34. At frequent intervals, averaging every half hour, there were severe paroxysms of coughing lasting about sixty seconds, accompanied by the vomiting of blood stained vomitus and the expectoration of thick tenacious mucus. During the paroxysms the patient presented a most distressing sight with her hands pressed tightly against her abdomen, and beads of perspiration standing out on her face which would become quite cyanotic. After the paroxysm she would throw herself back again into a recumbent position as she felt another paroxysm supervene.

General physical examination of the chest was negative, but the abdomen showed a small area of acute tenderness about the size of a fifty cent piece in the epigastric region just to the right of the median line, near the costal margin. The urinary examination showed a moderate trace of albumin, acid, specific gravity 1004, a moderate number of epithelial and pus cells, and a few red blood cells. A blood count was reported as total red cells 3,020,000; total white cells, 11,000; polymorphonuclears, 63 per cent.; small lymphocytes, 30 per cent.; large lymphocytes, 7 per cent.; eosinophiles, one per cent.; hemoglobin, 80 per cent.

CLINICAL COURSE AND PROGRESS

On July 21st the patient was placed on Sippy's dietary treatment for gastric ulcer, hourly feedings of milk and cream. She was also given a mixture consisting of antipyrine gr. five, sodium bromide gr. five and tincture of belladonna min. five every six hours. Leucocyte extract, three c. c., and mixed pertussis vaccine min. ten were given subcutaneously on July 22d and the same dose on July 25th. An abdominal binder was applied and careful records kept of intake and output of fluids. A record of the paroxysms was kept by the patient who was provided with a paper and pencil for the purpose.

There was no improvement from the time of admission until July 26th, the number of paroxysms ranging between forty and forty-four in twenty-four hours, and increasing in severity. On July 25th the treatment was changed as the vomiting was very marked. Cream was omitted from the diet and whey and albumen water were substituted with a little lime water and cracked ice at intervals. Aklaline powders as follows were given: Powder No. 1 consisting of magnesium oxide gr. ten and sodium bicarbonate gr. ten in one powder, alternating with powder No. 2, consisting of calcium carbonate gr. ten and sodium bicarbonate gr. twenty given every other hour from 7 a. m. to 9 p. m. On July 27th all the depressants ordered, including antipyrine, belladonna, and sodium bromide, were discontinued. The vomiting continued, but only one paroxysm occurred. Powders were given now every two hours, alternately. On July 28th, the paroxysms stopped. Vomiting had diminished, and the powders were given alternately every four hours. On July 30th the powders were discontinued. There were no further paroxysms, but the vomiting continued. On August 1st, the paroxysms returned, but were not as frequent or as severe as previously. The alkaline powders were started again, alternately every two hours. On August 3rd, seventeen paroxysms occurred between 3 p. m. on August 2nd and 3 p. m. on August 3rd, and on August 5th the paroxysms had disappeared again. On August 12th it was reported that there had been no paroxysms since August 4th, and no vomiting since August 6th. The patient looked well

*From the Kingston Avenue Hospital of the Bureau of Hospitals, Department of Health, New York City.

and was comfortable, and had been up and around for a week. The epigastric pain after eating had virtually disappeared, but there was still a point of slight tenderness in the same localization.

The patient was seen subsequently, about the middle of October, and stated that the cough had never returned but vomiting and epigastric pain had reappeared. She was referred to the general hospital again for treatment of the gastric ulcer.

The remarkable cessation of the severe paroxysms from forty-four to none in three days of alkaline treatment was striking. Likewise the return of the paroxysms after the powders had been discontinued for three days and their final disappearance for the second time after resuming alkaline therapy are facts which seem to suggest a new line of thought in the therapy of pertussis.

SUMMARY

The development of pertussis of a malignant type in an adult patient with a gastric ulcer is a rare occurrence. I could find no previous instances recorded in the literature. The remarkable effect of alkali therapy in shortening the course of the disease offers possibly a new line of thought in the pathogenesis and therapy of pertussis.

The Significance of Enlarged Glands in the Neck

JOSEPH FRIEDMAN, M.D.,
SAMUEL D. GREENFIELD, M.D.,
Brooklyn, N. Y.

The cervical lymph nodes share in many of the local inflammations about the neck and head. They are also brought into sympathetic enlargement in general systemic affections involving the lymphatic tissue in other parts of the human economy. In many instances the etiological factor for their involvement is apparent and easily explained, while in others it is more obscure and difficult to determine. Enlargement of the cervical lymph glands is of frequent occurrence, especially in children, yet it seems to have received little attention.

The etiology for cervical enlargement may be regarded in general as falling into the following three classes: 1. Inflammations: a. Simple, following infection of the tissues about the head and neck, thus being secondarily implicated. This variety may be acute or chronic. b. Tuberculous. 2. Those enlargements occurring in connection with general affections. These may be divided into: a. The involvement of the lymph nodes in the acute infectious diseases, e. g., scarlet fever, measles, German measles, diphtheria, etc. b. Those conditions in which there is an affection of the general lymphatic system, e. g., syphilis, leucemia and Hodgkin's disease. 3. Neoplasms: a. Primary, such as lymphosarcoma. b. Carcinoma as a secondary process.

The most common forms of enlargement of the cervical glands are the acute local, infectious processes, the enlargements being secondary to bacterial invasion of structures of the head and neck and particularly of the nose and throat, the lymphatics of which terminate in one or another of the groups of lymph nodes. The etiology of primary involvement of the superficial glands is as a rule easily discernible. Knowing the area drained by a particular set of lymph nodes careful search will disclose the original seat of trouble. On the other hand this is oftentimes a difficult matter, for the stage when the more superficial glands are involved is easily overlooked. Knowing that the deeper glands which present the more conspicuous enlargement receive lymphatic vessels from a number of sources the original focus of infection is not so apparent.

The etiology of enlargement of the superficial glands may be outlined as follows: Lupus, eczema, pediculosis, furunculosis, arising in the posterior part of the scalp will cause enlargement of the occipital group. The same conditions about the ear, and particularly an external otitis either circumscribed or diffuse, will produce enlargement of the posterior or preauricular nodes. Sores about the alæ nasi, fissures and cracks about the nostrils and corners of the mouth, and infections of the tongue surfaces, especially in the various forms of stomatitis, will produce enlargement of the submaxillary and facial glands. Similar conditions about the chin and lower lip will affect the submental glands. Pyogenic infection of the gums and periosteum produces enlargement of the submaxillary group. Carious teeth *per se* do not affect the lymph nodes. It is only when the gums become eroded or the bones about the roots are infected that lymphatic involvement is noted (1).

For enlargement of the retropharyngeal glands we look to infections of the nose and throat and particular stress should be laid upon the adenoid tissue in the vault. The superior deep cervicals are invariably affected simultaneously, the involvement of these glands oftentimes giving us a clue to the existence of a swelling on the postpharyngeal wall. We recently reported a series of sixty cases of retropharyngeal abscess (2) in which practically all the cases showed original trouble in the nasopharynx. Pinches (3) found that a purulent rhinitis preceded fifty per cent. of all cases of retropharyngeal abscess.

In those patients who present enlargement of the superficial cervical glands without any gross pathological focus we should always suspect pediculosis capitis. This is one of the common causes for such lymphatic involvement in both children and adults. Even in the best of families where children receive the utmost care this condition prevails (4).

It can readily be seen that the affections causing enlargement of the superficial cervical glands are not of a very serious nature; they are transient and usually amenable to treatment. However, it is a different matter with the deeper glands. Their in-

volvement ordinarily signifies a more severe infection; they persist over a longer period of time and are often accompanied by some systemic disturbances. According to Wood (5) the importance of the nose, throat and mouth as the starting points for cervical adenitis is paramount and he regards this as being the source in ninety per cent. of cases. From our experience we feel this is not an overestimated figure. Likewise according to Müller (6) the structure of first importance is the faucial tonsil, next the pharyngeal tonsil and other lymphatic structures of the pharynx, including the lingual tonsil, then the gums and alveolar processes and lastly the nasal cavities and accessory nasal sinuses. Gardiner (7) places the responsibility for cervical adenopathy on the faucial tonsils at eighty per cent. of chronic cases. Sutcliffe (8) attributes the great frequency of cervical adenitis in children to the coincident tonsil infections which are so prone to occur in childhood. There is no question that the tonsil is the great portal of entrance in the acute as well as in the chronic adenopathies. The opinion is certainly a scientific one and is based upon experimental facts and clinical evidence. The faucial tonsil is of prime importance chiefly because of its size and depth of its crypts. Furthermore, the tonsil is exposed to a continuous contamination from a rich flora of bacteria ever present in the oral cavity. The histological arrangement in the tonsillar crypts is such that little defense is afforded to invading microorganisms. The peculiar disintegeration of the basal cells and their lack of cohesiveness makes necessary only a slight abrasion of the superficial cells before the parenchyma of the tonsil itself is open to invasion.

Considering the acute adenopathies resulting from nose and throat infections we must recognize the fact that in all these cases there are present some evidences of the original affection. These patients are taken sick with an acute follicular tonsillitis, or an acute rhinitis, or an acute rhinopharyngitis. A day or two later there appears an enlargement of one or more of the cervical glands, usually the superior deep cervicals located beneath the sternomastoid muscle. Typical in cases where the faucial tonsil itself is affected we note an enlargement of at least one particular node located at the junction of the anterior border of the sternomastoid and posterior belly of the digastric. This mode was first described by Wood and designated by him as the tonsillar node. It receives directly the lymphatic drainage from the faucial tonsil.

These deep cervicals vary in their enlargement. As a rule they are moderately enlarged so that they are easily palpable. A characteristic feature very often in these acute cases is the tenderness elicited upon palpation. Their enlargement contributes partly to the hyperpyrexia. They seldom suppurate under these conditions although in children such an unfortunate event is not rarely seen. The enlargement does not persist over a long period and resolution is practically commensurate with subsidence of the original inflammation of the nose and throat. However, the cervical enlargement may persist for some period after the patient has recovered from his tonsillitis.

The involvement of one or two glands, followed by resolution after a short time, represents the usual case and the usual sequence. However, there is one type of case acute in nature in which there seems to be a more general involvement of the glands; in which the condition persists over a longer period; where the glandular affection overshadows the original nose and throat infection. We here refer to the socalled more or less obsolete term glandular fever, first described by Pfeiffer in 1889. We cannot share his opinion that the condition is an infectious and specific disease occurring as a distinct entity. The fact that it is seen in epidemics is no added proof, for those holding the opinion that the glandular enlargement is purely the result of a preceding local throat inflammation point out that the latter as a forerunner is responsible for the epidemics reported by so many observers. Pfeiffer himself admits that in many cases there is present some evidences in the nasobuccopharyngeal mucous membrane of previous infection. And then in the light of the more recent clinical and experimental data organisms may gain entrance through the surface epithelium with little change in the latter structure. Manning (9) reported a series of thirty such cases of acute cervical adenitis and found that all of them occurred during the early fall when acute respiratory disturbances are prone to occur. All of them had previous acute infections of one form or another of the pharynx.

This condition is most often seen in children although adults are not exempt, as has been shown by the reports of Schaffer, Botschowsky, Korsakoff and others. After several days during which there are evidences of some nose or throat infection, such as catarrhal or follicular tonsillitis, or cough or sneezing or nasal discharge, there is noted increasing pyrexia and enlargement of the deep cervical glands located beneath the sternomastoid muscle. The glands are discrete. The skin is not reddened and the tissues are not edematous. Commonly the cervical enlargement is unilateral at the outset. The glands as a rule are not tender and there is absence of pain. The patient is restless; there is anorexia, furred tongue, and the pulse is rapid. In children especially the systemic disturbances are more profound. The condition persists usually from one to two weeks after which there is a gradual drop in the temperature as well as a diminution in size of the glands. The latter, however, may remain palpable for weeks after the temperature has reached normal (10).

We have so far discussed the nonsuppurative variety of cervical enlargement and there now remains for consideration the acute suppurative form of cervical lymphadenitis. This type requires very little comment for the condition is a fairly common one and usually recognized. Its occurrence is most often seen in young children, under two years of age. The infection originates in the nose and throat. There are symptoms of the original inflammation such as rhinitis, nasopharyngitis, or tonsillitis. There is present pyrexia of a fluctuating character, the children are restless and the glands rapidly enlarge —very often making enormous swellings in the neck. There is redness of the skin, tenderness of the enlarged nodes, and the evidences of breaking down are apparent very early. Softening and fluctuation

are noted in about two weeks. The difficulty is to determine during the first few days, in which cases the glands are going to break down, and in which they are going to resolve. At the very onset this cannot be done with certainty. If the fever persists and is high, if the glands reach a large size early, then there is likely to be suppuration.

The question of chronic enlargement of the cervical glands is a rather large one. It will therefore necessitate our touching only upon the more important features of this subject. To begin with the chronic enlargement may be simple or tuberculous or it may be a combination of both, the latter being superimposed upon the former (11). Most observers are agreed that in both instances the original source of infection is to be looked for in the tonsils and especially is this true in those cases where no other gross pathological lesion can be demonstrated elsewhere in the nose and throat. The size of the tonsil makes no difference as to its infectivity except that the small submerged fibrotic type is apt to be more dangerous. That enucleation of the tonsil in such cases will cause subsidence of the glandular enlargement is a well established clinical fact and can readily be understood when we recall that the superior deep cervical glands drain the tonsil directly. Pathological examination by Willis (12) of two hundred and thirteen tonsils revealed cryptic concretions in one hundred and fifty-four; socalled abscesses in thirty, and pericryptal inflammation in one hundred and sixty-five. Waugh (13) considers chronic gland enlargement in children as due to tonsillar infection. He reports one hundred and thirty-five cases in which radical removal of the faucial and pharyngeal tonsils was rewarded with complete recovery.

We now come to those cases of cervical adenitis in which the tubercle bacillus plays an important rôle. Recently much experimental, clinical, and pathological data have been collected so that we now have definite and authentic matter upon which to base our opinions. Woods found that after inoculation of the tonsil surface in hogs, with a bouillon culture of tubercle bacilli, the organism was regained from the regionary lymph nodes before any pathological lesion could be detected in the tonsil. Willis reports after a careful macroscopical and microscopical examination of two hundred and thirteen tonsils removed from one hundred and eight patients, five per cent. showed distinct evidence of tuberculosis. Tybus believes that the tonsils when chronically diseased are tuberculous in many instances and he calls attention to the fact that the small submerged tonsil is the type apt to harbor tubercle bacilli. The susceptibility of the tonsil to tuberculosis is further substantiated by the pathological findings in human tonsils. In a series of one thousand and seven hundred and fifty-nine cases reported by twenty-six different observers tuberculosis was found in about five per cent. Mitchell (14) found that of the tuberculous species eighty-eight per cent. were infected by the bovine bacillus and twelve per cent. by the human bacillus.

It is therefore agreed that the cervical enlargement may be caused purely by the ordinary infectious organisms or it may be the result of infection by the tubercle bacillus. This therefore brings us to a consideration of the differential diagnosis of chronic simple and chronic tuberculous adenitis. This is very often a simple matter and at other times a more difficult one. The points that may help us to arrive at a conclusion in the doubtful cases may be briefly put down as follows: 1. A cervical adenitis in a child under two years is likely to be simple rather than tuberculous. Over two the reverse is more apt to be true. 2. The family history is of the greatest importance when we know that members of the family are tuberculous subjects. 3. The onset in the pyogenic type is sudden and rapid whereas in tuberculosis it is likely to be slow. However, in tuberculous adenitis in early infancy there is a picture described greatly resembling that of the acute pyogenic type, e. g., rapid enlargement, fever, tenderness, edema and matting together (15). When the condition persists over three months the enlargement is presumptively tuberculous. It may not be so however. 5. The location of the nodes may be the same in both cases. A single slowly enlarging gland, particularly if it be the tonsillar node, is in favor of tuberculosis. 6. In the pyogenic variety the swelling is larger, comprises more lymph nodes, has more perinodular infiltration, is tender, reddened and all the tissues are bound up in the swelling. In the early stages of tuberculosis these features are all lacking, but in the later stages there are just as many glands involved and they may be matted together and adherent to the skin but redness, tenderness and heat are rarely present. 7. The Von Pirquet reaction may also be an aid and especially if it is positive in children under five years of age. Then finally it may be concluded that the only final and positive method of making the diagnosis is by biopsy.

Many of the acute infectious diseases are accompanied by enlargement of the cervical glands. The involvement is essentially acute; the glands are only mildly involved as a rule and there are associated the signs and symptoms of the primary diseases. The diagnosis is therefore not a very difficult matter. In scarlet fever the deep cervicals are enlarged and may progress to intense infiltration and may even suppurate. The enlargement in diphtheria is also acute. Glandular involvement is often a notable feature in this disease. With the appearance of a membrane in the nose or throat the diagnosis is reasonably certain. In measles the eruption and the other attending symptoms serve to explain the cervical enlargement. In those cases where the glands enlarge days or weeks after may cause some confusion especially if the occurrence of a previous rubeola be unknown. In German measles the glands may be misunderstood until the rash appears. The mildness of the involvement coupled with the transient character of the enlargement makes the diagnosis easy.

The cervical adenopathy in syphilis is a part of a general involvement of the lymphatic system affecting the liver, spleen, inguinal and epitrochlear glands. Confirmatory evidence may be offered as a result of a positive Wassermann and the attending splenic and epitrochlear enlargement.

Then a history of a primary lesion or that of miscarriages, stillbirths or early deaths may aid in arriving at a diagnosis. The characteristic group involved in the neck is the posterior cervical. The nodes are discreet, with absence of inflammatory signs and

without being adherent to adjacent structures. No focus of infection can be discovered. If such nodes be excised they may show the spirochetæ pallidæ.

Hodgkin's disease may present a clinical picture at the onset which may be confusing. In Hodgkin's disease the cervical glands may be the first to become affected and oftentimes associated with some temperature. However, the constant and progressive enlargement with coalescing and without a tendency to suppurate will help to distinguish the condition. Furthermore, with the involvement of additional nodes, remote from the lymphatic system in the neck, particularly those within the thorax and abdomen, will also help to make a diagnosis. This will be made even more definite with the characteristic progressive anemia, and finding typical Hodgkin's hyperplasia upon section of a removed gland.

Of the leucemias the acute lymphatic form is the only one in which a cervical enlargement may need differentiation. In its early stages it presents enlargement of nodes up to a walnut size, discrete with little or no redness or tenderness. When hemorrhagic changes take place in the mouth and throat, infection is often superimposed upon the picture. The diagnosis will be made by the examination of the blood; anemia with one to three million red blood cells; hemoglobin of twenty to thirty per cent., and leucocytes from fifty to one hundred and fifty thousand, of which ninety to ninety-eight per cent. are lymphocytes. With this blood picture the diagnosis is simple.

Under the neoplasms that primarily involve the lymph glands the commonest form is the lymphosarcoma. Occasionally the cervical glands are the seat of this malignant growth. The process tends to spread locally and the glands enlarge very rapidly. The affection is unilateral rather than bilateral. There is a great tendency toward ulceration, but caseation and suppuration never takes place. Death occurs as a result of pressure, hemorrhage or cachexia. Internal metastasis to the liver and lung occur early, but involvement to other groups of superficial lymph nodes is unusual. Pathological examination of an excised gland definitely determines the diagnosis.

Secondary involvement of the cervical lymph nodes in malignant disease of the structures of the head and neck is common. In carcinoma of the larynx, the jaw, the tongue, the tonsils, the pharynx, and the esophagus, we have secondary carcinomatous involvement of the regionary lymph nodes. In all these conditions the diagnosis offers little or no difficulty since the original seat of trouble is so apparent.

Heterotopia of Central Nervous System in Relation to Malformation of Body Segments and Nervous Diseases

HENRY WINSOR, M.D.,

Haverford, Pa.

(*Continued from page* 332)

A. Bittorf's tables are overwhelming with proof of the effects of these anomalies, variations and embryonic malformations as predisposing factors not only towards tabes dorsalis, but also towards almost any nervous or other disease (56). Sibelius cites, Anomalies (of the spinal cord), in which degenerative signs possess the main worth for pathology" (57).

Church and Peterson illustrate the multaneous occurrence of syringomyelia and curve of the spine in two stances (58). In a third they illustrate the simultaneous occurrence of ringomyelia, heterotopia and bilateral symmetry of the spinal cord with citaons from Brissaud and Bruhl (59). ischel described and illustrated the multaneous occurrence of heterotopia, d curvature of the embryonic axis 50). The displacement of Clarke's column in our paralytic cases cannot be dependent on local pathological processes, but is connected with the series of phylogenetic anomalies (61). Clarke's column is at the base of the posterior horn on its inner side (62). The paths of conduction of vasometer reflexes are in the posterior horns of the side opposite (63). In regard to comparison of SGR variations in humans with those of beasts, we must absolutely concede that the lower forms which show a tendency to curve or spiral formation possess models in beasts, therefore the variations are in phylogenetic age direction (64). Nutrition of all tissues is controlled by the spinal ganglia (65).

The spinal ganglia lie in the intervertebral foramen. The sympathetic or vasomotor nerves are practically the visceral branches of the spinal nerves (66). Narrowing of the intervertebral foramen cannot occur without influencing the intercostal nerves (67). Bachman measured the intervertebral foramen and found it narrow in scoliosis

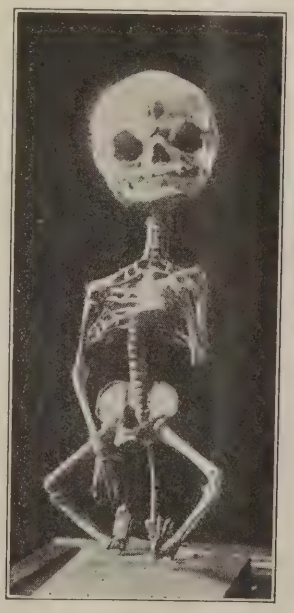

FIG. 13.—Newborn child's skeleton in Wistar Institute.

The remarks of Ivan van Gieson in *Artifacts of Central Nervous System*, do not apply to our insections, for he first removed the cord, thus juring it by making artifacts, while our transecms were cut in situ, after decalcifying the vertebae and imbedding them in paraffin, so that the ngenital deformity of the cord and vertebrae re both preserved.

FIG. 14.—Photograph by Mr. Erwin Faber of a moderate degree of kyphoscoliosis, laborer's spine, followed by lipping, thickening of the anterior common ligament, spondylitis deformans, rheumatoid arthritis of the heads of the ribs, narrowing of the intervertebral foramina, pressure and infections of the nerve trunks, atrophic cirrhosis of the liver, in other words, first curvature, later fibrositis of vertebræ, nerves and organs appended.

(68). "The sympathetic nervous system, then, when its normal action is disturbed, is the chief cause of the symptoms of disease" (69). Anomalies are equivalent to true diseases by the pernicious influence which they exercise on the organization (70). It is true that they can be the cause of each other (71). "The malformations precede the diseases," (in the embryo) (72). Of morbid agents not peculiar to the embryo, in the embryo we call them teratogenic, in the fetus and adult they are called pathogenic, but there is no sufficient reason for supposing that they differ one whit (73). The embryo tectonic curves become thus a criterion of the normal or abnormal character of this or that particular embryo (74). The study of pathological evolution should be sought as that of physiological evolution, in the true cause working morbid phenomena of the central nervous system or similar analogue which governs the higher movements of the organism (75).

PLACE OF LEAST RESISTANCE (LOCUS MINORIS RESISTENCIA)

The phenomenon of scoliosis should be considered universal (76). Axial anomalies are almost always accompanied by some deviation of structure in the appended parts (77). Variations are universal (78). Bilateral asymmetry is universal (79). Therefore all three are often if not usually dependent on a similar cause, i. e., the embryo tectonic curves of Boujard; or some similar curve and malformation of body segments occurring in adults causing cramped or distorted position of the torso. Further, as the variations or asymmetries are practically universal, according to three authorities, how could disease develop at any part of the body which had not previously varied from the normal, when most if not all parts do vary? With the exception of certain well known external forces such as trauma, which make a place of least resistance, a locus minoris in situ, the skin, e. g., not being adapted to resist the strain, the bacterial and other morbid agencies would find difficulty in developing at, or even in finding a part which had not already varied in an "opposite," i. e., nonadaptive direction.

So, "the nine hundred and ninety with unfortunate congenital variations are extinguished" (80), by disease growing thereon.

A very complete bibliography will appear in the author's reprints

Practical Therapeutics

THERAPY OF THE NONSPECIFIC PROTEIN REACTION*

Observations Based on the Intramuscular Injection of Venom Protein (Crotalin) Solution in Six Hundred Cases

RALPH H. SPANGLER, A.M., M.D.,
Philadelphia

For three decades and up to eight or ten years ago, specificity in medicine, i. e., the idea that resistance of the body to disease depends on biological reactions essentially specific, was so firmly inculcated by medical and laboratory teachings that my early reports (1), 1910-13, as to certain clinical results and laboratory findings following biological reactions, produced by intramuscular injection of venom protein (crotalin) solution, received little investigation to substantiate or disprove their value. Not longer than seven or eight years ago the suggested use of protein injections or the production of a nonspecific reaction brought forth caustic editorial denunciation and clinical results reported met with skepticism and were said to be "accidental or temporary." Criticism resulted largely from lack of knowledge concerning the mechanism of the nonspecific reaction.

Today, immunologists recognize nonspecific therapy as a possible factor in resistance to disease and some investigators, Much (2) for instance, writes, "Nonspecific resistance is of a greater importance to the organism than are the specific forces."

Wright, who introduced the opsonic index as a means of estimating the specific response on the part of the patient, wrote in the *Lancet* in 1919, "We should discard the confident dogmatic belief that immunization must always be strictly specific." He points out that immunization by nonspecific inoculation—"collateral immunization" as he terms it, is often of value.

Kolmer, in the third edition of his book issued recently, has changed the title to *Infection, Immunity and Biological Therapy,* using the word biological instead of specific. He includes a chapter on nonspecific protein therapy and points out that "Nonspecific activities of bacterial vaccine may exert beneficial and curative effects on disease to which the bacteria incorporated in the vaccine has no etiological relationship."

W. F. Petersen in 1922 published a book entitled *Protein Therapy and Nonspecific Resistance,* which is a comprehensive review of this new conception of the mechanism of recovery from disease. In the preface he writes: "A careful examination of protein therapy will reveal that nonspecificity is not as illogical, theoretically, as a cursory view might lead us to believe." He emphasizes the fact that the nonspecific reaction brings into play no new and heretofore unknown factors of resistance; that it deals largely with reactions previously studied and which have always been employed by the organism in overcoming disease, with or without our knowledge.

*Read before the Philadelphia County Medical Society, April 9, 1924.

THE NONSPECIFIC REACTION

The intravenous or intramuscular injection of a protein substance is followed by a certain amount of local and systemic reaction, which varies from a slight stimulation of the leucocytes to a mild or severe febrile reaction, with shock and vasomotor paralysis.

The reaction, according to Petersen, varies, first, with the form of protein used; second, its method of injection (intravenous, intramuscular, subcutaneous, etc.); third, its absorption; fourth, the strength of its dose; fifth, the type of infection or toxin with which we are dealing; sixth, the physical condition of the patient; seventh, the duration of the disease from which the patient is suffering; and eighth, with the number of previous injections.

In the early work with protein therapy, whether a bacterial, animal or vegetable protein was injected to produce a nonspecific reaction, much importance was placed on the local reaction at the site of injection. These local phenomena, it was thought, were necessary to produce the systemic effects. Much attention was given to the chill, degree of fever produced, variation in the blood count (red and white), nausea and vomiting, nervous manifestations and certain skin eruptions, e. g., herpes and urticaria. At times headache and delirium followed systemic shock from protein injection.

AGENTS USED TO PRODUCE NONSPECIFIC PROTEIN REACTION

In the past six or seven years a large number of organic (biological) substances have been used to produce nonspecific reactions for therapeutic purposes. Bacterial vaccines, diphtheria antitoxins, protein split products, proteoses, extracts from tissues, bee toxins, milk injections, etc., have been employed. Moreover, it is now recognized that other agents, such as serums, yeast, colloidal metals, as well as a number of drugs (turpentine, iodides) and even distilled water may be used to produce a nonspecific reaction for its therapeutic effect.

THEORIES AS TO THE MECHANISM OF THE NONSPECIFIC REACTION

Ten years ago clinical results of nonspecific therapy were hard to explain. Specificity in medicine was at its height and any results obtained with protein injections were considered to represent pure empiricism and were diametrically opposite to expressed conceptions of immunity.

Our knowledge of the specific factors of immunity is quite well established but exact information of the nonspecific elements is less definite. While specific immunization aims to influence directly the cause of the pathological process and is of great value in conditions of known etiology; nonspecific agents exercise their power by altering the reactivity of the whole organism through cell stimulation and tissue activation.

Renaud, 1911, was perhaps the first observer who was given credit for clearly pointing out a definite therapeutic result from the use of typhoid vaccine in

a number of inflammatory conditions of nontyphoid origin. In 1912 Krause and Ichikawa, working independently, reported startling results with the injection of colon bacilli serum in typhoid fever. These and subsequent clinical results, reported by Vaughn, Lüdke, Jobling and Petersen, Miller and Lusk, and many others, have modified our conception of strict specificity in therapeutics.

With the increasing clinical evidence of success the value of the nonspecific protein reaction is no longer ignored, and many workers have advanced theories to explain the beneficial results. Time will not permit me to review these interesting theories, but they all depend more or less on the production of two fundamental changes, viz., general cell stimulation, plasma activation, as Weichardt (3) explains it, and alteration of the permeability of cell membranes as shown by Starkenstein (4) and others.

RÔLE PLAYED BY THE LEUCOCYTE

It is only natural from our knowledge of the rôle played by the leucocyte in immune processes to study the leucocyte picture produced by the injection of bacterial, protein and chemical substances. To the reactive leucocytosis early was ascribed the therapeutic effect that often follows many of the nonspecific injections. Many investigators have found that this leucocytosis is frequently polymorphonuclear and practically all have reported that it is usually preceded by a primary leucopenia. It has been frequently pointed out, however, that the therapeutic effect does not run parallel with the general leucocytosis produced.

Lüdke, Rohanyi, Holler and others have observed an eosinophilia after protein injections, suggesting some relation to the anaphylactic picture.

Mueller (5), from his study of milk injections, calls particular attention to the occurrence of myelocytes and erythrocytes which he believes indicates a profound stimulation of the bone marrow.

In 1913 I pointed out (6), following intramuscular injection of venom protein in a series of fifty-seven patients who had received injections at weekly intervals for from three to six months, that no general leucocytosis was produced. I noted, however, a decided alteration or modification in the proportional relation of the cells in the differential counts for forty-eight or seventy-two hours following a venom protein injection, the most constant change being an increase in the percentage of eosinophile cells and a decrease in polymorphonuclears.

SELECTION OF A SATISFACTORY AGENT

Many workers have attempted to determine some agent that will produce satisfactory therapeutic results without marked local or severe systemic reaction. The selection of the best agent and a scientific method for regulating the strength of dose and frequency of administration are important.

In view of the recognized value of nonspecific therapy today it is desirable that we use a protein for clinical purposes which is chemically defined and the dose of which can be accurately measured. Having mentioned some of the substances used and referred briefly to the leading theories as to the mechanism of the nonspecific reaction, I wish to submit certain observations following the intramuscular injection of venom protein (crotalin) solution.

My clinical experience and laboratory investigations with venom protein solutions have covered a period of fifteen years. In nine or ten articles published since 1910 I have reported from time to time the effect of venom protein injection on the clotting time of the blood, its selective stimulation of the hematopoietic system and its effect on general body metabolism. In 1918 I reviewed (7) a series of three hundred cases of epilepsy in which intramuscular injections of venom protein had been given and pointed out certain nonspecific phenomena and therapeutic results.

Although my use of protein therapy has been largely confined to a series now totaling 612 cases of epilepsy, treated in private practice, it is not my purpose at this time to report on the therapeutic results, which have in many instances relieved or greatly improved the epileptic condition, but to recall that the use of venom protein (crotalin) solution intramuscularly is one of the earlier recorded instances of the employment of a nonspecific protein for definite therapeutic purposes; to report certain observations as to the mechanism of the nonspecific reaction and some of the therapeutic results produced in these patients, independent of the effect on epileptic manifestations.

CHEMICAL COMPOSITION AND EFFECT OF VENOM PROTEIN INJECTIONS IN ANIMALS AND HUMANS

In a paper (8) read June 3, 1912, after having used the venom solution for three years, during which time I had given over two thousand injections to 109 patients, I pointed out in reviewing the chemical composition of snake venom, that it belongs to the albuminoids and consists of two principal compounds, one a globulin and the other a peptone.

In testing the effect of these separate constituents upon the animal and human body ,Newman (9) found that the globulin element acted primarily on the blood and bloodvessel walls. The clotting time of the blood was lengthened and the permeability of the vessel walls increased. In lethal doses of venom in animals, the blood was found to lose its power of coagulation and passed freely through the bloodvessel walls into the surrounding tissues. The peptone element effected the nervous system and in large enough doses caused paralysis.

Mitchell and Reichert (10) described two protein constituents of venom: one of which seemed to be a globulin and the other a proteose or peptone.

Flexner and Noguchi (11) found enzymes in venoms, e. g., proteoses and liposes. They distinguished and classified the various elements as hematoxins, hemaglutinins, neurotoxins and endotheliotoxins.

Chemical analysis thus shows snake venom to be a protein substance, containing a proteose enzyme and it is physiologically standardized by the reptile itself. In view of the theories referred to above as to the probable mechanism of the nonspecific protein reaction, and when we consider that venom protein stimulates the hematopoietic organs, alters the permeability of the bloodvessel walls and lengthens the clotting time of the blood, it seems to meet practically every requirement chemically and physiologically as a satisfactory agent to produce nonspecific resistance for therapeutic purposes.

SOLUTION USED

Since my initial work in 1909 I have used the same venom preparation. The evaporated, dried, yellowish crystals, extracted from the crotalus horridus, are dissolved in sterile water and glycerine, to which is added enough tricresol to preserve and keep the solution sterile.

This solution is prepared in varying concentrations and put into sterilized ampules containing one c. c. each, representing 0.0025 grain, 0.005 grain, and 0.01 grain, etc. A bacteriological test is made to determine freedom from aerobic and anaerobic contamination. Culture media innoculated are allowed to incubate for seventy-two hours. That danger of infection from the solution is practically eliminated, is attested to by the fact that in using over 15,000 injections I have had no infections or deaths.

TECHNIC AND SITE OF INFECTION

The contents of the ampoule is given intramuscularly, using an all glass syringe and platinoiridium needle under the usual sterile precautions. After injection the site is covered with Turlington's balsam and sterile cotton. It has been my practice to give the injection alternately in the left and right forearm group of supinator muscles.

(*To be continued.*)

Effect of Light in the Treatment of Disease.—H. P. Wright (*Medical Clinics of North America,* May, 1924) states that all forms of tuberculosis, except active pulmonary and meningeal, are greatly improved by ultraviolet therapy. In active pulmonary tuberculosis and in tuberculous meningitis ultraviolet therapy is contraindicated. Bone tuberculosis, skin tuberculosis, tuberculous adenitis, tuberculous peritonitis, and pleurisy with effusion are among the forms most successfully treated. Rickets is, perhaps, the most outstanding example of disease, other than tuberculosis, which is successfully treated by ultraviolet therapy. Several skin diseases, such as acne vulgaris, psoriasis, pityriasis, and lupus, are strikingly improved. Ultraviolet therapy, therefore, has a definite clinical application in the treatment of disease. In the absence of heliotherapy, ultraviolet radiations from either the carbon arc or the mercury vapor lamp are the logical substitute; but, with artificial ultraviolet therapy, fresh air must be an important adjunct of the treatment.

Carbuncle and Its Treatment by Magnesium Sulphate.—Albert E. Morison (*British Medical Journal,* April 19, 1924) treats carbuncles by the application of a paste of magnesium sulphate to the whole inflamed area. The paste is spread thickly on a piece of sterile lint, which is in turn covered with a piece of jaconet and abundant cotton wool is applied over this. Eleven ounces of glycerin are put in a hot mortar and 1.5 pounds of dried magnesium sulphate are added, slowly stirring with a warm pestle, producing a thick white cream, which is very hygroscopic. The dressing is left unchanged for twelve or twenty-four hours and then renewed. After a few days the slough separates, leaving a raw granulating surface. The crateriform ulcer is dressed with this paste until all signs of sphacelation have disappeared, leaving a healthy granulating surface. The cavity is then packed daily and the undermined edges are supported with strips of sterile lint wrung loosely out of a saturated solution of magnesium sulphate (forty ounces of magnesium sulphate in thirty ounces of boiling water and ten ounces of glycerin, sterilized in an autoclave). After firm granulations have developed on a level with the surrounding skin the wound area is covered with Thiersch skin grafts or epithelialization is allowed to proceed if the granulating area is not too large. The advantages of this method of treatment are the following: 1. No surgical interference is required. 2. Its application is simple and dressing infrequent. 3. The combined osmotic action and its inhibitory effect on the growth and development of the staphylococcus cleanse the wound and aid in the separation of the sloughing and unhealthy tissue. 4. The granulations formed are firm and lend themselves admirably as a base for a superimposed skin graft.

Selfdefensive Reaction in the Treatment of Malaria.—Ivan I. Manoukhin (*Lancet,* January 26, 1924) asserts that biology must henceforward recognize that the premier rôle in the defensive struggle of the organism against infection and its toxins is that of leucocytolysis, and no longer that of phagocytosis. The latter never comes into play unless the microbes are greatly weakened and their toxins neutralized by the preceding phenomenon of leucocytolysis. The artificial stimulation of the selfdefensive power of the organism (selfdefensive struggle) is one of the recent methods of treating infectious diseases. The primary and secondary hypoleucocytosis following infection is subordinated to ferments in the blood, which induce the destruction of leucocytes; these leucocytolysins are produced in the spleen. Hyperleucocytosis is due to the presence of ferments in the blood which inhibit this destruction of leucocytes; these are called antileucocytolysins and are manufactured in the liver. The selfdefensive struggle is under the control of the spleen. The leucocytolysins produce not only hypoleucocytosis, but they also stimulate the leucopoietic activity of bone marrow and also the antileucocytolytic activity of the liver, resulting in hyperleucocytosis. Röntgenotherapy applied to the spleen, with a certain technic and dose, seems to indicate that the phenomena of stimulated selfdefensive artificial reaction produced in the blood alexin, hemolysins, agglutinins, bacteriolysins and opsonins. All the blood reactions observed in malaria are due to the leucocytolysis, the leucocytolysis being the cause of the selfdefensive reaction of the body to the presence of the malarial parasite.

Linimentum Calcis Chlorinatæ in the Treatment of Burns.—J. W. Tomb (*British Medical Journal,* April 19, 1924) uses a solution of chlorinated lime (linimentum calcis chlorinatæ, B.P.) in the treatment of burns with great satisfaction. The advantages of this method are the following: 1, rapid healing without pain; 2, the absence of suppuration or rise of temperature; 3, the disappearance of sloughing, dead, or decomposing tissue. This remedy has all the advantages of the antiseptic qualities of the hypochlorites and inherent virtues of the linimentum calcis.

Historical Medicine

The Use of the Kidney According to Galen

JONATHAN WRIGHT, M.D.,
Pleasantville, N. Y.

It has seemed to me, so far as I have become acquainted with references to Galen's work, too much has been said in vague and vapid admiration of the man and too little specifically of the merits which distinguish his work and the blemishes which disfigure it. Historical dissertation in regard to it has been far from critical and involuntarily the query has arisen whether in fact the indulgent critic has had much acquaintance with it, there existing no full translation into any modern language. His garrulity and combativeness, his vanity and his occasional prevarications it is not difficult to take note of, but it is singular that in this age of experimental medicine emphasis has not been laid upon him as a great experimentalist. Reflecting how eager is the pursuit of support for tendencies in modern science in the history of past thought one can not but come to the conclusion that in the Greek and Latin texts it has become practically inaccessible with the decay of a knowledge of the classics and an appreciation of humane culture.

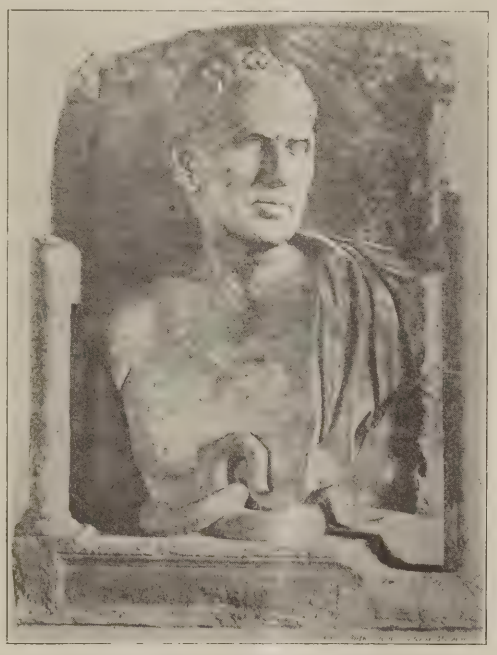
The pertinacity with which Galen belabors a point and his acerbity are repellent elements in his style, but it is vigorous and not infrequently lightened by flashes of innocent humor. Even the gall and wormwood of his acrid discourses on the work of his opponents and enemies, supplying us as they do with the only knowledge we have of writers evidently of great merit, have something human and even humorous in them. They have their attractions and to this spice of humanity in humane letters doubtless we owe something for their preservation as well as to the acuteness of their dialectics and their records of his ancient experimentalism. When he starts in to attack his fellow countryman from Bithynia, like himself a great professional success, each in the Rome of their day, he is often at his best. It seems to make no difference in the vitriolic nature of his attacks that his opponent had been dead a hundred years before he himself was born, though indeed we harbor the suspicion he often is silent as to his contemporaries for prudential reasons, yet unmindful of the generous admonition in Rome, *de mortuis nil nisi bonum.*

At any rate the name of Asclepiades, who was a friend of Cicero and evidently a very talented man, was anathema to him. It is well known to the student of philosophy that Aristotle invented an entelechy for every living thing and with it he filled in the gaps of his knowledge of their physiology. The vitalists have clung to that plan ever since. No one has made more profuse use of this principle than Galen, who approaches the question of renal secretion thus: "However many there may be who are not disposed in any sort of way or in any part to allow control of the power of attraction which governs living processes, they are often compelled to assert what is very much opposed to evidence, just as Asclepiades, the physician, did in the matter of the nerves, but every cook knows that the kidneys not only secrete the urine but concoct it, since they can see the veins going to the kidneys and the ureters connecting them with the bladder" (1). He takes Asclepiades seriously and furiously to task for declaring that when one drinks the liquid, resolved into the atomic waste of vapor, it is in this condition transmitted to the bladder and there takes on its old form of fluid. The obstinacy with which this was urged, according to Galen, was due to the ignorance of anatomists as to the valvelike action of the mouths of the ureters in the bladder. We can not fail to see in this record as to the ancient atomic theory that it was applied plausibly to explain an erroneous primitive idea of the route of the drink to the bladder. We have seen how probable it is not only that this error had its origin far back of any anatomical knowledge of abdominal anatomy, but it has seemed very likely that somewhat to this ancient error was due the Aristotelian idea that the bladder serves, not alone as a reservoir for the urine, but is the essential organ for its secretion, the kidneys being but ornamental adjuvants.

Galen, as has been intimated, distinguished himself from all his predecessors not alone in his eminence as a scolding controversialist and a skilful sophist but from Aristotle in being an experimentalist though far inferior to him as an observer. Empedocles was an experimentalist before Aristotle and upon much that Aristotle had from Empedocles he grounded some of his own theories. One of the fragments of the latter tells us how in the stem of plants and trees there is some mysterious power which draws for the plant the moisture and the food from the soil through the roots. I believe Bose, the Hindu botanist, has arrived by experimental investigations of the utmost delicacy at practically the same conclusion. In how far we have buried this idea in the word osmosis, I am not prepared to say. Aristotle evidently thought of the liquid man swallows and excretes by the bladder in the terms of the more accurate observation of Empedocles as to plants. At the bottom of Galen's physiology too lay this observation of Empedocles, nearly a thousand years old by that time. Galen however finds a path nearer the truth than Aristotle.

"Through the ureters in the living animal the urine very quickly flows to the bladder. This I have elsewhere been compelled plainly to show, hardly hoping to dispel the nonsense of those who deny it with their garrulity. This is the method of the demonstration: The peritoneum in front of the ureters must be incised. Then with nooses they are to be pulled up separately. Then turn the animal loose with his external wound bandaged. He can not urinate any more. After this take off the external bandage and show the bladder is empty, the

ureters full and distended almost to bursting. Then releasing the ligatures see the bladder quickly fill with urine. Upon this before the animal can urinate place a ligature around the penis and then press on the bladder on all sides. No urine will go back through the ureters any more toward the kidneys. It becomes evident then not only in the dead animal, but in the living, the urine is at once prevented from going back to the bladder by the ureters. These things having been seen, allow the animal to urinate, loosing the ligature on his penis. Then immediately tighten the ligature on one or the other of his ureters and permit the other to be permeable to the bladder. Allowing some time to pass show that the ureter which is ligated appears full and distended in the part below the kidney and the other one, unconfined, is not only slack but has filled the bladder with urine. Then cut through first the full one and show how the urine shoots forth like the blood in phlebotomy. After this cut also the other and put the external bandage on the animal, both ureters having been divided. Then when it seems suitable take off the external bandage. The bladder will thereupon be found to be empty. All around the intestines and in the peritoneum it will be full of urine, as if the animal were dropsical. Thus if any one for himself should wish to prove it upon the animal, it seems to me very decidedly he would be convinced the talk of Asclepiades is foolishness." (1a)



AN UNKNOWN ROMAN PHYSICIAN
(From *Plastik und Medizin*, Holländer)

It seems a little strange that Galen does not specifically hold up to refutation here the idea of Aristotle that the bladder secretes urine. In the experimental work just quoted is to be found a fairly conclusive refutation of it, but he does not mention him in this connection, though manifestly he must have had him in mind. Apparently he was somewhat awed by his name, though we find him criticising the ideas of Aristotle oftener than we do those of Hippocrates or Plato, but to his support doubtless we owe the complacency and cocksureness with which he views the doctrine of physiology by fiat, for that is what, laying aside the ridiculousness of the tautology, it amounts to when one says an organ attracts by virtue of its attractive force.

Galen says (1b) Lycus the Macedonian advanced a theory that the urine was the superfluity of the food digested for the nutrition of the kidneys. This he ridicules and from a theoretical point of view he demolishes it. In the book on the diseases of the kidneys (2), which Kühn says is ascribed to Galen, that idea is accepted as a physiological basis of discussion. This book therefore can hardly be considered as coming from the hand which wrote the *Natural Faculties,* and Galen was undoubtedly the author of this. From the style alone of the book *On the Diseases of the Kidneys, Their Diagnosis and Cure,* one familiar with the genuine books would hardly recognize it as that of Galen. However, it is well written and a very able treatise. Although in it we find the tautology of vitalism, it may seem singular Galen did not include this in his ridicule, if this was indeed written by Lycus the Macedonian, but the tautology of vitalism is a part of the absurd that was not ridiculous to Galen. The author of this book declares: "There is an energy in the kidneys to distinguish the watery urine from the blood. There is a certain suitability in them. This is to be sought for, not alone in the kidney, but it is the energy of every part. This injured, disease affects the part." *Voila que votre fille est malade.* Molière saw grist for his comedies in such stuff.

Galen is usually not so easy a mark as this. He finds (3a) difficulty in reconciling the phenomenon of polyuria in diabetes with the idea it is due to excessive attractive power. How then does the kidney give up the urine to the bladder? He likens this, without throwing much more light on it, to the dog like voracity for food, when large quantities are swallowed, but soon vomited or expelled in diarrheic discharges. The voracity of the kidney for the watery serum of the blood then is not in diabetes antithetic to its passing it on to the yearning bladder, but excessive hunger or attraction for food is partly psychical, as coming within the scope of our consciousness, but not so the secretion of the urine in the diabetic kidney. If Galen could have had cognizance of Pawlow's experiments he would have seen how intimately the psychical and the physical art intertwined. He would also have known that certain psychical stimuli are without consciousness effective in increasing the secretion of urine, indeed many other things.

Yet however many there are Galen did not know we still not infrequently employ tautological terms that have a vitalistic meaning and it is safe to prophesy we shall never get away from it, for behind all the mysteries that have been and all that surely will be cleared up will lie a mystery still, but it is in the last degree deplorable that the human mind, confused when it loses the path, should be ever declaring its own impotence. We see some of the confusion is bound up with a sophistical curiosity to know when intake becomes outgo, when attraction becomes expulsion. At times it seems as though the thought is that the dryness draws the wetness. From his remark that the food has an influence on the intensity of this attractive power of the kidney we may conjecture he had observed the effect of starches and sugars in diabetics. This at-

tractive force from the very first gulping down of the food to the secretion of the urine is all one thing. There is an excessive desire for food and drink in some cases without diabetes, so that without any systemic disturbance and without over nutrition two or three times as much food is taken in as is ordinarily consumed. The abnormal desire for food and drink thus enters into the complexes of diabetes and watery diarrheas. It is all essentially an attraction process.

Since the laws of osmosis were unknown, it must be remembered there was no way to explain, better to say there was no way to trace the movements of some of the secretions to their destination, but in "osmosis" we have substituted a word which we understand no better. We are dropping that and taking refuge in "surface tension" which we understand less. The essential point is, however, in making use of a mystic term just as we do now. Galen dislocated it, applied it less exactly, oriented it wrongly (3a). It was the gallbladder, not the surface demarcation between one cell and another, that drew the bile from the liver, the urinary bladder which drew the urine from the kidneys, but he got closer to it when he declared it was the stomach that drew the nourishment from the food and it was the kidneys drew the urine from the blood. This it will be seen falls somewhat in line with modern methods of thought, but it would be more difficult and less instructive to search out the connection between this mechanism and the desire for food, though Pawlow has advanced close to each side of the gap which separates mind from matter. All of Galen's physiology is based, possibly through Aristotle, on the conception we find in the scanty fragments we have of Empedocles observing the moisture and nourishment rising from the soil through the roots of the plant stem to the periphery of the leaf. Bose, the Hindu physiologist, as I have said, with marvelously sensitive apparatus has fixed this mystic power, over which he lingers with the love of the true oriental, in the cell structure itself. He has not only located it but measured its potential. We shall, however, have to leave him to the mercy of the physicist and the materialist, and not attempt here to draw any distinction between "attractive force," "osmosis," "surface tension" and mysticism.

It is a little hard to understand what connection there is physiologically between the convexity of the liver and the kidneys, but according to Galen they are both relieved in disease by evacuation through the urine (4), that the excretion from the superior convex surface of the liver is through the kidney. On the other hand from the concavity of the liver the excrement goes out through the intestine. The spleen, too, as we have seen in Aristotle and Hippocrates, also for Galen draws water from the stomach and in his thought had a connection with the excretion of urine, just how it is hard to say, but I imagine the hard tense capsule of the top of the liver, of the spleen and of the kidney led to his thought of their affinity.

In a book (5), discussing the theories of Plato and Hippocrates, Galen traces out his theory of the excrementitious organs, established by the wisdom of nature for the purification of the body from the superfluities of the blood resulting from concoction or digestion—the kidneys, the spleen, the gallbladder, "there is no fourth." Elsewhere (6) he declares there are three coctions in the veins, one of the yellow bile, the second of the black bile, the third the serous. The gallbladder draws the yellow bile out of the liver, the spleen and the kidneys their secretions. We hide our mysticisms under various names, but Galen certainly does not, as Sir Clifford Allbutt (7) remarks: "cast aside the oriental cosmogonies unconditioned and based upon the fiat of God." Far from it, he is, as insistently as Plato, bringing in the fiat of God to help him out of difficulties. It is astonishing to find the learned and gifted modern author commending in this connection "his insight and theoretical capacity." It is true he does not everywhere lay himself open so unguardedly as the author of the book on kidney diseases—"The retentive faculty retains that which is useful and rejects that which is useless" (2)—but his teleological philosophy leads him into a tautology scarcely less ridiculous in many places even of his greatest work—*Utility of the Parts*. Though he constantly speaks of Nature as a demiurge, it is not at all in our spirit of rationalism but in one of pantheistic mysticism. That sort of thing is essentially something which can not be got rid of. Something must stand for the unknown if not the unknowable. What difference whether it is attractive force or surface tension? The significant thing here, in passing from Aristotle to Galen, is that the latter drops the bladder as a secreting organ in the sense Aristotle uses it, but yet, since it had even for Galen an attractive force, we here strike the trail of Aristotelian physiology. If we note an advance here in his edging away from the original form of the doctrine, he repeats Aristotle's error in stating that the right kidney is higher than the left and the vein and artery to it come away at a higher level from the Vena Cava than the vessels on the left. This is true of animals but not of man. Elsewhere (8) he has shown experimentally, in acrid refutation of Erasistratus, that the arteries contain blood and here pointing out the arteries have their insertion in the kidneys he asks: "If they are not there for the purpose of having the blood purified in them, will any one tell me why Nature has made these so large and divided them up in the cavity of the kidney and acted with them not otherwise than with the veins? They are for separating the serum from the blood and this is the reason of their great size" (9).

Then comes the very interesting and withal ingenious explanation why one kidney lies higher in the abdominal cavity than the other: "If each of them exerting their attractive force on the serum of the blood should have the bloodvessels (going to them from the aorta and vena cava) given off opposite one another they would be pulling against one another." We should state the problem inversely. It would be the impulse of the current in each from behind. Either way however a modification in hydrostatics would seem to follow if the vessels were arranged thus. Our anatomists say that it is because of the liver this inequality obtains in man, the right kidney in reality being lower, but both

Galen and Aristotle speak of it as higher. In animales, even in apes, this is said to be so. We save ourselves a deal of trouble in refusing to be interested in teleological anatomy, but it was from that angle the ancient anatomists studied it. Their dissection confined as it was to animals is responsible for this divergence, but the modern anatomist in regarding the liver as the cause of the right kidney being the lower, even venturing thus far into teleology leaves something to be explained in the anatomy of animals. Indeed there is no reason but one of hydrostatics, it would seem, why the left kidney is not lower and opposite the right. So, essentially after all, Galen's surmise that hydrostatics is the chief element in the problem, seems not far wrong, despite his mistake as to the anatomy of man. His explanation why there are two instead of one kidney, one reason offered being that it is to preserve the equilibrium of the body, calls for no serious discussion. It is probably true that it is a safeguard, one kidney at times being capable, when the other is disabled, to do the work of two, but, from a teleological point of view, we can hardly argue thus, a a single stomach, liver, spleen, being in our road Black bile from the spleen and yellow bile from the liver find their way, the one through the left, the other through the right kidney, to the bladder in the urine, but we should go too far afield to enter into the Galenic physiology of the liver and spleen. He concludes it is the density of the kidney substance which under normal conditions may be credited with accurately separating the thicker red part of the blood from the watery urine. This also has lost its interest for us, though possibly we might twist our own thought into line with that of the ancient physiologist. At any rate the reason of the surmise on his part is not far to seek.

Contributors to the Science of Medicine

Benjamin Rush

Benjamin Rush was born, of Quaker parentage, near Philadelphia on December 24, 1745. He received his schooling at Nottingham Academy, from whence he went to Princeton University, graduating in 1760. The following six years he devoted to the study of medical science, and was a member of the first class to attend the celebrated lectures of Shippen on anatomy. In 1776 he went to Edinburgh, where he received his medical degree in 1768. The next year he was called to the chair of chemistry in the College of Philadelphia, which in 1791 became the University of Pennsylvania. Rush was made professor of the institutes and practice of medicine, and his fame as a teacher has lasted until our own day.

When the medical department of the Revolutionary army was reorganized in 1777, high sounding titles were instituted as an inducement to attract the best type of physician for military practice. There was a director general of the medical department, there were physician generals of the hospitals, surgeon generals of the hospitals, and physician and surgeon generals of the army. Rush received the appointment of surgeon general of the hospital in the Middle Department. This was the first time the title of surgeon general appeared in the American service. After only three months, however, Rush was transferred to the position of physician general when Dr. Walter Jones resigned from that office. Able as Rush's work as a military medical officer was, it was greatly overshadowed by his work as a teacher and civilian practitioner.

Rush was a member of the Continental Congress of 1776, and one of the signers of the Declaration of Independence. He also served as treasurer of the national mint for the fourteen years preceding his death. He was deeply interested in all state and educational matters and was a leader in the improvement of medical service for the Revolutionary army. He was able to accomplish much toward progress in military medicine through his office as surgeon general of the Pennsylvania army. Rush was an intimate friend of Director General Morgan and a strong supporter of his policies. He was just as strongly opposed to his successor and rival, Director General Shippen, even going so far as to prefer against Shippen formal charges of abuses in the medical department, upon which, however, there is no record of any final action ever having been taken.

He was one of Pennsylvania's greatest and most active educational leaders. His earlier energies were devoted to establishing and promoting the University of Pennsylvania, in whose welfare he always retained the most profound and active interest. His devotion to this institution did not prevent him, however, from realizing the great need of a college farther west in the State, and it was through his efforts and inspiration that Carlisle

College was founded upon what was then the far frontier of Pennsylvania. John Dickinson, another great patriot of the Revolution, at that time Governor of Pennsylvania, was his coworker in founding and promoting this institution.

Rush's broad interest in everything that had to do with progress and enlightenment is further evinced in his championship of the cause of the abolitionists and his numerous published speeches and writings against slavery. He was also intensely opposed to all form of capital punishment, and spoke and wrote fervently in behalf of the abolishment of punishment with death or even of murder. His brochure entitled *Inquiry into the Justice and Policy of Punishing Murder by Death* is one of the finest and most brilliant contributions against capital punishment ever produced by the pen of an American. He championed with equal ardency the cause of temperance and that of the antitobacconists. His two monographs on these respective themes were widely circulated and read by both the laity and the medical profession. These were respectively an *Inquiry into the Effects of Ardent Spirits upon the Human Body and Mind,* and *Observations upon the Influence of the Habitual Use of Tobacco upon Health, Morals and Property.*

Dr. Rush was a most prolific writer and speaker. His account of the epidemic of yellow fever in Philadelphia in 1793 was probably the best known of his medical writings to his contemporaries, and is still a medical classic. Other famous treatises were his *Defense of Bloodletting* and that on *Diseases of the Mind.* One of his favorite sayings was: "Medicine is my wife and Science my mistress." Dr. Oliver Wendell Holmes wrote of this statement, "I do not think that the breach of the seventh commandment can be shown to have been of advantage to the legitimate owner of his affections." Dr. Rush's papers on the diseases of North American Indians (1774), their vices (1798), and his account of the Pennsylvania Germans are probably the earliest contributions to American anthropology. He was the first after Bylon of Java to describe dengue fever, and the first to record thermal fever caused by drinking cold water when overheated. Rush was by far the ablest clinician of his time, and his fame extended throughout Europe. Lettsom called him "the American Sydenham," and his own countrymen "the Hippocrates of Pennsylvania." Royalty of Europe bestowed upon him many medals and a large diamond.

Benjamin Rush was a man of warm, almost intense personal affections; his friends were legion and drawn from all types of person and from many nationalities. He was a man of exceptional charm of manner, and of handsome and distinguished appearance. His profile was aquiline in outline, and his face expressed native shrewdness and penetration and a brilliant and everactive mind. With all his popularity, however, he was a man of decided opinions and absolute courage, as is shown by his campaign against Shippen, and his desertion of Washington at Valley Forge to join the infamous Conway Cabal against Washington's socalled Fabian policy. He sometimes tended to become unreasonably stubborn and even showed bad judgment in upholding a fixed and at times wrong opinion. His critics have called him a typical eighteenth century theorist, whose social propaganda against war, slavery, alcoholism, and the death penalty was perhaps not entirely dissociated from a personal interest in increasing his own practice. But his friends were equally ardent in his defense, declaring him to be not only the ablest physician but also the most disinterested reformer of his time.

When several years ago the question came up of erecting a statue in Washington to a representative American physician, the name of Benjamin Rush was immediately proposed. The plan was fostered for years by one of his distinguished successors in the national medical service, Commodore Albert L. Gihon, Medical Director, Retired, in the United States Navy, and fourth President of the Association of Military Surgeons of the United States. Unfortunately Gihon's death deprived him of the pleasure of witnessing the dedication of the statue in 1904, but the unveiling of the monument was attended by a large and representative body of physicians from all parts of America, and it now stands in the national capital as a testimonial to the distinguished services of the first titular Surgeon General in the American Army.

The Multiple Personality of Dr. Guy Patin.—Dr. Joseph W. Courtney (*Annals of Medical History,* March, 1924) writes that "the seventeenth century was the farce-comedy era in the medical history of France. Of all the actors who held the stage no other is quite as interesting, no other played as many rôles as did Dr. Guy Patin, son of François Patin, onetime advocate in the parliament of Paris." The interest in medicine first came into the young Patin's life when he was a proof reader in a printing firm. Here he was discovered by the great anatomist, Riolan, who encouraged the boy to study medicine. In order to do this in those days, Dr. Courtney tells us that four qualifications were necessary—a sound knowledge of Latin, unremitting application, a prodigious memory, and a habit of thought guiltless of even an infinitesimal taint of originality. Patin qualified in every particular. "In 1627 he became the proud possessor of the doctor's bonnet, and from that moment to the end of his long career, in 1672, a new side was conspicuous in his character. This pertained solely to his professional tenets and activities. In these he was Hippocrates *tout craché,* to use an expression current in his native Picardy. So much did he fancy himself in this rôle that he aped as far as possible the severe and simple garb of the wise man of Cos. The lancet and purge, consisting of senna, cassia, rhubarb and syrup of pale roses, constituted his entire therapeutic armamentarium." Had Patin not wielded the pen almost as frequently as the lancet, however, probably has name would long since have disappeared from the annals of medical history. He wrote letters, nearly two thousand of which are extant, and the contents of these as a whole give little evidence of the paragon of all the virtues who is depicted in the collection of letters edited by Reveillé-Parise which appeared in 1846. Here he is shown as a noble, publicspirited

citizen who scorned wealth and position, and who raised an angry voice against the sufferings of his fellow citizens and fatherland through the rapacious greed of wealth and power. He is shown as the exact opposite of the baseness, corruption and brutality of his day. The letters themselves, however, depict Patin as occupying, throughout the famine stricken period of the Fronde, a house in the most fashionable quarter of Paris, beautifully located and far from the turmoil of the city. He boasts smugly of being amply provided to withstand a siege of any length. Here he sat and played Erasmus, seizing an opportunity too good to be lost for retaliating for what the Church more than a century before had done to his venerated idol, and attacking the followers of Loyola, the while luxuriously seated at his desk and far from the heartbreaking turmoil of the times. There is no more individuality in his tirade than in that against the publishers against whom he is constantly inveighing.

Long parades of selfdenial and disdainings of mundane pomp and display ornament all his writings, yet in life he fawned most unctuously upon rich and prominent men, and boasted of the use of their equipages, his visits to their homes, and the welcome he was acorded there. So good a storyteller was he, however, and so startling and entertaining his confabulations, that there was a story current that every time he sat at the table of M. Lamoignon, president of the parliament of Paris, he found a louis under his napkin.

Patin was brutally cynical about women, but, probably because of his great craving to be recognized as an author, he knew the whereabouts of all the printing presses, in those days identical with publishing firms, in Europe; he was acquainted with all the booksellers and with the book markets of England and the continent; and he knew the size and contents of every private library of note in the capital. He had upon his own shelves all available editions of the fathers of medicine, all the commentaries and commentaries upon commentaries, and the works of men nearer to his times, as well as all the classics—nine thousand volumes in all, he tells us.

The Conflict of Medicine with Quackery.—Dr. Walter R. Steiner (*Annals of Medical History*, March, 1924) writes that rational medicine founded upon observation was unknown until its introduction by Hippocrates. At that time the profession was largely hereditary, and Hippocrates is said to have been the seventeenth in lineal succession from Æsculapius. There were no specialists, and, with the possible exception of India, no legal requirements in force until the thirteenth century. In India we find in the Ayur Veda, dating from about 600 B.C., the statement that the medical candidate upon completion of his studies must petition the king for permission to practise. Even Hippocrates berates those who rely upon amulets and charms to cure. For many centuries Greek medicine ruled supreme, but Roman fell into disrepute for the physicians were for the most part a motley gang, including augurs, *schoenobates, medici, magi.* Exceptions were Antonius Musa, physician to Augustus, and friend of Horace, Vergil, and Maecenas; and Meges, praised by Celsus. Thessalus, Nero's physician, is reputed to have tried to make doctors in six months of cooks, dyers, spinners, weavers and cobblers.

Between the seventh and eighth centuries, a medical school was founded at Salernum, Italy, which soon became renowned. A hospital was founded in connection with it in 1820, and its teachers were the first medical physicians to culture medicine as an independent branch of science. The first attempt to organize medical men into a profession came from this school, and Robert of Sicily in 1140 promulgated an ordinance to regulate the practice of medicine. Henri de Mondeville, surgeon to Philip the Fair of France, brought about the establishment of an edict against unqualified practice in 1311. In the fourteenth century, specialists were rampant, some practising with a license, some without. Quacks and mountebanks went about France, advertising themselves and practising their "cures" in the market places.

In England the first attempt to obtain legal control of medical practice was made in 1421, but with no results. In 1511, however, an act was passed for the regulation of medical and surgical practice, but so much dissatisfaction arose from this act that it was modified so greatly that it was practically annulled. In 1518 the College of Physicians was founded with absolute control of false medicine and practice, and the power of committing to prison all quacks and to seize their wares. From this time most of the countries of the world have had many laws against the practice of quackery, more or less stringently enforced.

Among famous quacks whose careers are outlined by Dr. McFarland are Lucius Horatillavus, the famous Roman charlatan; Valentine Greatrakes, with the touch for the King's evil; Sir William Read, Chevalier Taylor, and Dr. Roger Grant, quack oculists; Joshua Ward, known as Spot Ward, politician and promoter of many fake remedies; James Graham, quack oculist and aurist of Philadelphia, who later went to London where he opened his "Temple of Health"; and St. John Long, Irish painter, teacher, and compounder of many concoctions; he mentions Mesmer, Cagliostro, the Taylor brothers, Mr. and Mrs. Loutherbourg, Mrs. Mapp and Joanna Stevens.

The article is concluded with an account of the provisions and laws in the United States against the practice of quackery, from 1736 when the Virginia Assembly passed an act for regulating the fees and accounts of the "practicers of physic," to the present day propaganda on the part of physicians and medical journals to combat this evil.

Dr. McFarland quotes for the purpose of showing why quackery is universally possible and even popular from the *Regimen Sanitas* of the school of Salernum:

> There is no fool whate'er the sex or grade
> . . . . . .
> But has his name among wise Doctors placed
> And thus through greed the Healing Arts disgraced.

Also Dr. John Brown's famous definition: "Quackery and the love of being quacked are in human nature as weeds are in our fields," is also quoted.

Editorial Articles

THE VALUE OF LIGHT

The therapeutic value of light has been more or less recognized for centuries, but its really remarkable healing and recuperative properties are now being more thoroughly gauged. There are few maladies which are not benefited by sunlight, among these rickets may be placed in the front rank, and few diseases which are not injured by its lack.

A fair and impartial estimate of the value of sunlight is given in a paper on heliotherapy contributed to the *Boston Medical and Surgical Journal,* August 7, 1924, by R. Plato Schwartz. He says that although sunlight is not equally effective for all patients, its use, under widely varying climatic conditions, has defined definite advantages over other forms of therapy which makes it a therapeutic agent of the first consideration in the treatment of osteoarticular tuberculosis. According to Rothier, the chief apostle of the light treatment, Bernhard, of Samaden, began to expose patients' affected extremities to sunlight in 1902. In the following year Rollier at Leysin advocated and practised the treatment of extrapulmonary tuberculosis by systematically graduating the exposure of the whole cutaneous surface to the sun's rays.

Sir Henry Gauvain, at Alton, England, the late John H. Pryor, Clarence Hyde, and Horace Lo Grasso were the first to demonstrate that heliotherapy could be successfully used in England and the United States.

Dr. Schwartz states the prophylactic value and therapeutic indications for systematic, graduated exposures of the entire body surface to sunlight in the mountains, on the plains, and at the seashore has become well established. Dr. Schwartz, after reviewing at some length the indications for treatment and the methods of treatment for osteoarticular tuberculosis points out that the failure of restoration of function in tuberculous joints in the past has been due to: 1. The destructive character of the disease, which reached wide limits because it was opposed only by the unstimulated defensive mechanism. 2. The long continued application of plaster and similar apparatus resulted in such complete atrophic degeneration of specialized structures that ankylosis was necessarily a desirable outcome. 3. The absence of therapeutic measures which were effective in overcoming the systemic infection while the local lesion apparently recovered, not only favored recurrence, but predisposed the patient to more severe manifestations of the disease elsewhere. The conclusions are as follows:

1. Thirty-three years have not produced universal confidence in the use of tuberculin in the treatment of any form of tuberculosis.

2. Heliotherapy has clinically proved the indications for its use on the basis of the general changes in the patient, the prevention of deformity, and the restoration of function in the affected joint, providing that fundamental orthopedic requirements are met.

3. High altitudes have a certain advantage, but excellent results are being obtained at the seashore; at either level clean clear air is a necessity.

4. Systematic, graduated exposure of the entire body, except the head, with careful observation of each patient as the period and extent of insulation is increased, seems to be of fundamental importance in any serious attempt at heliotherapy.

5. Clinical observations and laboratory investigations, at present, favor the opinion that the therapeutic value of the solar spectrum is not due to the effect of any one region; but is more the result of the combined effect of the entire spectrum.

6. Artificial sources of light are to be regarded with suspicion until it is proved that they reproduce the solar spectrum in extent and intensity.

7. The local lesion in the bone or joint should be completely immobilized during the acute stage; apparatus is indicated but should not interfere with insulation. Sinuses and ulcers should be unbandaged twelve hours out of the twenty-four and subsequent treatment should favor the restoration of function.

8. Surgery must be looked upon as occasionally essential in the conservative attitude towards the treatment of osteoarticular tuberculosis, but to use it wisely requires a knowledge of when conservative measures have reached their full potentiality in each individual case.

This seems to be a fair consideration of the value of heliotherapy in the treatment of surgical tuberculosis. It will be noted that the author is sceptical as to the value of those lamps which do not come up to the predicates laid down in his conclusions. For example, he is doubtful that lamps which give off essentially ultraviolet rays can fulfill heliotherapeutic requirements. It may be asked, Is there any form of artificial light which does fulfill these requirements?

It has been stated on several occasions that artificial light of a certain kind is practically as effective in its results on surgical tuberculosis as heliotherapy. This is a matter which should be decided as quickly as possible. Schwartz definitely states that both the mercury vapor lamps and the ordinary carbon arcs

ailed to give sufficiently good results to justify continuing their use. On the other hand, it is stated hat results reported by Ernst from the Finsen Institute were obtained entirely by the use of artificial ight and in some respects are better than those reorted by Rollier, who is admitted to have almost deal natural conditions. Were the results by Ernst btained from artificial light which comes up to the ostulates of Schwartz? This is a very important oint, for while heliotherapy may bring about good esults in low altitudes, the lack of sunlight suitable or treating tuberculosis is more likely to occur in ow than in high altitudes and therefore artificial ght is more called for in cloudy places than in comaratively bright. Dr. Schwartz says that a proper ource of artificial light seems to be indicated in intitutions where conditions are most favorable for dministering heliotherapy, but the proper source of uch light must be known. However, it is most enouraging to know from irrefutable proofs that surical tuberculosis may be greatly benefited by helioherapy employed scientifically and expertly.

As E. L. Tushy said in a paper read on June 27, 924, before the medical staff of the Lymanhurst chool for Tuberculous Children and the Parkview anatorium, "It is increasingly more evident that ven such simple procedures as the application of eliotherapy, Alpine light, ordinary sunlight, cannot be done in a hit or miss manner, but must be onscientiously and carefully supervised by those who now what they are doing."

MONGOLISM IN EUROPE

The descent of man has ever been a much discussed ubject among men of science, and one that is yet good deal of a mystery. A study and consideration f Mongols in western Europe has been written by r. F. G. Crookshank of London, and given to the ublic. The title of the book is *The Mongol in Our Midst, Study of Man and His Three Races* (London: Regan, Paul Trench, Trubner & Co.; New ork: E. P. Dutton and Co.) and it deals with the currence in western Europe of individuals of the ongolian type, a type ranging from the congenital iot to that of the person of slight "mongoloid" haracteristics, but who possesses frequently intellince considerably above the normal, and especially rhaps literary and artistic talent.

There are numerous people of non-Mongolian race ho carry with them many of the physical facial tributes of the racial Mongolian, who live not only western Europe, but in various parts of America. r. Crookshank has set himself the task of arraying e facts bearing on the matter in orderly sequence, id of putting forth a hypothesis, perhaps pointing a moral. He points out that the pioneer, at any rate in Great Britain, in this line of research, was Robert Chambers in his book *Vestiges of the Natural History of Creation,* published in 1844 and which, by the way, as Darwin himself confessed, suggested to him *The Origin of Species.* A prominent part of Chambers's theory was that parents too nearly related tend to produce offspring of the Mongolian type, that is, persons who in maturity are still a kind of children. Dr. Langdon-Down, a well known London physician, some twenty years later, suggested the classification of idiots and imbeciles by their "ethnic character."

Langdon-Down declared that in Great Britain are met some idiots and imbeciles who appear to belong to the Ethiopian or Negro variety of the human race, others who resemble Malays, and so on, while "a very large number of congenital idiots are typical Mongols" and can be fairly referred to one of the great divisions of the human family other than the class from which they have sprung."

The name of Mongol is now used in every British hospital for children and every asylum applied to imbeciles of the kind that he first distinguished with precision. Langdon-Down's general ethnic classification of imbeciles has been forgotten and there has been a recent tendency to assert that Mongolian imbeciles do not resemble racial Mongols in spite of the fact that Langdon-Down defined the class described by the obvious possession of characteristics of racial Mongols. Crookshank's object is to show that Langdon-Down was right and that really it is the Mongolism rather than the idiocy that it is important to stress. In his opinion the Mongolism that is so evidently displayed by a proportion of the indigenous population of western Europe, and he might have said of America, is far from being a mark of idiocy or imbecility, but is a kind of physical and psychical make up that is coarsely and brutally displayed and accentuated in certain idiots and imbeciles.

Crookshank explains and develops his hypothesis throughout the book with admirable lucidity, giving careful consideration to the ethnological distribution of Mongoloid imbeciles and nonracial Mongols having indications of simian traits. Another chapter deals with the homologies found between racial Mongols, the orang-outang, and the Mongolian imbecile. Moreover, he suggests that homopogies may exist between certain white races, the chimpanzee and cases of dementia precox, and also of a similar state of affairs as regards the negro, the gorilla and the mental defective of Ethiopic strain. Posture and handmarking are dwelt upon emphatically as well as physiological and anatomical characteristics. In the last chapter he brings forward the theory that an hypothesis of common descent for all the homologous

individuals, men, apes and imbeciles, may explain all. It seems that the hypothesis is worthy of close investigation, as the case for the opinions propounded by Crookshank is strong and, at least, has more to commend it than some of the theories now advanced, as much, for instance, as the elucidation by gland balance which appears now to hold the popular scientific fancy.

Professor Klaatsch suggested a scheme of descent in which he placed together as proceeding from the same stems the three main human types, and the three types of anthropoid apes. In this suggestion he was supported by Sera, who emphasizes the facial resemblance between racial human types and the various types of apes and monkeys. As a matter of fact, Sera's views are in accordance with much of what has been pointed out in the book discussed in this editorial, and which, while they have gravely disturbed orthodoxy, have given students furiously to think. And after all, as Crookshank sagely says, Langdon-Down's brilliant observation, that an ethnic classification of imbeciles can be sustained still stands.

LONGER LIFE

According to Mr. Harold A. Ley, president of the Life Extension Institute, the life of the human race has been extended twenty years during the past century. This is to say, that while the average person could only expect to live to be thirty-five years of age, one hundred years ago, he can now expect to live to be fifty-five years old today. Men at all ages die earlier than women, and people living in the country show the greatest longevity. Occupation has a great deal to do with long life, some trades and even some professions being obviously more unhealthy than others.

The general death rate among industrial workers between the ages of fifteen and sixty-five, as estimated on the basis of mortality experience of life assurance companies for 1920, is 10.10 in 1,000 living. Among graduates of women's colleges, it is only 3.24. Clergymen live long, lawyers not so long, while the medical profession is comparatively not conducive to longevity. It appears that the highest mortality is, or rather was, in this country at any rate, among collectors and traveling salesmen for breweries. Since 1900 the general death rate in the United States has fallen from 17.6 in 1,000 to 13.1 in 1,000.

Judging from the annual report of the Chief Medical Officer of the Ministry of Health for 1923, the figures for England and Wales are yet more remarkable. In that year both the death rate and infant mortality rate were the lowest on record, 11.6 in 1,000, and sixty-nine in 1,000 births respectively.

Public health measures have practically eliminated most of the deadly contagious and infectious diseases. For example, since 1907 there has been a decline in the death rate from tuberculosis in this country of eighteen per cent. Typhoid fever rate has shown a drop of fifty-five per cent. during the same period. Vaccination has abolished smallpox epidemics. Yellow fever to all intents and purposes has been eliminated, while malaria has been dealt some weighty blows, indeed we have learned that its abolition is but a matter of money.

The danger of the spreading of diseases such as scarlet fever and diphtheria has been greatly minimized by quarantine regulations and other measures. As Mr. Ley has pointed out, the main means of lowering the death rate and lengthening life have been the improvements which have been made along lines of public hygiene and public health works, as improved water supplies, sanitary sewage disposal, regulation of milk supplies, and improvement in handling foods. Also improved conditions among industrial workers has been another factor in extending the life of the race. However, he is of the opinion and he doubtless is again correct, that the surface has only been scratched as yet in the possibilities of eliminating waste in industry through the prevention of sickness.

Sir David Bruce in his presidential address to the British Association which met in Toronto a few weeks ago, referred to this waste in most emphatic terms. He estimated the loss in Great Britain to this cause to over seven hundred million of dollars and in this country to a much more colossal sum. Stress is to be laid on the point that most of the improvement in the extension of life has been the result of public effort and that the next great step in extending it still further is in the direction of personal hygiene. The time has now come when people must give thought to what each individual can do not only to prolong life but what is more important to keep away sickness which incapacitates and renders life a burden.

The epidemic diseases have been fought and, to a large extent, conquered. The time has come to grapple with the chronic diseases, infant mortality and other generally preventable maladies. Before concluding a perhaps unduly long editorial, some of Sir George Newman's sage remarks on this subject in his annual report will be referred to briefly. He notes that the real health problem of a nation centres rather in the question of sickness and physical impairment, that great burden of suffering which helps to fill the hospitals and asylums, which robs industry of its fullest productivity, and which is the principal cause of physical inefficiency. He emphasizes the point that this general sickness and in-

validity is largely unmeasured and unregistered, though much of it lays the foundation of mortal disease and much of it is preventable. With regard to education in personal and domestic hygiene, in which largely rests the prevention of chronic disease, he insists that it must begin in the elementary schools and should continue through life. It should give particular attention to personal hygiene, nutrition and the right use of foods, and be definitely related to the improvement of national physique and capacity. Also he dwells upon the need for combating disease by means of wholesome environment and healthy living. Mr. Ley and Sir George Newman are both insistent that personal hygiene and environment are leading factors in diminishing sickness and mortality, and the hope is expressed with a considerable amount of confidence that as time goes on and personal and domestic hygiene improve, sickness and invalidity will decrease and the general health will be at a greatly higher standard and consequently life will be longer and healthier.

IODINE AS A THERAPEUTIC AGENT

The great value of iodine as a food and a medicine is now beginning to be recognized. Where iodine is scarce, goitre is abundant and confirmation of the relationship between a lack of iodine and the presence of goitre is continually forthcoming. J. F. McClendon and J. C. Hathaway, of the University of Minnesota, reported recently to the American Medical Association on this point. They analyzed samples of drinking water and food from all parts of the country, and found that where iodine was rare, cases of goitre were numerous. For example, water from Lake Superior near Duluth, Minn., and drinking water from Spokane, Wash., and from Rockford, Ill., contains only one part of iodine to one million parts of water.

Goitre is relatively frequent in the regions in which these places are situated. On the other hand, water from Mexia, Texas, and from Stanford, Cal., where goitre seldom occurs, was found to contain respectively eighteen thousand and ten thousand parts of iodine to the million parts of water. According to the investigations of Drs. McClendon and Hathaway, if the regions in which the proportion of iodine in the water is less than twenty-two parts to the million be charted, the map coincides closely with one in which high percentages of goitre in human beings is found. The result from McCarrison's researches in mountainous districts in India were of somewhat similar character. W. D. Keith, in the *Canadian Medical Association Journal*, April, 1924, stated that British Columbia lent itself to a marked incidence of goitre in man and animals; animals and human beings were sensitive to goitre in Pemberton meadows and it was noted that they did not bring the condition in with them, but acquired it shortly after coming to the valley. In this valley the further up the stream the more pronounced the disease. The only portion of the valley where poor sanitation existed, and where one would think that a contagion might prevail, was in the Indian village, and here no goitre was to be found, either in animals or human beings.

These observations, together with the fact that the incidence of goitre in the valley had disappeared entirely through the use of iodine, forces the conclusion that endemic goitre, as it was found in British Columbia, was an iodine deficiency disease.

THE OLD ORDER

The death of Dr. Dudley A. Sargent comes coincident with the decline and passing of the era of health by exercise in which he was so conspicuous a figure. Not that Sargent was by any means the only apostle of this movement or that his ageing had anything to do with its waning. The whole era began over a hundred years ago and was in its beginning inspired by high ideals of patriotism (or at least for maintaining national integrity) as well as ambition for individual perfection.

The practices in physical training grew out of military drill, and the evolution of elaborate apparatus followed in line, while the theories of the various schools were largely manufactured from the imperfect physiology of the day to fit the ideas and the ideals of the different schools of exercise. The warring systems which arose remind one strongly of the systems in medicine which are not yet fused into one and the benefits believed to result from nicely worked out gymnastic exercises, prescribed in tabloid doses, compare with the magical virtues which it was believed resided in many a drug. Sargent invented some machines for body development which have furnished all around exercise to millions, even if they have not produced all the results anticipated from them.

Sargent belonged to the group which developed pedagogical anthropometry to the highest degree. Besides bringing out the average measurements of college students (toward which mean many have striven, but to which none could voluntarily approximate to any appreciable extent) he pointed out that there are different types of humans—that the athlete who does good weight hurling is built differently from the sprinter and that the pole vaulter and high jumper have their peculiar anatomical attributes—in other words, that athletes are largely born and only polished by coaching.

Sargent lived to be over three score and ten, as did Dr. Hitchcock of Amherst and also Hartvig

Nissen, who passed away a few months since, but others of this school of health by exercise—Baron Posse, Jacob Bolin, Dr. Seaver, and Dr. Gulick—were not so long lived. Exercise is a good thing, but no amount of exercise will overcome faults of heredity, increase in any appreciable degree our resistance to bacteria, or make up for effects of faulty feeding and lack of rest or for injury from disease. Nor can it compensate to any extent for defective vision, deafness, or other bodily defect. Sargent was among those who recognized this to a degree, though the emphasis in his generation was too much on muscular exercise. It is fortunate that in present health work the even more important matters of feeding, rest, the removal of defects and prevention of infection, are being more adequately stressed.

Obituary.

SIR WILLIAM BAYLISS

Sir William Bayliss, whose death in London, announced recently, was perhaps the greatest of contemporary physiologists, and in addition a persistent searcher after knowledge in other realms of science and philosophy. William Maddock Bayliss was born in Wolverhampton in 1860 and was educated privately. He studied medicine but did not complete the medical curriculum. He then came to London and entered as a student at University College in 1881. He here fell under the influence of two teachers—Ray Lankester and Burdon Sanderson. He took the B.Sc. degree in 1882, obtaining the University Scholarship in Zoology. He now returned to medical work, studying physiology first under Burdon Sanderson and when the latter moved to Oxford, under Schafer. When he failed in the second M.B. anatomy examination, he abandoned the idea of a medical degree and devoted himself wholly to physiology. He followed Sanderson to Oxford, and took a first class Natural Science in 1888. He was an omnivorous reader, being of that inquisitive and acquisitive turn of mind which craved universal information. He browsed freely in the pastures of art, literature, science and philosophy and developed that wide range of knowledge and breadth of mind which distinguished him among his fellows.

On his return to London he took up his work again under Schafer at University College. In the early part of 1890 there was begun that colloboration with G. H. Starling which was productive of such fruitful results. Starling, who had been unable to obtain facilities for research at Guy's Hospital, where he was teaching physiology, came to University College, where he soon joined forces with Bayliss, a scientific partnership which lasted up to the time of Bayliss's death. To this collaboration the world is indebted for discoveries relating to the electrical phenomena of the heart, the action of the nerves on the heart, the regulation of the circulation, the movement of the intestine, pancreatic secretion, and the action of hormones.

Bayliss also carried out important researches on vasomotor nerves in conjunction with John Rose Bradford and with L. G. Hill on the circulation of the brain. In 1893 he wrote his classical paper on the depressor nerve and between 1901 and 1908 a series of papers on the origin and mode of action of vasodilator nerves. As said before, his knowledge seemed almost universal and any subject which interested him was a reason for experiment. In the laboratory at Hampstead, he made numerous experiments on various matters merely to satisfy his insatiable curiosity and with no thought of producing a paper or of publishing his results to the outside world. He also read and memorized scientific journals in many languages, his gift for memorizing being remarkable. However, all the knowledge gained from random experiments and somewhat promiscuous reading was not lost. If a knotty point cropped up in the laboratory the rule always was "ask Bayliss."

When Starling was appointed to the Jodrell Chair of Physiology in succession to Schafer, made professor of physiology at Edinburgh University, Bayliss came to the aid of his friend, and first as assistant then as assistant professor and finally as professor of general physiology, took an active part in the teaching work of the department. From 1904 on he published a long array of papers and monographs. These dealt especially with physicochemical problems of physiological importance, and with the mode of the action of enzymes, with occasional excursions into questions concerning dilatation of the bloodvessels.

In 1914 he brought out his book, *Principles of General Physiology,* a veritable landmark in the literature of the subject, and one of the most remarkable scientific books ever put to paper from several points of view. It is not only a valuable scientific work, but at the same time reveals a great deal of the personality of the author. It is in a way an autobiography, or rather the history of a mind and its deeds. From the preface the ordinary reader may obtain a clear conception of the author's views of physiology and of how these views may be brought into practice. The success of this book was immediate and striking. It was recognized by men of science the world over as the embodiment of the living spirit of physiology. In America, so highly is the book esteemed that there are two Bayliss societies, at the meetings of which the members discuss the various chapters of the work. And when through the illness of Bayliss the preparation of a fourth edition was delayed, the task was undertaken gladly by some of the younger physiologists under the editorship of Leonard Hill, in order to testify to the regard and homage in which the writer was held and also to render it easy for all workers in science to have access to a work which had proved already a fruitful source of inspiration and instruction.

During the illness of Starling in 1910-11, and during the war from 1915-19, Bayliss acted as head of the physiological department of University College and his activity and energy knew no intermission. He pursued special researches into the question of war shock and introduced a method of treating this condition by means of gum saline, which was employed at the front with much success.

In 1911 the British Royal Society awarded him its Royal Medal, and in 1919 the same society gave him the Copley Medal, the highest honor in its power to bestow. Honors galore came from foreign academies and from universities and learned societies at home. Wadham College, Oxford, his old college, made him an honorary fellow. He probably worked harder during the last few years of his life than ever before. He was chairman or member of numerous committees, treasurer of the Physiological Society, and in 1923 was appointed editor of *Physiological Abstracts*. In 1893 he married Gertrude Starling, sister of his friend and fellow worker, and was as happy in his home life as in his scientific work.

Bayliss was not only a discoverer and imparter of knowledge, but a source of inspiration. Like all truly great men Bayliss was modest and unassuming.

Christmas Seals.—The National Tuberculosis Association is conducting its seventh annual Christmas seal sale, and has issued an unusually attractive design.

Plague Infected Squirrels.—Plague infected squirrels have been found in San Luis Obispo County, California, according to reports of the United States Public Health Service.

Red Cross Conference.—The American Red Cross held its fourth annual meeting at Washington, D. C., early in October. Dr. Livingston Farrand of Cornell and Dr. Charles P. Emerson of Indiana University, were among the speakers.

Chair of Neurology.—A new chair has been established at the Medical College of Virginia, for neurological surgery, to be held by Dr. C. C. Coleman as professor and Dr. J. G. Lyerly as associate.

Child Health Association Appointment.—Miss Emma Dolfinger has been appointed as director of the health education division of the American Child Health Association, to succeed Miss Sally Lucas Jean.

Texas Medical Examinations.—The Texas State Board of Medical Examiners will examine applicants, at Dallas, November 18th, 19th, and 20th. Application should be made to the secretary, Dr. T. J. Crowe, Mercantile Bank Building, Dallas.

Five o'Clock Lectures at the Postgraduate.—A tentative list has been announced for the five o'clock Wednesday afternoon lectures of the New York Postgraduate Medical School and hospital. These include: Diagnosis and Treatment of Uric Acid Conditions, by Dr. Arthur F. Chace; Infections of the Hand, by Dr. John J. Moorhead; Treatment of Colitis, by Dr. Ludwig Kast; Röentgen Examination of the Gastrointestinal Tract, by Dr. William H. Meyer; Rehabilitation Surgery, by Dr. Fred H. Albee; Toxemias of Pregnancy, by Dr. Harbeck Halsted; Treatment of Essential Hypertension, by Dr. Herman C. Mosenthal; Treatment of Diarrhea in Children, by Dr. Roger H. Dennett; and lectures by Dr. L. E. Lafetra and Dr. Charles Gordon Heyd, titles to be announced.

Medical Centre for New York.—The Board of Managers of the Presbyterian Hospital, New York, has announced its decision to erect a building jointly with the College of Physicians and Surgeons of Columbia University, at Broadway and 168th Street (the old American League Baseball Park.) Plans for this cooperation were tentatively made about three years ago. The Presbyterian Hospital section will cost $7,000,000, of which $2,500,000 is available, leaving $4,500,000 still to be raised. A campaign to raise this fund will shortly be started,—the first public appeal ever made by this hospital. The section of the building to be occupied by the College of Physicians and Surgeons is to cost $3,000,000, which has been subscribed. Besides wards accommodating over six hundred patients, there will be a private pavilion for one hundred and twenty-five patients. Facilities for research are also to be provided.

New University Hospital.—The hospital for the medical school of the University of Wisconsin, known as the "State of Wisconsin General Hospital," is now being opened for patients. Its capacity is over three hundred beds.

Health Demonstration.—The Milbank Memorial Fund has announced that it has selected for purposes of an intensive health demonstration over a period of years, the district bounded by Fourteenth and Sixty-fourth streets, and Fourth avenue and the East River.

Centennial of Jefferson Medical College.—Exercises were held on September 23d, in the clinical amphitheatre of the new hospital building of the Jefferson Medical College, Philadelphia, to mark the opening of its hundredth year. Dr. Bowman C. Crowell gave an address on A Century of Progress.

Census of the Blind.—The New York State Commission for the Blind states that its census shows 8,001 blind persons in the state, of whom 3,728 live in New York City. The commission also states that the number of persons with serious visual defects is much larger than the number who are blind.

Sickness Index.—The United Hospital Fund, through its Hospital Information Bureau, is planning a study of the amounts and kinds of illness given hospital treatment. Six large hospitals, members of the fund, have agreed to furnish statistical information of this type, and it is believed that present hospital facilities can be better adjusted, and future facilities planned to meet their exact requirements.

Cornerstone of Rush Medical College.—The cornerstone of Rush Medical College, laid November 20, 1875, has been removed due to wrecking operations. The box was opened by the Grand Master of the Masonic Lodge of Illinois, at a ceremony attended by prominent Chicago people. It contained copies of the *Chicago Medical Journal* of 1867, copies of Chicago newspapers, the city directory, tourists' guide for 1875, pictures of the faculty of the college and the valedictorian address of 1871, also the college charter.

Coming Meetings of Societies.—The New York State Association of Public Health Laboratories will hold a mid-year meeting November 5th, at the State Laboratory in Albany.

The Medical Society of Virginia is meeting from October 14th to 17th, at Staunton, Virginia. Dr. A. J. Ochsner, of Chicago, Dr. John O. Polak, of Brooklyn, and Dr. Daniel A. Orth, of Chicago, have been invited to speak.

The National Social Hygiene conference will be held at Cincinnati, November 19th to 22nd, marking the tenth anniversary of the society. Dr. Hugh S. Cumming, Mr. Lee K. Frankel, and Mrs. Clive Neville-Rolfe, general secretary of the National Council for Combating Venereal Disease, London, are among the speakers.

The American Public Health Association will hold its fifty-third annual meeting in Detroit, October 20th to 23rd. Dr. T. Madsen, chairman of the health section of the League of Nations, will be one of the speakers. Dr. R. M. Olin, health commissioner of Michigan, is chairman of the local committee of arrangements.

Personals.—Dr. I. M. Kolthoff, a noted chemist of the University of Utrecht, has recently been in New York.

Professor Costa Forstell, a Swedish röntgenologist who has been in this country, has returned to Sweden.

Dr. W. B. Hardy, a British chemist and biologist, has recently been in New York.

Dr. Ethel D. Humphrys has been appointed acting city manager of health and charity of Denver, Colorado, succeeding George A. Collins, who has become superintendent of the new University of Colorado hospital.

Dr. William R. Davidson of Evansville, Indiana, has been appointed president of the council of the Indiana State Medical Association.

Dr. John Albert Key, of Baltimore, is to have charge of research work at the Shriner Hospital for Crippled Children, at St. Louis.

Dr. Robert J. Wilson has been honored by a gift of an illuminated autographed volume by his fellow workers at the bureau of hospitals, New York City department of health, on the occasion of his retirement after twenty-eight years of service.

Dr. Edward Hoening has been appointed associate gynecologist to the Jewish Memorial Hospital of New York.

Foreign Correspondence

PARIS LETTER

(*From our own correspondent*)

PARIS, *September 6, 1924.*

A GENERAL ONSLAUGHT

For some time past, there has been a tendency on the part of the French press, or at any rate on the part of certain organs thereof, to imply that all is not for the best in the French medical world. With the coming of summer, and the consequent dearth of news, the tendency became more marked, until it developed into a regular offensive under the leadership of the *Oeuvre,* a leading morning paper of strong Radical-Socialist views. The gravamen of the charge is that too many physicians and surgeons in this country at the present moment are of the get rich quick kind, that they give precedence to money before patient, and that, generally speaking, there is a slackening of professional conscience. As is customary in all campaigns, there is a foundation of fact in these sweeping indictments and a very exaggerated superstructure. On final analysis, the most serious arraignment against the profession as a whole relates to dichotomy, which is the learned word used here to signify splitting fifty-fifty between surgeon and attending physician. And when you come to rock bottom the World War is to blame once again.

AN OVERCROWDED PROFESSION

The fact is that there are in France too many physicians and too many surgeons, both native Frenchmen and foreigners. Right here it is as well to open a parenthesis. There are two categories of foreign practitioners. There is nothing to say against the American and English doctors in France, whose number has increased simply in proportion to the growth of the colonies of residents from the United States and from Great Britain. Their *clientèle,* on the whole, is made up of their fellow countrymen and countrywomen. They are admittedly most honorable practitioners, and there is nothing but praise for the American Hospital at Neuilly-sur-Seine as well as for the Hertford British Hospital. The American and British physicians and surgeons in France are quite content to remain American or British physicians or surgeons. Indeed, it is their pride thus to remain. Not so with other nationalities. More than ever do the medical schools of Nancy and Montpellier include on their rolls the names of foreign students seeking the French degree. The former is favored by men from Near Eastern countries and the latter by Turkish and Egyptian would-be doctors. This was already the case before the war. Many a brass plate in Cairo bore the indication "M.D. of Montpellier University."

COMPETITION WITH THE FRENCH

Many of these men become naturalized French citizens. Some return home, but a large proportion remains in this country, to practise in the large cities. Already the number of French native born practitioners is too large; the foreign element comes to swell an overcrowded profession. Moreover, it is a peculiar psychological fact that many patients will be attracted by a foreign name who would hesitate to believe in the superlative qualifications of a fellow countryman. In these conditions, there is little love lost between the French physician and his foreign confrère whom he is inclined to look upon as an interloper. In most instances both classes served in the war; the former was drafted and the latter volunteered. After the armistice the foreign category returned to civilian practice, of necessity, the Army Medical Service not being normally open to them. The native born physicians also left the army because the financial inducements were insufficient. Both doffed the uniform and promptly started a war of competition for practices.

OPPORTUNITIES FOR FRAUD

The struggle, it must be admitted, was not always honest. Moreover, postwar conditions lent themselves to fraud. On the side of the combatants, there was State payment to doctors who attended the thousands of maimed and gassed. So pressing was the need of medical attention for all such that it was not possible for government departments immediately to devise adequate regulations. As a consequence physicians and pharmacists in some cases—the most flagrant instance led to wholesale prosecutions at Marseilles—leagued themselves for the purpose of extracting unjustified fees from the State. On the side of the noncombatants there was the application of laws for the insurance of employees against accidents. In this instance also, the same reason—insufficient time for the elaboration of comprehensive regulations—the door was left open for abuse. In this connection, too, prosecutions have been numerous.

TEMPTATION IS STRONG

Not that the black sheep are numerous by any means, but temptation is strong, and there are always feeble brethren who fall by the wayside. Few start out with bad inclinations. The majority succeed in resisting. Yet too many succumb to the wiles of dichotomy. The young doctor, animated by the best of intentions, finds that a brass plate at his door is not sufficient to attract patients. When the first one finds his way to his consulting room the temptation is great to magnify his ailment. With a clear conscience it is possible to argue that no diagnosis is infallible. The symptoms generally may point to a benign malady, yet there is a minor, very minor indication of the possible presence of something more serious. The more serious may become most serious if not attended to. A slight operation tomorrow may avoid a grave operation at a later date. And surgeons split fees. It takes character to stop right here and to prescribe liniment instead of calling in a specialist.

SOME OF THE CHARGES

Laymen, particularly of the journalistic persuasion, assert that too many young physicians have not the force of character necessary to repulse temp-

lation. They declare that patients are inveigled into expensive consultations and operations when there is no necessity therefor; that long treatments are prescribed in order to obtain fees from patients who could be cured in relatively short time; that the simplest of operations is magnified, for the same purpose; that, in a word, too many physicians and surgeons are out to make money.

As usual, while there is no smoke without fire, there are too many critics prepared to dump down armfuls of damp straw on the slightest blaze. That there are black sheep in the profession is not denied. There are in all professions. That the war has led to the increase of such black sheep is also admitted, but in spite of all this the proportion of chaff to grain is very small, and the black sheep in a flock are counted on the fingers of one hand. On the other side of the account must be set the ever increasing number of doctors who devote themselves to the public good, frequently for no fee at all; the numerous leaders of the profession who give their services free of charge in hospitals and poor-houses, and the hundreds of humble practitioners who for a small income give their whole time, much of their health and too frequently their lives also for the sake of those who consult them. In a word, the attack turns out to be chiefly a newspaper scare.

TISSUE GROWING

As a result of experiments which have lasted several years on the cultivation of animal tissues outside the organism, M. Champy, a well known physiologist of the Collège de France, has obtained results which lead to the belief that the mystery of the origin of cancer is on the point of solution.

M. Champy's experiments are a continuation of those of Professor Carrel in the cultivation of living tissue and the indefinite multiplication of cells detached from the body. It was thought after Professor Carrel's early investigations that the cells went on reproducing their own species—in other words, that fragments of the kidneys or of the thyroid gland reproduced renal or thyroid cells. According to M. Champy this is not the case. Instead the cells become modified, or, in the physiologist's own words, they "differentiate" and form cells which possess all the properties of cancerous cells. M. Champy thinks that this disproves the theory held for a long time that cancer was due to a microbe never yet isolated, and goes to show that the disease is engendered by the organism itself as a result of functional disequilibrium.

REPORTABLE DISEASES

The *Journal Officiel* of the French Government recently published a list of diseases which the doctor is obliged to report to the Health Department, as follows: Typhoid fever, exanthemic typhus, variola or varioloid, scarlet fever, measles, diphtheria, suette miliaire, cholera and *maladies choleriforme,* pest, yellow fever, dysentery, puerperal infection and ophthalmia neonatorum, cerebrospinal meningitis, acute poliomyelitis, trachoma, undulant fever; to which is added the following list, the reporting of which remains to the discretion of the medical attendant: Tuberculosis, whooping cough, influenza, pneumonia and bronchopneumonia, erysipelas, leprosy and favus or ringworm.

GENEVA LETTER

(From our own correspondent)

GENEVA, *September 1, 1924.*

PHLEGMON OF CAROTID

Richard reported the case of a patient operated on for a phlegmon of the carotid and towards the end of the operation developed syncope. After several various attempts had been made to deal with the syncope, all of which were fruitless and consumed altogether twelve to fifteen minutes, Richard gave an intracardiac injection of two c.c. of adrenalin solution 1/1000. The heart beats, although weak, reappeared and then ceased. A second injection into the heart caused the beats to recur, but this time they were strong and regular. Unfortunately respiratory syncope persisted and the patient died. Although this case was only a partial success, nevertheless it demonstrates the favorable action of injections of adrenalin into the heart when very urgent indications for this procedure prevail, and it would seem indicated in future cases of severe operative syncope to resort to it without loss of time as occurred in the case reported.

PAINFUL SACRALIZATION

In a recent thesis (Paris, 1923), Meynadier has presented a very complete study of painful sacralization of the fifth lumbar vertebra. This condition may occasionally coincide with a posterior spina bifida. The pathogenesis of this painful anatomical process is probably not due to a single factor, because in the more serious cases the fifth lumbar root is involved. The symptomatology of painful sacralization is varied and rich, although Bertolotti's syndrome still possesses a relative value.

Before making a diagnosis of painful sacralization those affections which may simulate it must be ruled out, and in this respect radiography will greatly aid in making a differential diagnosis, but it must be carried out with a strictly rigorous technic. Only cases of authentic sacralization are to be operated on, with absence of associated lesions other than a typical and complete scoliosis offering a serious symptomatology. It is to be remembered that certain very marked sacralizations with partial fusion of the sacral wing—and these are among the most severe cases—may not be operable. In general, when properly selected, the operative results are distinctly favorable.

SEMIOLOGY OF NEOPLASMS

I would call attention to the recent studies persued by Guillain on the semiology of neoplasms of the corpus callosum. Tumors of the splenium of the corpus collosum make themselves known by symptoms of intracranial hypertension with headache, vomiting and occasionally papillary stasis, also early mental disturbances, sometimes resembling those of general paralysis, consisting of amnesia, peculiar acts, emotional indifference, disorientation, torpor interrupted by periods of agitation, absence of systematized delirium, but with mental disturbances ending in a true state of dementia. Motor disturbances, apparently due to extension of the neoplasm to the pyramidal fibres or the central gray nuclei, also are met with, and sometimes phenomena of

apraxia. Aphasia never occurs, and rarely is there paralysis of the basal cranial nerves.

Study of the cerebrospinal fluid, especially the negative Wassermann reaction, and colloidal benzoin reaction, allow one to eliminate the diagnosis of general paralysis and syphilis of the neuraxis. It is preferable not to resort to the socalled therapeutic tests with salvarsan or other antisyphilitic medication.

LATIN AMERICA LETTER

(*From our own correspondent*)

Balboa Heights, Canal Zone, *August 4, 1924.*

MEDICAL INSPECTION AT CALLAO, PERU, DISCONTINUED BY UNITED STATES

Doctor Castro Gutierrez, acting assistant surgeon, United States Public Health Service, has been relieved from duty at the U. S. Consulate in Callao. The service of medical supervision by the United States has been temporarily discontinued. All cargo from Callao destined to the Canal ports and to those in the United States must be fumigated for the destruction of rats. This supervision of fumigation will be continued by the local authorities at Callao and Paita and will be certified to by the United States consuls at these ports. The last case of human plague in Paita occurred during the month of March, 1924.

HEALTH OFFICER OF PANAMA VISITS EUROPE

Dr. Henry Goldthwaite, health officer of Panama City, accompanied by Mrs. Goldthwaite, has left the Isthmus for a four months' sojourn in Europe. Doctor Goldthwaite is taking a well earned leave of absence and will visit the principal cities in southern Europe. Later he and Mrs. Goldthwaite will visit Admiral Mark Bristol, American High Commissioner of Constantinople.

PANAMA'S CRIPPLED CHILDREN TO RECEIVE AID

Major E. A. Bocock, M.C., U. S. A., superintendent of the Santo Tomas Hospital of Panama City, in a recent address before the Rotary Club of that city, made a plea for a drive by the club to obtain the names and addresses of the crippled children of the Republic. It is his intention to reach these unfortunate children and have them brought to the hospital for surgical relief. This will be done without expense to the parents. Major Bocock has been superintendent of the hospital since July, 1919, and through his efficient administration has gained the confidence and admiration of the government officials of Panama, especially of His Excellency President Porras. He was to have been relieved from duty in July for the purpose of a detail to the Army Medical School at Washington, D. C., but on the request of the Panama Government his orders were revoked, in order that he may continue in the service of the Santo Tomas Hospital. An entirely new hospital plant is being constructed which will undoubtedly be the best appointed institution in South America. It will be ready for occupancy about October 1st.

FINAL VERDICT ON PANAMA'S WHITE INDIANS

The three "white" Indian children whom Richard O. Marsh took from Panama have been proclaimed by medical and other experts in the States to be none other than albinos. Mr. Marsh took these children to the States and presented them before a group of scientists for the purpose of substantiating his claim that he had discovered a new race—a tribe of White Indians. The opinion of the experts of the United States coincides with that of the medical fraternity of the Canal Zone and Panama. The discovery of albinism among Indians of the Darien region is not a new one. It is claimed that Columbus observed white Indians and that they were later seen by Balboa and many other explorers of olden and modern times. An account by the explorer Wafer who penetrated into the Darien of Panama in 1681 reads as follows: "They are white and are of both sexes; yet there are few of them in comparison to the copper colored. Their skins are not of such a white as those of fair people among Europeans, yet some tincture of a bluish or sanguine complexion. But 'tis rather a milk white, much like that of a white horse." It is understood that Mr. Marsh intends to return his group of Indians to their native country in a very short time.

AVOIDABLE TRAFFIC ACCIDENTS IN THE CANAL ZONE

During the fiscal year ending June 30, 1924, there were 280 traffic accidents on the Canal Zone or an average of twenty-three a month, resulting in the death of six persons and the injury of fifty others.

The classification of the causes shows that practically all of the accidents were avoidable and were due to careless and reckless operation of vehicles. The causes of the accidents were as follows: Intoxicated drivers, five; reckless driving, 194; careless driving, fifty-seven; inexperienced drivers, three; careless bicyclists, two; defective roads, two; defective machines, three; intoxicated pedestrians, one; irresponsible children, one. Of the 280 accidents, collisions occurred in 258. Damage to property resulted in 259. Thirty-two persons in vehicles were injured; eighteen pedestrians were injured and six deaths resulted. Of 418 vehicles figuring in the accidents 154 were driven by their owners and 274 were driven by someone other than the owner.

TYPHOID FEVER IN HAVANA

It is reported that typhoid fever is prevailing in epidemic form in Havana. According to Commander R. E. Old, Medical Officer of the *Rochester*, who has just arrived from Cuba, over four hundred cases have been reported in the city of Havana to date. There has been an average of eight deaths per day. It seems probable that this is a water borne epidemic. The available supply of safe drinking water is not large enough to meet the demands of the city. It is also claimed that ice is made from untreated water and is a constant source of danger.

There is also reported a smaller epidemic in Costa Rica, especially in San Jose and Cartago and their outlying districts. The *Rochester* has just completed a cruise which included a number of the ports of the Caribbean Sea, and an interesting report of the sanitary conditions has been written by the medical officers of the ship.

MEDICAL RECIPROCITY IN LATIN AMERICA IS URGED

The necessity of increasing the efficiency of Pan-American medical and public health work by means

f medical reciprocity, and the establishment in Pan-ma of a Pan-American Examination Board or other uthorized agency was urged in resolutions passed y the International Conference on Health Problems i Tropical America, held recently in Kingston, Ja-maica. Copies of resolutions passed were brought the Isthmus yesterday by returning delegates. he resolutions are as follows:

In view of the increasing realization of the fact that dis-se has no national boundaries and that it is in the interest f every country to secure a high standard of work in cura-ve and preventive medicine, the International Conference on ealth Problems in Tropical America, which has been visit-g Jamaica and various Central American republics, is esirous before it dissolves to set out recommendations, the loption of which, would, in their judgment, greatly increase ie efficiency of Pan-American medical and public health ork.

As a means to this end, they are impressed with the im-ortance attaching to extension of facilities for interchange medical work between the different states concerned.

The following statement indicates in part the existing posi-on as to medical reciprocity between American republics. Guatemala, San Salvador, Honduras, Nicaragua and Costa ica have formed a Central American medical reciprocity. mong these republics a large amount of medical reciprocity ready exists.

Similarly in South America there is more or less medical ciprocity between Colombia, Venezuela, Ecuador, Peru id Bolivia.

Some further action in the same direction was initiated at Pan-American Congress held in Uruguay in 1910.

Resolution 1: In the opinion of this conference action in ie direction of further reciprocity could most appropriately taken by the Pan-American Union.

Resolution 2: The conference is of the opinion that in any ange that takes place reciprocal practice between republics ould be subject to the condition that the physicians ex-mined reach an acceptable standard of training and ex-nination.

Resolution 3: The conference is of the opinion that at ie earliest practicable moment it is desirable to establish some central point, or points, a Pan-American Examina-on Board or other authorized agency, enforcing a high andard. Panama being recommended for the first centre r such a Board because of its accessibility.

Resolution 4: The conference is of opinion that any aduate of a medical school, wherever situated, enforcing ch a standard as is indicated by Class A of the American edical Association, who also holds a diploma from the amining body named above, should be accepted for licen-re for practice in any of the signatory republics.

Resolution 5: The conference is also of opinion that as immediate step towards wider medical reciprocity in an-America the National Board of Medical Examiners of e United States should be asked to initiate at certain ntres accessible to Latin America, examinations in Spanish in the official language of any country, in addition to the esent examinations in English.

The conference recommends that a copy of this memo-ndum should be sent to the Pan-American Union, with e request that the Union should communicate its con-nts to the appropriate Government department of each of e republic concerned, to the Rector of the National Uni-rsity of each republic where such an institution exists, the National Board of Medical Examiners of the United ates, and to others interested.

EDICAL ASSOCIATION OF THE ISTHMIAN CANAL ZONE

The 211th meeting of the Medical Association of ie Isthmian Canal Zone was held at the Ancon Hos-tal on July 15, 1924. The program included the llowing papers: Some Observations of Field ervice in Panama, by Captain E. H. Perry; The orto Rican Soldier from a Medical Standpoint, by ajor Clarke Blanco; Duties of a Flight Surgeon, Captain A. W. Smith. These interesting papers were the subject of much discussion by members of the association.

DEADLY FUMES IN THE COLOMBIA'S HOLD

Four negro laborers of the Canal were recently killed by gases emanating from decomposing cargo in the hold of the steamship *Colombia*. These gases, largely hydrogen disulphide, were evolved from rotting beans and green coffee. The *Colombia* had been on the rocks for the past three weeks off Cano Island in the Pacific and was brought to Balboa for dry docking. Six men were in the hold at the time of the accident, but two managed to get out before being fatally overcome. An expert diver was then lowered into the hold and succeeded in getting ropes upon the men. All were dead when brought to the deck of the ship. The diver was also overcome but was hauled out and given artificial respiration.

MALARIA ON THE ISTHMUS

It is interesting to note that in spite of mosquito eradication work and constant extension of sanitated areas of the Canal Zone the malarial incidence has been on a steady increase during the past five years, according to records of the Health Department. Three factors contribute to this increase: The opening of land for agricultural purposes; extensive dredging in Gaillard Cut, unavoidable night work; the military population. The high rate among the military population, which greatly exceeds the combined rate for all others, is due largely to the necessity of carrying on practice maneuvres in unsanitated areas and to the enlisted man's propensity for wandering about the country in all seasons and at all hours, as well as to the location of some of the army posts and naval bases, least favorable for sanitating.

EMISSARY OF THE AMERICAN COLLEGE OF SURGEONS

Dr. Edward I. Salisbury, associate director of the American College of Surgeons, director of Inter-American Affairs, is spending a few days on the Isthmus en route from Peru to Jamaica, where he will attend the Conference on Tropical Medicine in Kingston. Dr. Salisbury is engaged in a survey of the hospitals of Central and South America with a view to their ultimate standardization on a basis similar to that being carried into effect in the United States and Canada. He is at present seeking a solution to their most urgent need, the establishment of a higher system of nursing.

YELLOW FEVER INVESTIGATIONS IN SAN SALVADOR

Dr. C. P. Knight, Chief Quarantine Officer of the Panama Canal, has returned to the Isthmus after completing an investigation of reported yellow fever in San Salvador, the capital of the Republic of El Salvador. Dr. Knight arrived in San Salvador on July 3, 1924, where a conference was immediately held with the President of the Republic and the Chief of the Health Depatrment. A thorough investigation was then inaugurated. During the month of June there were reported two deaths and seven cases of a disease which simulated yellow fever in many particulars, but after a thorough investigation, grave doubt exists as to the actual presence of the dread disease. No new cases occurred during the investigation, but further studies are being carried on and will be the subject of future correspondence.

Book Reviews

PSYCHOANALYSIS

Essays in Applied Psychoanalysis. By Ernest Jones, M.D. President of the International Psychoanalytical Association and of the British Psychoanalytical Society. The International Psychoanalytical Library, No. 5. London and Vienna: The International Psychoanalytical Press, 1923. Pp. 454.

Psychoanalysis and Æsthetics. By Charles Baudouin. Translated from the French by Eden and Cedar Paul. New York: Dodd, Mead and Company, 1924. Pp. 328.

These two volumes invite comparison through their similarity of interest and yet through the contrast in the attitudes of their authors. There is a difference, also, to some extent, in the nature of their subject matter. The latter book is written by an author first of all esthetically attuned. His translators, in their excellent introduction, have styled him both a psychologist and a poet. Psychoanalysis has illuminated his way into a more penetrating understanding of the inner life of the poet he studies and of the significance of this poet's writings. Yet there is an esthetic check upon making the interpretation of these as clear and bold as it might be. Jones, on the other hand, moves more familiarly among the facts which represent the findings of psychoanalysis and points them out with incisive strokes. Dealing with the crudely concrete elements which underlie poetry, superstition and religion, he, nevertheless, treats them with a delicacy born of the recognition of their fundamental and undeniable significance in the foundations of all cultural products. His is, therefore, a bolder frankness, but none the less truly esthetic.

Baudouin has not been unmindful of these elements which seem at first sight contradictory to the very thought of esthetics. He has not dared, however, to discover and bring them into definite expression as Jones never hesitates to do. Baudouin acknowledges that he avoids that widespread sexual interpretation which Freud attributes to the matter under repression in the unconscious. He willingly admits the Œdipus complex functioning in the life of Verhaeren, the poet whom he studies, and finding expression in his work. The stumbling block seems to be in the more precise nature of the elements of infantile sexuality bound with the Œdipus complex. And it is just in the revelation of these that Jones renders his signal service in the investigation of his material.

Baudouin comes nearer to this than he discerns, when he proceeds to the actual analysis of many of Verhaeren's expressions. In the poet's own lines, which Baudouin has introduced generously into his work, the reader finds more in the symbolism than his expounder has dared to see. Baudouin frequently stops at a question, which might be at least further pressed toward its answer. Often there is generalization, when the fullness of the poet's symbol suggests still deeper concrete analysis. This more concrete detail of the unconscious would be illuminating alike for the earlier conflict through which the poet passes and for the victory which he achieves. At times, Baudouin touches more definitely upon this detail, but too often he has missed elements which the poet's symbols thrust vividly before us. Baudouin has rendered a positive service, however, in leading forward in the direction of this more fundamental interpretation of literature. He has given a specially clear analysis of the Œdipus theme in the poet's work, as found in his lyric dramas, the "Œdipus trilogy," which represented one period of his creative work. Baudouin has thus contributed, by his analytical insight and by the clarity of his intellectual thought, both to psychoanalytical psychology and to esthetics. He lays especial emphasis upon the service of the symbol to the poet himself and finds in the study of this the record of the conflict through which the poet finally attains a higher stage of psychic evolution. Baudouin defines at length the symbol and its use in the light of this, its function in psychic evolution. He discusses the condensations, displacements, transference—not all in the strictly Freudian sense—which the symbol represents. Through these, he shows, Verhaeren expressed the conflict of his inner life, his regressive introversion, and finally the winning of a healthy extroverted attitude toward the external world.

Jones has presented us with a series of studies which had formerly been printed separately, most of them not in English. Together they form a comprehensive investigation into the unconscious motives that influence human lives. They reveal concrete elements, repressed and forgotten by consciousness, but possible of rediscovery in the most trivial or the most cherished beliefs of mankind. He has devoted some of his essays to the study of literary subjects. His investigation of Hamlet's psychic situation, a puzzle to critics throughout the centuries, may certainly rank as a classic among all former attempts to explain it. Jones reviews some of these former attempts to resolve the mystery which Shakespeare created, and then proves how much illumination psychoanalysis is able to throw upon the obscurity.

Jones gives also a brief study of the unconscious motivation of "dying together," using as his material the strange death of the poet von Kleist and a mysterious occurrence at Niagara Falls. He gives us insight into Andrea del Sarto and Louis Bonaparte in their peculiar psychic situations. He discusses the "God complex" which resides in man. He submits to a far more comprehensive study the symbolic significance which has always surrounded salt, but deepens and extends the examination of unconscious valuations and conceptions in his still more elaborate study of the Madonna's conception. This is a fearless revelation, not alone of those elements of the unconscious which our other psychoanalytically inclined esthetic writer finds it hard to accept. It is a fundamental searching into the basic material out of which the most spiritualized religious conceptions are built. And this is to find the extreme infantile character of this material as well as the infantile nature of the exalted psychic structures which have been elaborated both to satisfy and to conceal the infantile concepts. Yet to know these

things as Jones searches them out and sets them forth, is not to debase the higher product. It is only to aid in the "transformation of religion" to something more real, to aid in the "supersession of the pleasure principles by the reality principle." Further brief essays, one upon religious belief, two sociopolitical, further advance this latter aim.

NEUROLOGY

Diagnosis of Nervous Diseases. By Sir James Purves-Stewart, K.C.M.G., C.B., M.D.Edin., F.R.C.P. Sixth edition, revised. New York: E. B. Treat and Company; London: Edward Arnold and Company, 1924. Pp. 648.

Lehrbuch der Nervenkrankheiten. Für Studierende und praktische Arzte, in 30 Verlesungen. Von Robert Bing. Dritter, vermehrte und umgearbeitete Auflage. Mit 184 zum Teil mehrfarbigen Abbildungen. Berlin und Wien: Urban und Schwarzenburg, 1924. Pp. 709.

So long as Purves-Stewart remains in the realm of organic neurology we can follow him and respect his carefully compiled textbook. But when he attempts to wallow about in the functional field of the psychoneuroses his efforts are pathetic. The reader who desires a convenient textbook on neurology and does not feel the need of information in regard to the functional nervous disturbances will do well to depend on Purves-Stewart. But the book as a whole, in the analogy of a team seems to resemble a good horse hitched to the side of a decrepit donkey.

Most of what has been said of Purves-Stewart may be repeated about Bing. No more careful worker than Bing could be found in the organic field. In addition, in this last edition of his book he gives an excellent résumé of the findings in the hysterical psychoneurotic group. However, when it comes to accepting his halfbaked idea on the etiology and treatment of the psychoneuroses, a line must be drawn.

MENTAL DISEASES IN SWEDISH ARMY AND NAVY

Om Psykisk Undermalighet Och Sinnessjukdomar. Bland Svenska Arméns Och Marinens Manskap. Av Harald Fröderström. Stockholm: P. A. Norstedt & Söner, 1913. Pp. 168.

The author in this thesis which he presented for promotion to the degree of Med. Dr. at the Royal Medical College, Stockholm, May 6, 1913, deals with psychic abnormalities and mental disease in the Swedish Army and Navy. He reviews the statistics regarding mental abnormalities in many European countries as well as Sweden, and finds that these have been uniformly on the increase during the last two or three decades. Some observers attribute the fact to the social, political, and cultural conditions of modern civilization, which place higher requirements upon the intellectual capacity, especially in large cities and industrial centres, while others ascribe the upturn in the statistical curve of psychomorbidity from one to nearly three per cent. in Sweden, to the fact that modern institutions with their increased facilities attract and harbor many mental cases that previously were cared for privately.

As to the relation of war to psychic disturbances, it has been definitely shown by statistics—what would seem to be a natural inference—that the ratio of these is increased, even doubled, not only among the combatants but also among the afflicted civilian population of belligerent countries.

In his survey of the psychically abnormal contingent that enters into the personnel of the Swedish army and navy, the author groups these incompetents under two heads, the mentally deficient and the mentally diseased, the latter showing a concrete symptomatic entity with manifest disturbance of cerebral function. Under the former he includes idiocy, imbecility, debility (psychophysical) and depravity. Under the latter appear infantile psychoses, psychoses of puberty, schizophrenia, manic depressive states, transitory psychoses and dromomania. He cites a long list of case histories of his own and other observers. From comparative statistical studies the inference is drawn that Sweden in case of war would count on a psychomorbidity of two per cent. of the personnel of its military forces.

The author urges the need of a more effective administration, of competent psychiatrists and greater facilities in handling the mentally deficient, not only in the interests of these latter, but in the interests of military discipline and efficiency.

MENTAL DISEASES

Mental Diseases. A Public Health Problem. By James V. May, M.D. Boston: Richard G. Badger, 1924.

The most useful purpose of this book has been accomplished through the combined approach to the problem of mental disorders, namely, the psychological, economic and social, as well as a presentation of the organic conditions accompanying mental disorders. This has been done with marked success, no phase being unduly overemphasized, and a unity preserved which is gratifying. The work will fill a distinct niche in the field of psychopathology and be of service to the social worker, physician, jurist, publicist, and educator. It is fortunate indeed that a book of such wide influence should be so sensibly written and in so lucid a manner.

ORTHOPEDIC SURGERY

Selected Essays on Orthopedic Surgery. From the writings of Newton Melman Shaffer, M.D., F.A.C.S. Illustrated. New York and London: G. P. Putnam's Sons, 1923.

In reviewing this book one is struck by the marked similarity to the present day understanding of the diseases discussed by the author. In one or two details only is there any marked difference. For example, in the treatment of the tuberculous abscess, noninterference is advised irrespective of the fact that the abscess may rupture any moment. It is hard to understand how secondary infection can be eliminated when the abscess is allowed to rupture spontaneously, in preference to a paracentesis, which he forbids because secondary infection may be introduced that way.

His discussion of hip joint disease is a pleasure to read. The symptoms are thoroughly analyzed and discussed. The treatment, especially in the early stage, when flexion deformity is present, is given an undue amount of attention. In our opinion this is the only book which has satisfied our idea of the importance it really deserves.

Irrespective of the fact that the nomenclature of the essay on nondeforming club feet is not exactly correct, it brings to light a series of conditions which could otherwise not be emphasized were they to be placed in their real respective diseases. Much atten-

tion is paid to the mechanical treatment of club feet, a procedure which is not much in vogue today.

His emphasis on the short tendo achilles and its rôle in the production of flat foot deserves particular attention, as its importance in the treatment has only been recognized for a comparatively short time. The abduction treatment for fracture of the neck of the femur is being hailed today as a specific, when the origin of this procedure was introduced many years ago by Shaffer. The article on the stretching of the ligamentum patellæ is quite interesting. In fact little mention of it is made in any other orthopedic book. Its play in the pathology of internal derangements of the knee joint has been brought out clearly here.

It must be gratifying to Shaffer in his perusal of other orthopedic books to see how little has been added to his essays. When we realize that in the author's time orthopedics was in its embryonic stage compared to the present time, then no greater tribute can be paid to him than to say that the book is worth while reading to have a real conception of modern orthopedics.

PUBLIC HEALTH SERVICE ACTIVITIES

Annual Report of the Surgeon General of the Public Health Service of the United States for the Fiscal Year 1923. Washington: Government Printing Office, 1923. Pp. 316.

This report for the year 1923 is unusually full and treats in considerable detail the work of the various divisions of the Public Health Service. The statement is made that the sanitary reports of the country as a whole show that health conditions throughout the United States have continued as satisfactory as in recent years, in spite of the widespread conditions of certain communicable diseases abroad. This lack of disease conditions is probably due to the increasing interest on the part of the public in health improvements, and to the enforcement of the international sanitary agreements and the maintenance of the national quarantine system, permitting no cases of the major quarantinable diseases to gain access to this country during the year. An outbreak of yellow fever in Colombia and other localities and a high mosquito index in various ports of tropical America, made it necessary to impose somewhat more stringent quarantine restrictions than in previous years. The recognition of the Government of Mexico, however, and the improvements in sanitation contemplated for Mexican ports may make possible the removal of some of these restrictions.

Both human and rodent plague appear to have been eradicated in the United States, except in the case of infected ground squirrels in California, and all antiplague measures, except in that State, have been discontinued. Only one human case of plague occurred during the year. Through the active work of the maritime quarantine stations at domestic ports, and of the medical officers stationed at foreign ports, much improvement has resulted in health conditions of immigrants at domestic ports.

A great advance has been made, according to the report, in the hospital standards of the Public Health Service, so that now the service compares favorably with that of the civilian hospitals, while there has been a reduction in the cost. The marine hospitals are now provided with a trained female nursing service, physiotherapy aides, dietitians, and consultants in the various specialties of medicine and surgery.

The studies and demonstrations in rural sanitation have shown that the fundamental need throughout the rural districts of the United States is the establishment of efficient local whole time health service through which the measures necessary for the protection and promotion of the public health may be conducted in logical sequence and in proper relation to each other. Promotion of general health and prosperity will be best served by aiding in establishing, developing, strengthening and maintaining State and local health departments.

Research has been made along many lines, among which may be mentioned the Paris green method for control of mosquito breeding, and the creosote method for repelling mosquitoes in dwellings which cannot be screened, both of which have been developed and proved of value in antimalarial work; a real contribution to the treatment of neurosyphilis and the prevention of mental disease due to it has been effected by designating the forms of arsenic most valuable in treatment.

Among recommendations made in the report are that the studies and demonstrations in rural districts be superseded by a plan of work to be conducted with the States on a cooperative basis, thus advancing immeasurably the cause of public health and eliminating much needless overhead; adequate funds are solicited for carrying on the national quarantine work; for additional hospital facilities, including repairs to old buildings, new hospitals, and housing for increased medical personnel; for the control of venereal diseases; and for adequate pay of the lower grades of commissioned officers. Legislation providing for larger editions of publications used in public health education, and for shortening the term of service of assistant surgeons is also recommended.

HEMORRHAGIC DIATHESIS

Pathogenese und Therapie der hämorrhagischen Diathesen mit besonderer Berücksichtigung der praktisch wichtigen Fragen. Von. Dr. med. Werner Schultz. Halle a. S.: Carl Marhold Verlagsbuchhandlung, 1923.

This monograph constitutes the Band viii, Heft 6 of the series of *Verdauungs- und Stoffwechsel-Krankheiten,* edited by H. Strauss. In this study of the pathogenesis of the hemorrhagic diathesis the following features are discussed: a short review of the classification and the general pathogenesis of the hemorrhagic diatheses, the technic of the clinical examination, coagulability, hemostasis and intensity of the bleeding, the views on coagulation held by various authors, the physiology of hemostasis, the significance of the bloodvessels and the part played by such organs as the bone marrow, liver, spleen, suprarenal glands, kidneys, ovaries and the thyroid. The section on therapy includes the different factors of coagulation, such as thrombin, skeptophylactic serum and the activators of thrombin formation; also extirpation and the röntgen irradiation of the spleen. Skeptophylaxy is a term used to designate a condition of immunity to the intravenous injection of organic extracts, ascribed to an antibody directed against thrombokinase. An extensive bibliography is appended.

ELECTROTHERAPY

Lectures on Electrophysiotherapy. With Twenty Illustrations. Chicago: H. G. Fischer & Co., Inc. Pp. 350.

This book is a collection of papers by medical men, mostly in the Middle West, who are interested in physiotherapy. The discussions of these papers as well as questions asked and answered, are included. The papers were presented at a meeting held in Chicago, October 15 to 19, 1923, under the auspices of H. G. Fischer & Co., Inc., who are large manufacturers of high frequency machines. This company endeavored to bring together the men best trained in physiotherapy to interest other doctors in and around Chicago in the subject.

The papers were for the most part on the different applications of high frequency electricity but there were a few on modern x ray therapy and phototherapy, and actinotherapy. Two papers were presented by Dr. Fred H. Morse, of Boston; on the constant and electric currents. Especially worth while in this collection are the papers on physiotherapy applied to industrial work by H. I. Smith, of Chicago, and R. W. Fouts, of Omaha, Nebraska.

On the whole the book contains much on the use of medical and surgical diathermy, which would be of great value to any medical men interested to the least degree in physiotherapy, in general, and more especially in high frequency electricity. Diathermy certainly has won a place in modern therapeutics and no book so far has so completely covered this field.

PROCTOLOGY

Transactions of the American Protologic Society. Twenty-fourth Annual Session, June 22 and 23, 1923, Los Angeles, California. New York: Paul B. Hoeber, Inc., 1924. Pp. 89.

Mathews, the founder of the Proctologic Society, prefers the term "rectal specialist" to "proctologist." He says that the members of this association do important work and are benefactors to the human race. F. C. Yeomans describes a new operation, "circular amputation for marked first and second degree prolapse of the rectum." The operation itself is relatively simple, there is very little hemorrhage, and when performed under gas oxygen or preferably sacral anesthesia, there is practically no operative shock. This is a factor of prime importance when operating upon debilitated individuals. J. F. Montague publishes his important research work regarding the bacteriology of pruritus of the perineum. J. F. Saphir has an important paper on anorectal operations under local anesthesia. He concludes his paper as follows: 1. Up to date, one half of one per cent. novocaine with three minims to the ounce of adrenalin is the safest and most satisfactory solution for the production of local anesthesia in anorectal operations. 2. The circumscribed injection of the anal tissues blocks the sensation areas most satisfactorily for complete anesthesia and produces thorough relaxation of the sphincter muscles. 3. Stretching of the sphincter or dilating the anus becomes unnecessary. 4. This method of anesthesia can be successfully employed in about ninety to ninety-five per cent. of all anorectal ailments requiring operation. A few more important papers complete these interesting transactions.

COLLOIDAL CHEMISTRY

Manipulations de chimie colloïdale. Par Wo. Ostwald, professeur à l'Université de Leipzig. En collaboration avec Mm. P. Wolski et A. Kuhn. Traduit sur la quatrième édition Allemande avec l'autorisation de l'auteur. Par Edmond Vellinger. Paris: Gauthier-Villars et Cie, 1924.

The student of colloidal chemistry who finds German difficult and French easy will welcome this translation of the well known work of Ostwald on laboratory experiments in colloidal chemistry. The book contains nothing of direct interest to the practitioner of medicine.

DIABETES

A Diabetic Manual. For the Mutual Use of the Doctor and Patient. By Elliott P. Joslin, M.D., Clinical Professor of Medicine, Harvard Medical School. Illustrated. Third Edition, Thoroughly Revised. Philadelphia and New York: Lea & Febiger, 1924. Pp. vii-211.

The third edition of this little book on diabetes is intended to enlighten the patient in regard to the various phases of his disease with the idea of lengthening his life and making it more comfortable. The physician will find it of great assistance in his practice. After discussing the nature of diabetes and the recent improvement in its management, the important points in the treatment are brought out by means of a catechism. The caloric values of food and their estimation are presented in such a simple manner as to be very intelligible. Another distinctive feature is that the patient is instructed as to what information the physician desires and needs to make the patient's visits most profitable. The hygiene of the diabetic is emphasized. The chapter on the use of insulin is very instructive to both the physician and patient. The weight of the patient is given due consideration. The chapter on diabetic suggestions, recipes and menus is well worth the price of the book and more. An exhaustive table of the composition of normal foods and of the so-called diabetic foods is included. The chapter on selected laboratory tests for the examination of urine is very concise, clear and helpful. This is one of the best manuals on the subject.

MEDICAL MUSEUMS

International Association of Medical Museums, and Journal of Technical Methods. Bulletin No. 4. Managing Editors: Maude E. Abbott, M.D., and Major James F. Coupal. New York: Paul B. Hoeber, Inc., 1924.

This bulletin deals with an interesting diversity of subjects, although they all refer to some aspect of laboratory procedures. The reader turns from articles on museum technic and complicated classifications based on anatomy and pathology in use at the Army Medical Museum, Washington, to those on photography in some of its specialized phases, as the color reproduction of pathological specimens, and photographing specimens submerged in alcohol, water, or ether. There are contributions to microscopic and bacteriological technic, the purpose of the volume being to gather together those methods which are constantly appearing and which are of proved value in the laboratory, and to make the *Bulletin* a consulting reference library on laboratory technic. With this end in view abstracts of methods appearing in the current literature are included, which give in fuller detail than is usually possible in abstracts the procedures outlined.

THE BEST AND WORST OF LAWRENCE

Sons and Lovers. By D. H. Lawrence. New York: Thomas Seltzer, 1923. *Kangaroo.* By D. H. Lawrence. New York: Thomas Seltzer, 1924. *Birds, Beasts and Flowers.* By D. H. Lawrence: Thomas Seltzer, 1924.

The reprinting of *Sons and Lovers* comes opportunely as we struggle through the pages of *Kangaroo.* In the former there is much that explains him and everything he has written since, for the same peculiar pattern is there laid down for the first time. Physicians are sufficiently familiar with the disastrous effects of the mother fixation on a man's love life. Lawrence has shown in marvelous detail the web is woven more and more firmly throughout a life time of struggling, insistent mother love. Naturally Paul, his hero, cannot find a love object. Naturally, he wavers from one woman to another, with periods between when only men attract him. When his mother's death releases him, he is lost. He does not want release. He still clings to her in fantasy, a much more dangerous bond than that of reality. All his later books repeat this "lost soul" experience.

Kangaroo has little to recommend it. Lawrence apparently felt he ought to 'write up' Australia and he does so. The novel has a certain homosexual suggestiveness about it that is scarcely veiled. One always looks for the pathological in Lawrence's books now, and one finds it. Even his poetry, spontaneous and true as it is, centres relentlessly about sex, the sex act, natural functions.

It is much more diluted in *Sons and Lovers.* Perhaps we like it better in small doses. Perhaps we are not yet sufficiently free of the Victorian era to appreciate the crude ramming down our throats of "the facts of life."

AN AUTOBIOGRAPHY

Escapade. In Autobiography. By Evelyn Scott. New York: Thomas Seltzer, 1924.

There is nothing in the analysis of sensations that has escaped Mrs. Scott. She packs more sense images into the printed page than any other writer of the moment. All of which makes fascinating reading, spinning out as it does from one disaster to another, down to the lowest depths of misery. And then—salvation! $100 a month.

We believe that this book shows to a rather extraordinary degree the common tendency of bowing before circumstances, or choosing unconsciously the part that will inevitably result in disaster. The romance of suffering is an adolescent dream. Those who continue to suffer after reaching maturer years, suffer only from a prolongation of their mental adolescence. Some people find suffering very enjoyable. Such people will read this book with fervid admiration.

There is a great deal in it for the physician. It may convey to him, aside from the pathologically masochistic material, the fact that many women interpret life exclusively in terms of their own sensations. He needs some such key to understand what they are driving at in their illnesses.

Aside from the feverish atmosphere of the heroine's selfabasement (is she oldfashionedly doing penance for her breach of the public morals?), the book is vivid, beautiful, a work of art. We feel that Mrs. Scott's creative supremacy has been projected outwards in *The Narrow House* and *Narcissus.* In *Escapade* it has been turned inward with such vehemence that destruction yawns very close.

Medicoliterary Notes.

The American Medical Association has inaugurated a "package library," which means that, for a nominal charge, literature on special medical subjects, material in foreign languages, and reprints of articles by authorities on timely medical topics will be furnished from headquarters.

* * *

Because the State of North Carolina has been able to show such extraordinarily successful results from its public welfare work, the U. S. Children's Bureau has sent a special investigator there to study and appraise the system employed with a view to incorporating the results of the investigation in a pamphlet on county organization to be circularized later.

* * *

A German engineer, G. Strassburger, writing in *Die Umschau* of Frankfurt, describes a method by which it is possible to recover potential wealth from sewage, reminding us of Boffin of London, who made a huge fortune out of that city's garbage heaps. This is through the utilization of the large quantity of gases liberated from sewage including not only methane or natural gas, but heating and illuminating gases. The sewage purification plant at Erfurt has been succesfully and economically operated along these lines.

A report will soon be forthcoming on the municipal survey recently completed of Augusta, Ga. Three hundred citizens under the direction of fifty experts have been compiling inventories of every phase of community life, including child and family welfare, education, housing, recreation, industry, and agricultural conditions in the surrounding country. The results will be scientifically analyzed with a view to making use of them as a basis of future community enterprise.

* * *

One of the interesting centenary volumes of the year is Harold Nicholson's *Byron: The Last Journey, April 1823–April 1824.* (Houghton). The book is a detailed account of the poet's last journey, including a discussion of his relation to and connection with the Greek revolution.

* * *

The Connecticut State Department of Health has recently prepared and circulated a small pamphlet entitled *The Smallpox Peril: Facts and Statistics.* The primary purpose of the publication is the promotion of vaccination among the general public.

* * *

The National Amateur Athletic Association has recently announced the establishment of a Women's Division. The special purpose of this division is, not to promote unreservedly competitive athletics for women, but to prevent exploitation of young athletes, to emphasize the development of sportsmanship, and to minimize the undue emphasis at present laid upon individual accomplishment and the winning of championships. The central office of the division is at 1 East 104th Street, New York City.

Among those who made the recent attempt to reach the summit of Mt. Everest, 29,000 feet high, was Dr. T. Howard Somervell, great mountaineer, surgeon, painter, and musician. He it was who was able to record the music of the skull drums and the thigh bone trumpets played during the devil dances to which the expedition was treated at one of the Himalayan monasteries, and afterwards to transcribe and orchestrate it so that it could be reproduced in a London theatre. It is reported in England that, upon his return from Tibet, Dr. Somervell will do medical mission work in India.

* * *

At the International Congress of Refrigeration held in London last summer, forty countries were represented

Among important studies made and reported on were those on the relation of refrigeration to the dairy industry, to certain processes in rubber manufacture, and to mine ventilation. The necessity for standardization of equipment, the significance to health of cold storage requirements and standards, both stationary and in transit, the lack of standardized structural specifications, and the very slight interest and knowledge of the subject on the part of most schools and even shippers, led to the recommendation of setting up a permanent advisory committee between the refrigerating industry and university.

* * *

It is necessary for anyone who establishes a republic to presuppose that all men are bad, and that they will always apply the malignity of their mind when they have an opportunity. Men never work for good except under compulsion. *Mussolini's interpretation of the doctrine of Machievelli.*

The department of chemistry of the U. S. War Department has recently been making some interesting experiments on snake infested regions with deadly gases. In one instance chlorine and phosgene were forced into a cave known to be a den of rattlers. Although enough gas was used, in the words of one of the officers, "to kill a regiment," the snakes merely crawled about a bit uneasily, not taking the trouble even to come out of their lair. Two of the largest were caught and exposed to both gases for an hour, but were very much alive the next morning. Later they were given a heavy dose of tear gas, with no apparent effects.

"Most people who lyrically express their entire willingness to lay them down and die for Annie Laurie imagine that lady to be a mere fiction of the poet's fancy," says the *Living Age*. But this is a great mistake, we are told, for Annie Laurie is listed in a no less important work than *Burke's Peerage* as the youngest daughter of Sir Robert Laurie of Maxwelton, where there is still a portrait of her. The first version of the famous song was written by one of her suitors, William Douglas, a soldier of fortune and renowned duelist; but, true to the type of such ardent lovemaking, something happened to part the lovers, and William married another girl, while Annie Laurie herself was married two years later to another man.

* * *

A series of experiments as to the fears of children has recently been conducted at Teachers College, Columbia University, as a phase of the Institute of Educational Research. The tests were under the direction of Dr. John B. Watson.

Records of the Weather Bureau are frequently required to settle court cases. A motorcyclist collided with a work team and farm wagon in broad daylight on an unpaved roadway. He narrowly escaped death, and lingered for some months in a hospital because of an aberration resulting from the accident. But he subsequently knew enough to enter the courts armed with weather records to prove that heavy rains before the collision had muddied the road, which became deeply rutted, preventing his turning aside for the team. Because he was in the right hand path, it was decided that he had a legal right to expect the teamster to yield damages. The teamster's memory was that the road was smooth.—*New York Times.*

* * *

A French filming association has produced recently a remarkable film called *Le Miracle des Loups* in which wild wolves and human beings took part together. The leading man was badly wounded and escaped death only by killing one of the wolves with his hands.

* * *

Wealthy Hebrews in China, with influential support from his country, have inaugurated a movement to investigate and reunite with their race Jewish colonies in China that have been separated from their kind for more than a thousand years. The revival of interest is due chiefly to Adolph S. Oko, librarian of the Hebrew Union College of Cincinnati, who recently brought from Europe a collection of manuscripts that show conclusively the relation of the Chinese Hebrews to those of the western world.

The Harleian Miscellany, edited by Henry Savage and published in London by Cecil Palmer, is an interesting selection from the tracts and pamphlets in the library of Edward Harley, second Earl of Oxford, and was first published in 1744. It is a collection of curious lore, scandals, history and gossip of the times, and a commentary on the rather sadistic tastes and pursuits of many of our forebears.

* * *

One of Putnam's recent publications is *Psychographology,* by Eugene S. Bagger, a study of Raphael Scherman, the man who professes to read "visions" in handwriting.

* * *

The Department of Commerce has recently received from the Consul General at Copenhagen a report on the new law passed by the Parliament of Iceland. This law is to be effective for two years, and prohibits from import ready-made clothes, shoes, all kinds of bread, butter, cheese, salt pork, sausages, eggs, fruits, leather goods, oils, soap, furniture, pictures, films, watches and clocks, motorcycles and automobiles, and all jewelry and novelties. The law was passed in an effort to raise the value of the Icelandic crown. It will mean among other things that, when the present stock of shoes is exhausted, the people will have to resort to the native sealskin shoes, and that the homespun industry will be revived.

* * *

Commenting on the recent plague of caterpillars in England, the *Manchester Guardian* says: "No one nowadays seems to think of fighting the caterpillars which are ravaging Kent and Surrey orchards by means of the law, secular or ecclesiastical, as was the recognized procedure centuries ago. In 1120 the Bishop of Laon pronounced a solemn sentence of excommunication against caterpillars and grasshoppers in his diocese; and as late as 1516 an admonition was issued by another bishop declaring: 'We grant the request of the inhabitants of Villenoce, and warn the caterpillars to retire within six days, in default of which we declare them accursed and excommunicated.' With a commendable sense of justice, an advocate was sometimes appointed to plead the cause of the insects against that of the farmers before judgment was delivered."

Abstracts from Current Literature

NEUROPSYCHIATRY

Significance of the Rapidity of Sedimentation of Erythrocytes in Psychiatry.—A Glaus (*Schweizerische medizinische Wochenschrift,* March 13, 1924) arrives at the following conclusions regarding the sedimentation reaction in the most important groups of psychoses: Senile dementia shows acceleration, especially so in Alzheimer's disease. Syphilis of the brain and general paresis show acceleration, being especially marked in advanced cases with marasmus. Manic depressive insanity shows little or no marked acceleration (the cases examined were mostly melancholias). Psychopathy, neurasthenia and hysteria show little or no acceleration. In schizophrenia the reports are contradictory—slight or no acceleration. In the consideration of the subgroups, catatonia, especially in the acute stages, could be differentiated fairly sharply from the other groups by a relatively marked acceleration. There is a more or less characteristic "formula of rapidity" in the mixing test for catatonia. To what extent hebephrenia, etc., can be differentiated from the other subgroups by the mixing test is still a moot question. As a rule an accelerated sedimentation is not observed in paranoia. In epilepsy there is no or only a moderate acceleration and perhaps immediately after an attack there is more marked acceleration. This test requires further study and the subject is by no means as yet exhausted.

Malaria Therapy in General Paralysis of the Insane.—In a series of forty cases of general paralysis treated by inoculation with malaria, sixteen of which received in addition a course of salvarsan, A. R. Grant and J. D. Silverston (*Lancet,* March 15, 1924) made observations and comparisons on the findings in the cerebrospinal fluid and blood. In every case there was some alteration either in the fluid or serum or in both following treatment. The earliest signs of improvement were manifested by a diminished lymphocytosis and lowered globulin content of the cerebrospinal fluid and by a reduction in the intensity of the blood Wassermann reaction. A combination of all three changes occurred in forty per cent. of the series. The Wassermann reaction of the colloidal gamboge reaction and the colloidal gold test were favorably influenced at a somewhat later period. Combined improvement in the cell count, protein content, and Wassermann reaction of the cerebrospinal fluid took place in 18.7 per cent., and with the gold-sol test in 6.2 per cent. of the whole series. The Wassermann reactions of the cerebrospinal fluid and the blood serum were negative in twenty-five and 18.7 per cent. respectively—concurrently in both in five per cent.

The Question of Individual Psychology in Relation to Psychiatry.—Henrik Sjöbring (*Inaugural thesis for promotion to the degree of Med. Dr.,* Upsala, May 26, 1913) states that the general principles of psychiatry in analyzing mental processes fail to take cognizance of individual psychology. An abstract consideration of the group of symptoms presented by the subject rather than the subject *in concreto* places it in this or that category and defines the psychosis. Thus hallucinations and delusions point to a definite genesis and from the varied stigmata one arrives at the type.

When the aggregate of components, normal and abnormal, that constitute the psychic entity, fail in their harmonious functioning and the disorder is made manifest by purposeless activity, by failure to react to its varied contacts, by insufficiency in relation to its requirements, by lack of adaptation to its environment, by inability to fit into its *milieu,* the quest becomes a farreaching one to ascertain and determine teleologically the origin of the morbid phenomena. Whether it be the elements of inherency and predisposition and the complex thereby constituted, or whether extraneous influences contribute to the unbalancing of the mental mechanism.

The grouping of mental abnormalities under two heads, the *degenerative* or functional and the *organic,* defines these according to their salient or causal factors, the former where primal inherency plays the chief rôle and the latter in which external agencies, such as physical trauma, nutritional faults of toxic irritants causing somatic changes, are the contributing etiological factors in the development of mental unbalance, whether it remain a latent tendency or takes shape as a psychosis, varying in degree from a slight loss of correlation to a complete disintegration of the component elements that make up the psychic unity.

The author's plea is for the recognition of individual psychology as a special domain of psychiatry, for a careful tracing of this and that syndrome to its origin, for a closer determination of the particular inherency that constitutes the personality as abnormal, for on this and on the expression of its psychic activities we base our knowledge and determine the concrete personality, which is the object of individual psychology.

Treatment of General Paralysis.—James Purves-Stewart (*British Medical Journal,* March 22, 1924) speaks in favor of an improved plan of supplementing malarial inoculation in the treatment of general paralysis by introducing salvarsanized serum directly into the cisterna magna and roof of the fourth ventricle by means of a suboccipital or cistern puncture, according to the technic of Wegeforth, Ayer, and Essick. Serum introduced into this situation flows forward with the current of the cerebrospinal fluid to the basal cistern and thence upward to the cortical subarachnoid space, directly reaching the diseased cortical areas. Weekly intravenous injections of salvarsan, with fortnightly intracisternal injections of salvarsanized serum, are carried out systematically. Daily mercurial treatment by mouth is also given throughout. The cerebrospinal fluid and blood are examined at every injection, and the treatment is continued not only until the clinical symptoms, physical and mental, have cleared up, but until the cerebrospinal fluid becomes normal, as evidenced by the disappearance of the pleocytosis and by a negative Wassermann reaction.

Lumbago.—F. Zollinger (*Schweizerische medizinische Wochenschrift,* April 10, 1924), studied about five hundred cases of lumbago from the viewpoint of accident insurance. In private practice among noninsured patients this condition is so diagnosed and correctly treated with salicylates. In accident insurance practice it is usually considered as a sprain of the muscles or spinal joints and also treated with salicylates. In the former group a feeling of stiffness often precedes the acute pain. Affections of the nose, throat, or teeth are usually present. The pains are often associated with alcoholism. The dorsal muscles and tendons are not easily torn and the pain does not usually last long. Contracture of the muscle, functional scoliosis and Lasègue's sign of sciatica are commonly present in lumbago. The author considers this condition as an infectious neuritis, which may be aggravated by an accident. Only patients who can prove some sudden incoordinated muscular action at the moment of the onset of pain should be considered as fit subjects for accident indemnity.

The Blood Sugar and Sugar in the Cerebrospinal Fluid in the Insane.—M. Dide, G. Fages and A. Bauduin (*Presse médicale,* May 14, 1924), present the results of a research on this question in fifty-six cases. They find a striking contrast between the diseases of the brain (congenital or acquired brain lesions, senile dementia, presenile delusions) and the constitutional affections (cyclic insanity, progressive delusional insanity and systematized delusional insanity). In the case of acquired cortical lesions, the blood and spinal sugar are normal or depart but slightly from it. Sometimes there is even an increase of blood sugar in the presenile cases. In cyclic insanity, the blood and spinal sugar are normal in the quiet periods; in the course of recovery there appears to be a parallel rise in the blood and spinal sugar, whereas in the premonitory period preceding the attack there had been a reduction of the blood sugar with a marked rise of the spinal sugar. During the attack, the spinal sugar seems slightly increased. Dementia precox is rather frequently characterized by a reduction of the blood sugar, although at times the same patients may show hyperglycemia, without any apparent cause other than a modification in the mental state. The spinal sugar is seldom normal, never lowered, and generally increased, without any obvious relationship to the variations in the blood sugar. In spite of the great muscular activity attending

the epileptic seizures the blood sugar is never increased, but frequently lowered, whereas the spinal sugar is always increased, sometimes to an enormous extent. These findings appear to support the sympathetic pathogenesis of the constitutional psychoses. One of the authors (Dide) has described dementia precox elsewhere as a complete sympathetic syndrome and the other psychoses as partial sympathetic syndromes. Only a disturbance of vegetative innervation could give rise to marked, cyclic variations in a fundamental metabolic process such as that appertaining to glucose, which Derrien and Piéron have shown to occur in emotional seizures. Epilepsy seems like the constitutional psychoses in being dependent on a sympathetic disturbance, especially appreciable in the endocrine glands, but is more especially related to vasomotor conditions in the nerve centres. Apart from these hypothetical considerations, it seems undeniable that the constitutional psychoses are attended with changes in the spinal sugar—usually a nincrease; that the critical periods are marked by an accentuation of this rise in spinal sugar; that the blood sugar is often low in dementia precox, and that epilepsy is attended with a persistent increase of spinal sugar together with a tendency to hypoglycemia.

A Contraindication to the Use of the Derivatives of Malonylurea.—A. Tardieu and A. Médioni (*Journal de médecine de Paris,* April 26, 1924), note that the clinical manifestations of poisoning are the same with all the derivatives of barbituric acid, including barbital (veronal), phenobarbital (luminal), and somnifen (combination of the diethylbarbiturate and diallylbarbiturate of diethylamine). These manifestations include coma and a rather characteristic dysarthria, with a special puckering of the labial commissures and a paretospastic difficulty in articulation suggesting rather closely that of general paralysis. There have also been repeatedly reported a central external ophthalmoplegia with diplopia and morbilliform or urticarial eruptions. The authors' case was that of a woman with extensive ascites and severe pains in the right hypochondrium, resulting in insomnia. Somnifen was given for six days in doses of thirty drops, but this was followed by delirium with restlessness, visual hallucinations, and incoherent logorrhea. After an interval of two days, the drug was renewed in the same dose for ten days. Unable to sleep, the patient then swallowed all that remained in the bottle, viz., six mils, corresponding to 0.6 gram each of diallylbarbituric acid and diethylbarbituric acid (veronal) and 0.3 gram of diethylamine. A few minutes later, she passed into a state of deep sopor, from which even the strongest stimulants failed to rouse her. Her limbs were completely inanimate, all reflexes abolished, and respiration quiet but shallow and accelerated (26 a minute). The pulse was thready and almost imperceptible, at a rate of 140 a minute. The extremities were cold and cyanotic and the temperature rose to 39° C. Death took place from heart failure twenty-four hours later. The conclusion reached from this case is that the drugs of the malonylurea series should not be prescribed in cases with organic or functional disease of the liver, including tuberculous, syphilitic, alcoholic or malarial cirrhosis. If delirium of the confusional type develops during their use, it will be well to discontinue their administration.

Quinine Urea Injection for Sciatica.—A. E. Hertzler (*American Journal of Surgery,* April, 1924), finds an injection of quinine and urea hydrochloride vastly more effective than tropacocaine, stovaine, etc. A solution of one per cent. quinine and urea hydrochloride is used. From fifteen to thirty c.c. are injected into and about the nerve at the point where it lies over the neck of the femur. This point is selected because when the neck of the femur is reached by the point of the needle the operator knows the needle has been passed deeply enough and that if the nerve has not been located the direction of the needle must be changed.

The technic is as follows: The patient is placed on the unaffected side with the affected thigh half flexed. A point is selected on the line between the tuberosity of the ischium and the great trochanter, somewhat lateral from the midpoint, the exact distance depending on the size of the patient. When the patient stands erect the nerve passes over the edge of the acetabulum, which is a point midway between the bony landmarks just mentioned, but when the leg is semiflexed, the nerve glides to the side along the neck of the femur. It is at this point that the needle must strike it.

A wheal is first made in the skin with a fine needle. A larger needle, long enough to reach the depth required (preferably one of eighteen gauge, and four or five inches long) is passed slightly upward as it goes into the depth. If it strikes the nerve the patient will feel a pain shooting down the leg along the line of his former pains. The operator will perceive a sensation as if the needle had passed from muscle into rubber tubing—a peculiar elastic resistance. If the nerve is not struck the needle will strike the neck of the femur. The operator must then partly withdraw the needle and start in a new direction. Usually he will find that his needle has been passed too far medially. Patient search must be made until the nerve is located—by no means always a simple matter particularly in stout patients. The solution to the amount indicated is deposited in this region. In thin subjects I use the lesser amount and in stout patients and for repeated injections the larger amount is used. I usually try to inject five cc. of the solution directly into the substance of the nerve and the remainder in its immediate vicinity. Recent or mild cases are usually cured by one injection. Severer cases should be reinjected after a week. Severe, longstanding cases, particularly those complicated by scoliosis, may require as many as four or five injections. The intervals between the treatments should be a week or two.

If the injection is made into the nerve a cure is certain. Usually the first injection produces a marked improvement. In rare instances the condition seems to be aggravated but this passes off within a few days. There have been no complications or unpleasant sequelæ, and so far as I know there have been no recurrences.

Encephalitis Lethargica.—H. E. Foster and J. R. Cockrell (*American Journal of the Medical Sciences,* May, 1924) assert that the main points to be considered from a study of the quantitative sugar determinations made on the fluids from thirty-five cases of encephalitis lethargica are:

The determination of the sugar content of the cerebrospinal fluid should be made by a reliable quantitative method; an amount of sugar above 0.0600 per cent. was obtained in ninety-one per cent. of the fluids studied, using the Folin-Wu method; quantitative sugar estimations are valuable in differentiating encephalitis lethargica from tuberculous meningitis and as an aid in other conditions presenting similar symptoms; the amount of sugar present in the cerebrospinal fluid is not pathognomonic of encephalitis lethargica but is of recognized utility in making the diagnosis.

Masked Malaria Following Malaria Treatment in General Paralysis and the Possible Relationship Between Epilepsy and Malaria.—Emil Redlich (*Wiener klinische Wochenschrift,* February 7, 1924) has observed that during the febrile attacks of malaria, especially in predisposed individuals, as children, epileptic and epileptiform attacks may appear. This is a usual occurrence in all febrile infectious diseases, which may be explained by toxic, possibly vasomotor, or other factors resulting from infection. The author has also observed epileptic attacks as a substitute for masked malaria, occurring independently in isolated cases. In this respect these resemble other nervous and psychic phenomena of masked intermittent fever, as mentioned above. Their explanation is not easy and the factors of infection must be drawn upon in explanation. A predisposition of a general or special nature, cannot be assumed to exist, at least not in the majority of cases. In isolated cases the epileptic attacks have been observed to occur subsequently, constituting chronic epilepsy. These cases lead to the question whether a previous malaria has existed even without a masked intermittent fever giving rise to chronic epilepsy. The pathogenetic significance of these cases must be sought in the cerebral changes induced by the malaria, and consequently cerebral hemiplegia and pigmentary emboli and also clogging of the capillaries by parasites and capillary and precapillary hemorrhages must be thought of. In addition, more recent investigations, especially in tropical malaria and pernicious anemia, have revealed a series of other microscopical changes, such as infiltrations of the meninges and vascular sheaths with hematogenic cells, proliferation of the vascular endothelium proliferation of the glia with neuronophagia, and peculiar proliferations of the glia cells, which have been designated as malarial granulomas. It is evident that such cerebral changes, just as well

as other lesions, may produce a predisposition for the occurrence of epileptic attacks, whereupon other injuries, such as great heat, may produce the attacks, resulting finally in chronic epilepsy. In these cases antimalarial therapy has little effect as regards the epilepsy.

Mental States in Alcoholism.—Bedford Pierce (*Lancet*, April 26, 1924), states that the alcoholic psychoses present few specific features. The author studied the effect of a single dose of alcohol on inhibition and on instinct and he found that the primary influence of alcohol is on the vegetative nervous system. It produces a dilatation of the peripheral vessels and it also acts, possibly, on the nervous mechanisms involved in the expression of the emotions, including the endocrine organs. However, it is difficult to draw definite conclusions. Alcohol affects markedly the three primitive instincts—the herd, the sexual and the ego.

MALIGNANT GROWTHS

Cancer and Pregnancy with Special Reference to Cancer of the Breast.—W. Odermatt (*Schweizerische medizinische Wochenschrift*, April 24, 1924) found that transfusion with the blood of young persons inhibited the development of cancer of the stomach in two out of sixteen cases. The precancerous stage of carcinoma of the breast (glandular infiltration, retraction of the nipple) shows a tendency toward a more rapid malignant growth during pregnancy and lactation and clinically definite carcinomas grow more rapidly and metastasize on the advent of pregnancy. Pregnancy also usually favors the development of recurrences and metastases after the tumors have been subjected to radical operation postoperative irradiation. Except in inoperable cases, it is therefore proper to advise interruption of the pregnancy and avoidance of subsequent pregnancy.

Primary Sarcoma of Mediastinum and Lungs.—C. A. Peters (*Medical Clinics of North America*, May, 1924) draws the following conclusions: 1. Sarcoma of the mediastinum and lungs is a relatively common disease. 2. It is often difficult to say which is involved first unless the case is seen early. 3. The mediastinum is more often the original seat of the growth. 4. Sarcomas grow slowly but extensively, and select the line of least resistance, but some definitely invade such structures as the pericardium and heart. 5. They may metastasize in the lung, and if a vein is ruptured metastases may be found in any organ. 6. There may be extensive involvement for a long time with only a moderate loss of weight, and the other signs which one usually associates with malignant disease.

Carcinoma of Gallbladder.—J. B. Deaver (*American Journal of Surgery*, May, 1924) says that, if, as most authorities believe, gallstones are exciting factors in the development of cancer, it would seem that here one is fortunately dealing with a demonstrable precancerous disease which can be effectively eradicated by the removal of the benign disorder known as cholelithiasis. Cancerous transformation of a gastric ulcer is no longer doubted in many quarters. The evolutionary process of gallstones is an analagous one, since it is the presence of the stones that leads to possible necrosis and prolonged ulceration, with consequent epithelial proliferation and cancerous changes. Therefore, the possibility of cancer as a sequel of gallstones must form a part of the prognosis of calculous cholecystitis and must enter into consideration in deciding for or against operation.

Carcinoma of the Antrum.—F. M. Johnson (*Surgery, Gynecology, and Obstetrics*, June, 1924), presents the following conclusions:

1. Cancer of the antrum must be recognized in the early stage before any method of treatment will produce uniform and favorable results. The opportunity is given to rhinologists and dentists, but facts indicate the tardiness with which they make an accurate diagnosis.

2. Conservative surgery combined with radium promises to give better results than does the radical operation.

3. Palliation for a large number of hopelessly advanced cases is possible through the conservative use of radium.

4. The successful application of radium depends on an adequate exposure of the area. As a rule an oral approach is best, but if conditions demand it the eye should be removed and the floor of the orbit opened.

Carcinoma of the Rectum.—R. C. Coffey (*Surgery, Gynecology, and Obstetrics*, June, 1924), holds that the two stage operation obtains the best results. The principles to be adopted for the first stage are: 1. A completed physiological abdominal mechanism must be provided which is not to be disturbed afterward. 2. Complete devascularization of the involved and adjacent tissues from above. At the same time the devitalized structures must be mobilized and pushed down within easy reach of a sacral or perineal incision. 3. Separation of the retained physiological area from the discarded area by a quarantine pack which also serves the purpose of draining away the débris of any sloughing tissue resulting from devascularization.

He describes this first stage operation in detail for three different types of cancer. When the operation is completed it is halted until a complete anatomical and physiological abdominal mechanism has been reestablished. By this he means that the sutured peritoneum above the quarantine has firmly healed, the abdominal wound has healed, the artificial anus is firmly established and acting well, the patient's pulse and temperature are practically normal and the patient's digestive apparatus is functioning normally. This is usually completed about the tenth day after the operation. Occasionally, we do the operation a little earlier but sometimes the second operation is delayed several days longer until the patient is in a good healthy condition. In the meantime the enemy, the cancer, has been largely cut off from its support, is quarantined from the rest of the body to a large extent, and is almost harmless for the time being. The most startling and spectacular thing that takes place during this interval between operations, is the line of cleavage between the tissues which have been devitalized and are to be removed and the normal structures which are to remain. This change makes the second operation a minor affair.

The second stage operation is also described in detail, for both men and women. It consists mainly in cutting away the growth within the lines of cleavage, which, owing to the interval between operations have become definitely formed. This is the main argument in favor of the two stage operation, and concerning it the author says: The definiteness of the line of cleavage around the fascia propria of the rectum and the ease with which the second operation is performed is amazing to anyone doing the operation for the first time or even observing its performance. The causes of this line of cleavage or edematous area is probably due to the complete shutting off of the circulation from above which largely devascularizes the perirectal tissues inside the fascia propria at the first operation. This line of cleavage seems to be comparable to the line of demarcation in gangrene and occurs at the point at which the normal circulation outside the fascia propria encounters the devascularized area at the fascia propria. It does not occur in the absence of devascularization and as far as I know it does not occur in the absence of drainage or the quarantine which of necessity follows devascularization.

Primary Sarcoma of the Esophagus.—C. E. Smith and G. Y. Rusk (*Annals of Surgery*, November, 1923) report upon recorded cases and one of their own as follows:

Including our case, thirty-five cases of primary sarcoma of the esophagus have been reported. The average age of these patients is 53.6 years. The condition is much more common in men. Where sex is given there are twenty-six men and seven women.

Practically every patient showed dysphagia due to stenosis or obstruction by the tumor. Pain was present in many cases, its location varying according to the site of the tumor.

It seems probable that in all cases, except those of myosarcomata, the growth originated in the submucosa.

Sarcoma of the esophagus apparently grows more rapidly than carcinoma, but metastases do not seem to occur as frequently as one usually finds in sarcoma elsewhere in the body.

In many cases gastrostomy was necessary, due to stenosis or obstruction in the esophagus caused by the new growth. In only one instance, the second case of von Hacker, was resection of the esophagus performed. The growth recurred in adjacent tissue in the cervical region and the patient died three months later of bronchopneumonia.

It seems possible that operation might affect a cure if the patient is seen early, especially in a case of the more slowly growing, polypoid fibrosarcomata such as our own.

OBSTETRICS

Kielland Forceps.—Among his cases, Günther Conrad (*Zentralblatt für Gynäkologie,* March 22, 1924) never met with any unfortunate results and he believes that the Kielland forceps is a universal instrument applicable for every type of presentation of the head and at every level of the pelvic plane provided the proper indications are present, because this forceps grasps the head in every position in the most ideal way biparietally. It was applied with good results even in generally contracted pelves. The technic of application is easily acquired. The reduction in the danger to the mother and child is so striking that it cannot be denied and therefore the Kielland forceps may be entrusted to the general practitioner.

Value of the Kielland Forceps.—Theodor Wyder (*Zentralblatt für Gynäkologie,* March 22, 1924) asserts that the only forceps that can be entrusted to the hands of the general practitioner is one which does not make any great technical demands and does not lead him to difficult and dangerous applications of the same. The best forceps for that purpose are those with moderate pelvic curves, such as the model of Naegele and others. There is, therefore, no good reason why the Kielland forceps should replace the other types. In the vast majority of cases demanding the application of forceps the Kielland forceps does not have the slightest advantage over its predecessors.

The Place of the Kielland Forceps in Obstetrics.—Th. Wyder (*Schweizerische medizinische Wochenschrift,* March 13, 1924) believes that the use of the Kielland forceps should not be abandoned. It denotes progress insofar as it facilitates the rotation of the head, but it does not advance the indication for forceps. It should be used only by experienced obstetricians and should not therefore be entrusted as yet into the hands of the general practitioner.

Injuries to the Skull from Kielland Forceps.—Karl Fink (*Zentrablatt für Gynäkologie,* February 23, 1924) reports five cases in which the skull was injured by the Kielland forceps in spite of the presence of a normal pelvis, a normal size of the head and the most careful diagnosis and indications. These experiences show that too great a traction and powerful rotation with the Kielland forceps should be avoided if unforeseen conditions arise. Otherwise too great a pressure is exerted on the temporal bones and the skull bursts.

Hydrostatic Bag for the Induction of Labor.—George H. Lee (*American Journal of Obstetrics and Gynecology,* March, 1924) describes a bag which combines the good features of the Barnes fiddle bag and of the Champetier de Ribes and Voorhees bags. It has a constricted portion which rests in the cervical canal so that, when in place, it will distend the cervical canal and also a large portion that will rest in the lower uterine zone and act as an irritant to excite uterine contraction. The distal dilatation is globular in shape and so fashioned that it will rest in the vagina. A small tube of only one cm. in diameter communicates with the exterior, which tube is not sufficiently large to distend the vulva and keep it open. This bag is constructed of rubber fairly heavy, sufficiently so to permit a weight to be fastened to the tube that protrudes from the vulva, when necessary.

Pressure Changes in Craniovertebral Canal of Fetus.—B. Crothers (*Surgery, Gynecology, and Obstetrics,* December, 1923) presents the results of the imposition of force upon the fetus during delivery considered from a neurological and physiological point of view.

The most important lesions, directly referable to force, are: 1, rupture of the falx or the tentorium, and 2, rupture of the cervical spinal column. These lesions are not in themselves fatal, but they expose the medulla and the upper cord to injury.

Under ordinary conditions the medulla is guarded from harmful pressure by the tentorium, which modifies and controls force imposed upon the vertex, and by equilibrium of fluid pressure at the foramen magnum, which prevents downward dislocation of the contents of the posterior fossa. This balance of pressure can be upset and herniation of the cerebellum and medulla produced by rupture of the dural septa or by combinations of forces which maintain or increase intracranial pressure while diminishing spinal pressure.

Breech extraction, as usually performed, brings dangerous and unphysiological forces into play. Pathological evidence shows that rupture of the tentorium occurs in eighty-eight per cent. of the still births following socalled normal breech labors. In addition a considerable number of injuries of the vertebral column or of the spinal cord can be logically attributed to traction during breech deliveries.

Aside from the gross injuries, which account for about half of the death rate in viable newborn babies, various alterations in pressure during delivery and certain manouvres during resuscitation may produce fatal or disabling lesions within the central nervous system.

Asphyxia, as commonly described in obstetrical literature, is vaguely defined. Pathological and experimental evidence of its existence is not available. While the absence of proof is not in itself evidence against the obstetrical conception, it invites challenge. The pathological findings, particularly those in babies dying after breech delivery, raise the question whether efforts to avoid fetal asphyxia may not add to the already great risk of injury to the contents of the craniovertebral cavity.

Breech Presentations; Prophylactic External Version. G. H. Ryder (*Surgery Gynecology, and Obstetrics,* November, 1923) says that the safest method of treating breech presentations is by prophylactic external version.

External version not only reduces the fetal mortality, but renders labor shorter and more natural for the mother.

The operation is safe, if done without force.

The best time for performing external version is usually the seventh and eighth calendar months.

The operation is generally quite easy and may usually be performed without ether.

When at all difficult, a general anesthetic should be used. Under this, in most cases, except late in labor, external version is easily performed.

Force should never be used. If version can not be accomplished without force, the operation should be given up.

When external version is once performed, the fetus occasionally resumes its original presentation, but usually does not. This is more likely to occur when the version is very easy. Consequently, the fetus may be re-turned as frequently as necessary, even early in labor. When external version is difficult, spontaneous reversion is not apt to occur.

External version performed early gives warning of disproportion between the head and the pelvis, by observation of the way in which the head settles into the pelvis or may be crowded in by the obstetrician.

Finally with careful observation in the latter months of pregnancy, external version should reduce the fetal mortality of breech presentations approximately to that of cephalic presentations; and furnishes one more argument for careful antepartum examinations.

Transperitoneal Cervical Cæsarean Section.—L. E. Phaneuf (*Surgery, Gynecology, and Obstetrics,* December, 1923) discusses the Beck, Kroenig, and Hirst operations with tabulated results of each, and concludes as follows:

1. The transperitoneal Cesarean section offers protection against septic peritonitis.
2. There is practically no shock as the intestines are not handled.
3. There is less bleeding.
4. The mother has a much easier puerperium.
5. There is better healing since the incision is in the cervix, the noncontractile part of the uterus.
7. There is less danger of rupture in subsequent pregnancies and labor.
7. An efficient test of labor may be given with safety.
8. The Hirst operation is best in doubtful cases, and the Kroenig or Beck operations in clean cases.

Eclampsia and the Weather.—As a result of his studies, A. Hoënhorst (*Zentralblatt für Gynäkologie,* January 26, 1924) comes to the conclusion that there probably exists some relationship between climatic conditions and variations, on the one hand, and the frequency of eclampsia, on the other. Etiologically, the factor of weather (dampness) comes up for consideration only as an excitant, as it probably affects injuriously upon the detoxicating and excretory organs of the body and consequently results in a stasis of the toxins which produce the disease picture of the eclampsia.

NEW YORK, WEDNESDAY, OCTOBER 15, 1924

Medicolegal Notes.

NEGLIGENCE IN TREATING FRACTURED FEMUR HELD FOR JURY

In an action for negligence in the treatment of a fracture of the femur of plaintiff's leg the Minnesota Supreme Court held, Anderson v. Satterlund, 197 N. W. 102, that it was for the jury to determine whether the overriding of the broken ends of the bone resulted from the defendant's failure to exercise proper care and skill. The evidence showed that in applying the cast the full length of the leg he was following an approved method of treating a fractured femur, that it was not bad practice to use the cast without attaching a weight to the leg, and that the ends of a broken femur cannot always be kept from overriding, no matter what method is employed to reduce the fracture. It was held that the proper treatment of the leg after the bone was set was also for the jury. There was an interval of four weeks between the date when the cast was applied and the date when defendant discovered the broken ends of the bone were no longer in position. When the ends slipped was left in doubt. It might have been a gradual process or it might have occurred suddenly. The medical witnesses agreed that a fracture should be watched closely. The event which happened was not so unusual that it could not have been anticipated. It was held that the jury might find that in the exercise of reasonable care the defendant should have done more than he did to ascertain from time to time whether the bone was uniting properly, and that, while the showing of a failure to exercise reasonable care and skill was not clear or convincing, the evidence furnished a basis for a rational inference that there was negligence in that respect. Judgment for plaintiff was affirmed.

PERSONS ELIGIBLE AS CHIROPRACTIC EXAMINER IN CALIFORNIA

The California Supreme Court holds, People v. La Barre, 224 Pac. 750, that the language of the State Initiative Act, giving the Governor power to appoint a board of chiropractic examiners, furnishes convincing proof that it and the Medical Practice Act are to be construed, in so far as consistent, in pari materia, section 18 providing that it shall not be considered as repealing the Medical Practice Act, except as that act may be in conflict with the Initiative Act as applied to persons licensed under the latter act, and section 13, providing that "chiropractic licentiates shall observe and be subject to all state and municipal regulations relating to all matters pertaining to the public health."

The Initiative Act provides that: "Each member of the board first appointed hereunder shall have practiced chiropractic in the State of California for a period of three years next preceding the date upon which this act takes effect, thereafter appointees shall be licentiates hereunder." This provision, it is held, contemplates the appointment of persons lawfully practicing under licenses issued under the Medical Practice Act, the word practice meaning engagement in the treatment or healing of the sick in accordance with the rules which the state in the exercise of the police power has prescribed.

NEGLIGENCE NOT SHOWN IN USE OF RADIUM FOR CANCER

In an action for damages alleging negligence in burning plaintiff with radium while treating her for cancer, the Iowa Supreme Court holds, Furgason v. Bellaire, 197 N. W. 13, that it is necessary in cases of this character to show that defendant failed to exercise the knowledge and care usually and ordinarily exercised by practitioners in the same or similar localities, and that the evidence, which was very meagre on the point, did not indicate that the defendant failed to observe the usual and ordinary practice of his profession in applying the radium or in the treatment of the plaintiff after such application. Judgment for the defendant was therefore affirmed.

LOSS OF EYE HELD NOT DUE TO PRIOR OPERATION

In a proceeding under the Washington Workmen's Compensation Act, the question was whether ulcers causing the loss of the claimant's eye were the result of an operation for neuralgia, evulsion of the root of the fifth nerve on the right side of the face, or of sawdust being blown into the eye while the claimant was at work. The testimony of experts showed that the operation would have the effect of interfering with the winking of the right eye and the natural bathing of the eyeball, which would become dry, in which case ulcers would form on it. Two of the four experts testified that the operation probably would cause such ulcers, necessitating removal of the eye. The other two testified that such an operation would seldom cause a loss of the eye. As there was positive testimony of sawdust being blown into the eye, followed by inflammation and an increasing dimness of the eye, and all the experts testified that foreign matter coming into the eye may cause ulcers thereon and necessitate its removal, the Washington Supreme Court held, Hamilton v. Department of Labor, 224 Pac. 387, that the claimant had proved his case.

CONSULTATION OF OR ATTENDANCE BY PHYSICIAN WITHIN MEANING OF INSURANCE APPLICATION

The Oklahoma Supreme Court holds, Sovereign Camp W. O. W., v. Brown, 221 Pac. 1017, that the mere calling into a doctor's office for some medicine to relieve a temporary indisposition cannot be considered an "attendance by a physician," nor a "consultation of a physician," within the meaning of an application for insurance stating that insured had not consulted nor been attended by a physician within five years of the date of application.

DEATH BY EFFERVESCENT MEDICINE HELD ACCIDENTAL

The Iowa Supreme Court holds, Gohlke v. Hawkeye Commercial Men's Association, 197 N. W. 1004, that death resulting from the closing of the glottis after taking a dose of sal hepatica may be said to be the result of external and accidental means entitling a beneficiary to recover under an accident policy. The court holds that the voluntary taking of a nonpoisonous, harmless remedy, even though taken in a manner to produce, by effervescence, a gas that would be irritating, but which was not expected or intended to produce injurious results, would, where such a result unexpectedly follows, be a violent external and accidental means.

COMPENSATION FOR RECURRENCE OF INJURY

A miner received a severe contusion of the right shoulder, evidenced mostly by lack of function of the right arm. was pronounced "surgically healed" and resumed work for two months, when he was again injured, when throwing a lever forward paralyzed the arm for the time. The only medical witnesses testified that this was a recurrence of the first injury, which might come from any movement of the arm. The Utah Supreme Court therefore holds, Continental Casualty Co. v. Industrial Commission, 221 Pac. 852, that payment of compensation could not be awarded against an insurance company not insuring at the time of the original injury. An accident by which a diseased condition of the body is accelerated is different from a recurrence of an injury, and where there are two accidents the question whether the disability is attributable to the first or second depends on the circumstances of each case.

Trustworthy!

The extent to which innumerable practitioners of medicine are today employing

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

whenever a dependable reconstructive tonic is called for, tells in no uncertain way of its therapeutic utility and gratifying efficiency.

During the thirty-five years this reliable tonic has been at the service of the profession, the quality of its ingredients and the unvarying character of the composite product have been consistently and faithfully maintained.

Thus it is easy to understand why the host of medical men who have learned how reliable it is in its character and results, not only take pains to order the original Gray's Glycerine Tonic Comp. (P. F. Co.), but also to see that their patients get no other!

Such care is well worth while, for it often measures the difference between success and failure.

The Purdue Frederick Co., 135 Christopher St., New York

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach** in **Pregnancy**, for **Rapidly Restoring** the **Vital Forces** in **Hemorrhage**, for **Sustaining** and **Strengthening** in **Long** and **Exhausting Labor**, **Valentine's Meat-Juice** is extensively employed in

Obstetrical Practice.

VALENTINE'S PREPARATION
NUTERO PERFECTA
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS—Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Dr. E. Duloroy, *Physician Accoucher to the International Hospital, Paris, France:* "A young accouchée, in a very weak condition and suffering from stomach trouble, could retain no food, but was able to assimilate VALENTINE'S MEAT-JUICE given at first in small doses. An improvement was quickly visible, the patient recovered her strength and is today in good health."

Dr. Javier Ortis y Ferrer, *Physician to the Municipal Charity of Madrid, Spain:* "VALENTINE'S MEAT-JUICE has given the happiest results in cases of debility and in the asthenia produced by operations of confinements. In some cases of Tuberculosis it restored exhausted strength, and in every case where organic exhaustion manifested itself as an effect of disease."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY,

Richmond, Virginia, U. S. A.

S 130

Miscellany.

Psychological Research Planned at Yale University.—Announcement has been made by the authorities of Yale University of the establishment of a new institute for research in fundamental problems of psychology. This movement has come as a response to demands for basic data in psychology for use in industry, in medicine, in education, in social work, in child welfare, and in various public problems. The institute is to be an integral part of the university, and will be open to graduate students from all parts of the United States and from foreign countries. In addition to purely human psychology, the reactions of animals will be studied, for the light they can throw on certain phases of human behavior.

Three new members, all men of national reputation, have been added to the Yale faculty, to comprise the staff of the institute. Dr. Robert M. Yerkes has been called from the National Research Council at Washington, Dr. Raymond Dodge from Wesleyan University, and Dr. Clark Wissler from the American Museum of Natural History. Roswell Parker Angier, professor of psychology in Yale University, will act as chairman of the institute.

Ancon's Famous Orchid Garden.—The average visitor to the Isthmus of Panama, on pleasure bent, lands at Cristobal, sees the Gatun Locks, hurries over to Panama, lunches at the Tivoli, is taken in hand by an unimaginative jitney driver, whirled out to the ruins of Old Panama, sees the gold altar, is whisked through Fort Amador and to the train, hustled back to Colon, does a little shopping for things which he could buy better and cheaper at home, rushes aboard his ship and sails away believing he has seen it all. Yet he has not scratched the surface and there remain wonders which he has not even sensed. One of these is the orchid garden on the side of Ancon Hill. Here in a simple little tropical cottage lives Mr. C. W. Powell, one of the most famous orchid growers in the world. He has about seven thousand plants of which over four hundred are indigenous to Panama. For the last fifteen years he has been receiving specimens from Australia, the Philippines, India, China, Mexico, Costa Rica and the various countries of Central and South America. Any visitor is welcome to this garden and this unassuming modest gentleman will exhibit the Flor de Mayo from Colombia, a tree orchid having the general shape of a bell with wings on either side. The centre is white and yellow and the remainder of the flower is a gorgeous purple. He will show the Holy Ghost, a terrestrial orchid, and the famous butterfly orchid of Panama. It is his belief that the orchid represents the highest form of development in the vegetable kingdom, just as man is the highest in the animal kingdom, and he insists that the orchid is not a parasite since it does not live at the expense of its host but by its peculiar anatomy draws from the air, moisture and nitrogen. The seeds grow in pods as long as the middle finger, not unlike artichokes. These pods contain from one to five million seeds of microscopic size and so light that they may be blown about by the softest breeze. Each of these tiny seeds is provided with a rudder somewhat like that of the aeroplane. They will only germinate when they land on a particular fungus and then only after about a year. Growth then proceeds slowly and after a lapse of from seven to twelve years the plant may flower. The orchid is like a banana in that after a bulb sends out a bloom, it dies and another bulb is sent up from the parent root. About ninety-nine per cent. of all orchids are bisexual but cannot pollinate themselves. This is done for them by a small bee which transports the pollen from one flower to another. In Panama the orchids bloom best in March, April and May, but the beautiful Holy Ghost flowers in August. At present Mr. Powell is endeavoring to make this variety come into blossom at Easter tide. In an attempt to do this, he dries the bulbs during the rainy season and waters them copiously during the dry season.

Improved Sanitation at the Port of Callao, Peru.—The newspapers of Lima, of which Callao is the port, have undertaken a campaign for the stimulation of the sanitation of that port. At the present time, steamers and larger vessels do not go to dock but a considerable number of sailing vessels and similar craft load and unload there. Inasmuch as Callao is heavily plague infected and the dock walls form ideal breeding and harboring places for rats, the condition is a considerable menace to other countries. The daily papers are calling attention to the fact that this exercises an untoward effect upon Peruvian commerce as does also the bad general sanitation of Callao itself and are urging that the docks be thoroughly rat proofed and that the town be placed and maintained in perfect sanitary condition. From the viewpoint of the Panama Canal, it is most important that these things be done. The one great epidemic pestilence which threatens the Canal Zone is bubonic plague and could the west coast of South America, particularly the Peruvian littoral, which is the most heavily infected, be freed from this disease, it would be possible to lower some of the restrictions against the free movement of commerce which are now in force.

United States Supplies Trees to Fight Leprosy in Tropics.—The United States Department of Agriculture has supplied the governments of Colombia, Brazil, Venezuela, Ecuador, and Cuba, with large numbers of plants yielding chaulmoogra oil, found useful in treating leprosy. Hawaii, Porto Rico, and the Canal Zone, have also received shipments of the much desired plants and chaulmoogra trees will soon be fruiting widely in tropical America.

Seed for these plants were obtained in the wilds of Siam and Burma during a series of explorations begun in 1920 by the department's plant hunter, J. F. Rock. Chaulmoogra oil is now obtained from India where it is pressed cold and imported at great expense, but experts hope that within ten years tropical America will be supplying its own oil for the cure of leprosy.

During a period of fourteen months ended March 15, 1924, fifty per cent. of the leprosy patients at the Kalihi Leprosy Hospital in Hawaii have recovered and been paroled as a result of chaulmoogra oil treatment, and during the past five years 260 patients have been discharged as cured.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Bowel Atonicity

is a common affliction of faulty diet, advancing years, or the "cathartic habit." The intestinal muscles become sluggish and lose their power, as a consequence of which, the bowel contents are delayed in their passage, over-absorption takes place, and the feces become hardened and reduced in bulk.

In AGAROL COMP.—a palatable, carefully balanced combination of pure mineral oil, agar-agar, and phenolphthalein—the practitioner has a remarkably efficient remedy for correcting the foregoing conditions and permanently restoring the functional activity of the bowel.

As a result of its use, not only, therefore, does Agarol Comp. give remarkable satisfaction as an evacuant, but regularly employed, it soon restores conditions within the intestinal canal essential to its muscular tone and natural activity, and thus enables the bowels, after a reasonable period, to act normally and regularly without further aid or assistance.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbance; not habit forming.

Manufacturing Pharmaceutists since 1856

113-123 West 18th Street New York City

American Chemical Society Activities.—The American Chemical Society at its spring meeting in Washington, D. C., announced its adhesion to the plan for a million dollar national institute for colloidal research. This project has the support of the National Research Council and the National Academy of Sciences, and will be located, it is expected, at the University of Wisconsin. Dr. Edgar F. Smith, provost emeritus of the University of Pennsylvania, presided at the final session of the society's section of chemical education. Sessions were also held by the divisions of petroleum, rubber, agriculture and food, physical and inorganic, sugar, organic and gas and fuel chemistry. A feature of the final session was the presentation of eight papers describing activities of Federal bureaus relating to industrial chemistry.

The amazing expansion of chemistry in this country, now embracing manufactured products valued at $62,000,000,000, demands the adoption of a nation wide system of accident prevention and industrial health, it was asserted in a report of the committee on occupational diseases and hazards in the chemical trades. To devise means of checking inroads upon workers through disease and violence and to prevent extension of contagion to families, a complete survey "without partisan zeal," was urged by the committee, the chairman of which was Dr. Lewis W. Fetzer, of Dallas, Texas. The committee emphasized the advisability of subjecting every applicant for work in a chemical industry to a rigid physical examination. "One of the most difficult tasks in this connection lies in singling out persons who may later prove an industrial health liability," the committee said. "It is here that we have to draw a line of demarcation between diseases or conditions which are primarily caused by a particular line of work and others which are aggravated by the same operation. Periodical examinations of the personnel at frequent intervals will correct much of this. It is the only tangible way of avoiding what would otherwise be costly processes."

A study of health conditions, under the auspices of the United States Public Health Service, was made among 916 chemical workers with respect to earnings. Of these 629 were married men, supporting one or more dependents. The list of diseases of the skin ascribed to occupation is growing, according to the committee, which said that many of the cases are usually mistaken for a nonoccupational eczema. The committee said that instances of dermatoses from coming in contact with the lacquer used on mah jong sets are reported. "The Japanese and Chinese employ a lacquer which comes from Rhus vernis," it was stated. "Contact with either the plant or its extract will cause dermatitis which resembles poison ivy poisoning." Substances used in the dyeing of furs and in cosmetics were given as other sources of poisoning. Match box dermatitis results from contact with matches and the striking surface of match boxes. When zinc oxide, in the brass industry, is inhaled, it sometimes produces, it has been found, a chain of symptoms collectively termed brass founders' ague. Zinc oxide, it was said, daily is receiving greater industrial application, and now is extensively used in the manufacture of paint, compounding of rubber goods, making of linoleum, oilcloth, glass, porcelain, and the preparation of zinc salts.

There is much to be learned about radium, said the report, recording that observations made on the physical condition of persons, male and female, engaged in measuring radium preparations in the bureau of standards here, showed during a period of a year nothing of special significance, though it is known that individuals exposed to large amounts of radiation frequently experience harmful physical results. Chemists, it was declared, are looking forward to early clarity of the situation as to carbon monoxide poisoning. "Poisonings, with fatality," it was said, "have been recorded very frequently from this source during the past year, and much of it has occurred as a result of exposure to illuminating and heating gas and from the automobile exhaust gases." The committee records a notable advance in industrial hygiene in other countries, and urges greater attention to the subject by American chemists.

Pan-Pacific Research Institute Established.—The opening of the new Pan-Pacific Research Institute, which is to be an international establishment for the scientific study of food resources in the Pacific area, has been made possible by the gift to the institution of the Castle home, one of the largest residences in Honolulu, together with four acres of adjacent land. It is expected that this will be the nucleus of a Pan-Pacific University, which has been planned for several years. The organization of this institution will be unique in that it will be truly international. It will be neither American, nor Hawaiian, nor Japanese, nor the property of any other single nationality, but will be governed by scientists from all the countries of the Pacific. The directorship of the institution has been offered to Dr. David Starr Jordan, chancellor emeritus of Stanford University.

Panama Continues War on Narcotic Drugs.—Panama, as the crossroads of the world, is the natural meeting place for all sorts of traffickers in vice and as has been mentioned before in these letters, the situation as regards the sale of the habit forming drugs is always an acute and ever present problem. Recently Mayor Pretelt, of Panama City, adopted the policy of giving persons convicted of engaging in the drug traffic the most severe sentence which the law permits and in the case of foreigners, to deport them on the expiration of their prison sentence. Since they are sent to the penal colony, Coiba Island in the Pacific Ocean, to hard labor, a prison sentence is not altogether a pleasure trip. In the case of Panamans, they are exiled when they have finished a term of jungle labor under the tropical sun. Recently sentences of two years' imprisonment and two years' banishment were imposed on two men and one woman.

A Diagnostic Cancer Clinic in Washington.—The Medical Society of the District of Columbia is planning to open a diagnostic cancer clinic in the Medical Building in conformity with the efforts of the American Society for the Control of Cancer, to impress upon the public the fact that early diagnosis and attention constitute the sole means of combating the disease. This action was brought about largely at the instance of Dr. H. H. Kerr, chairman of the local committee on cancer control.

Homicides and Automobile Fatalities During July.—Figures compiled by the Metropolitan Life Insurance Company, based upon returns from fifteen million industrial policyholders in America and Canada, show that the July death rate from homicide, 9.1 to 100,000 insured, is the highest for any single month on record, with the single exception of October, 1923. Automobile fatalities showed a considerable increase as compared with June, and a rise of more than nineteen per cent. over July of last year. All fatal accidents, considered as a group, increased more than one third over the June figure and also registered a considerable rise over that for July, 1923. Among the industrial policyholders as a whole, however, the death rate from all causes, 8.4 per 100,000, was identical with that for the same month of 1923, and lower than for June, 1924.

Low Death Rate During First Half of Year.—The first half of 1924 has probably registered a lower death rate than was ever experienced for the first six months of any year in the history of the United States and Canada. This is indicated by the mortality records of the industrial policyholders of the Metropolitan Life Insurance Company, as announced by its statistical department which has just completed an analysis of the data.

After an uninterrupted rise for four years, a decline in the diabetes death rate began coincident with the increasing use of insulin in 1923. For the first six months of 1924, the fall amounted to 27.5 per cent. among the white policyholders and to more than ten per cent. among the colored. Although there is, as yet, no positive proof that the reduction is the direct result of the increasing use of insulin, there is reason to hope the phenomena are connected.

The cancer death rate was a little lower than that in evidence at this time last year. The death rate from alcoholism declined slightly. Deaths from acute poisoning by wood and denatured alcohol appear to be decreasing in the industrial population. Fatal accidents showed a little more satisfactory record. The death rates from automobile fatalities continued to increase—only slightly among the whites but about ten per cent. among the colored. There have been fewer suicides.

The typhoid fever rate is still falling and there is promise that a new minimum will be registered in 1924. Diphtheria mortality in the industrial population has been running lower than ever before. Scarlet fever and whooping cough, it is true, show practically the same death rates as for the corresponding period of last year. However, this really indicates improvement, in view of the much greater number of infant lives exposed to risk and covered by the data this year. There has been no general prevalence of epidemic influenza thus far. The mortality from lobar pneumonia decreased markedly among the white policyholders and slightly among the colored. Bronchial pneumonia caused more deaths than during the same period of last year; but this, again, was due to the relatively high number of infants concerned. An increase in the rate for diarrheal diseases is explained on the same ground. The mortality from diseases incidental to pregnancy and child birth declined among white women, but this improvement did not obtain for colored women.

Life Expectancy With Aortic Regurgitation*

FREDRICK A. WILLIUS, M.D.,
and JULIA FITZPATRICK, B.A.,
Rochester, Minn.,
Section on Cardiology, Mayo Clinic

In an attempt to determine as accurately as possible the life expectancy of patients suffering from aortic regurgitation, 463 cases were studied. The observations covered a period of eight years.

Two hundred ninety-six cases (sixty-four per cent.) were nonsyphilitic, while 167 (thirty-six per cent.) were syphilitic in origin. This relationship undoubtedly would be reversed in many localities, yet is proportionate to the general incidence of syphilis as observed in the Mayo Clinic.

TABLE I
NONSYPHILITIC AORTIC REGURGITATION
CARDIAC MORTALITY IN THE COMPLETE GROUP

	Sex			Cardiac deaths					Patients living			
Decade	Total	Males	Females	Patients heard from	Cases	Per cent.	Average time from examination, months	Deaths from other causes	Cases	Per cent.	Improved	Unchanged	Worse

60 to 69	15	12	3	10	5	50	2.9	2	3	30	1	1	1
70 to 79	3	3	0	3	2	67	4.5	1	0	0	0	0	0
Total ...	296	242	54	200	78	39	15.7	27	95	48	39	24	32

In order to avoid misinterpretation, we wish to define clearly the character of the material that forms the basis of this investigation, since groups of similar cases differ in certain respects in various clinics. This is particularly true of the severity of the associated heart failure. The majority of patients with cardiac disease coming to the Mayo Clinic represent a group displaying fairly well advanced involvement. Those with nonsyphilitic aortic regurgitation had the average degree (2)[1] of cardiac decompensation at the time of our examination, while that of the syphilitic group was 2+.

AGE INCIDENCE

The highest incidence of cases of nonsyphilitic aortic regurgitation occurred in the third and fourth decades of life in which eighty-three and seventy-five cases, respectively, are recorded (Fig. 1). It is interesting to contrast this with cases of syphilitic origin, in which the highest incidence occurs in the fourth decade (seventy-four cases). The acquisition of syphilis is notoriously dominant in the second and third decades of life, and as a long latent period, averaging eighteen years (9), elapses from the time of the initial lesion of the disease until cardiovascular symptoms are manifested, the difference in incidence in the two groups is readily explained. There is an abrupt decline in the incidence of aortic regurgitation of both types in the succeeding decades.

SEX INCIDENCE

Our study discloses a marked discrepancy in the sex incidence of aortic regurgitation. In the nonsyphilitic group there were 242 males (eighty-two per cent.) and fifty-four females (eighteen per cent.); a similar ratio occurred in the syphilitic group: 142 males (eighty-five per cent.) and twenty-five females (fifteen per cent.). The infrequency of aortic regurgitation in women was also observed by Gillespie in a review of 2,368 cases of heart disease.

CARDIAC MORTALITY

Seventy-eight (thirty-nine per cent.) of the patients with nonsyphilitic aortic regurgitation died of cardiac disease on an average of fifteen and seven tenths months following our examination (Table I).

Ninety-five patients (forty-eight per cent.) are alive, and thirty-nine report their condition improved, twenty-four unchanged, and thirty-two worse.

The cardiac mortality in the syphilitic group is slightly higher, sixty-three patients (forty-six per cent.) succumbing on an average of fifteen and six tenths months after examination (Table II). Sixty-six patients (forty-eight per cent.) are living, and of these, twenty-seven are improved, fourteen unchanged, and twenty-five worse. It is interesting to note that when the cases are grouped according to

T-WAVE NEGATIVITY IN DERIVATIONS I, II AND III[2]

T-wave negativity in all derivations from heart disease in the electrocardiograms of twenty-two patients, with the nonsyphilitic type of aortic regurgitation, were noted. Six patients (forty per cent) died, an average of fourteen and one tenth months after examination (Table IX). This mortality is contrasted sharply with that of the syphilitic group in which seven (eighty-eight per cent.) of the eleven patients died of cardiac disease after an average of only seven and one tenth months (Table X).

The composite cardiac mortality with significant T-wave negativity in the nonsyphilitic patients was fifty-six per cent. (Table XI), and while considerably higher than the mortality of the complete group, was distinctly less than that accompanying these graphic abnormalities in the syphilitic group in which the cardiac death rate was seventy-six per cent. (Table XII). The higher mortality in the syphilitic group is distinctly in accord with our clinical impressions, as the average patient with syphilitic aortic regurgitation who presents also significant T-wave negativity in the electrocardiogram has more cardiac damage and is distinctly more severely ill than the corresponding patient with the nonsyphilitic lesion. It may be noted that fifty-one per cent. of the syphilitic patients displaying significant T-wave negativity in the electrocardiogram had anginal attacks.

ABERRANT Q. R. S. COMPLEXES IN ALL DERIVATIONS

In the group of nonsyphilitic patients with aortic regurgitation, ten had electrocardiograms with aberrant Q. R. S. complexes in all derivations. Information regarding seven patients was obtained; six (eighty-six per cent.) are dead as the result of heart disease, an average of sixteen and one tenth months after examination (Table XIII). The one patient alive reports his condition as worse. Only one patient of the syphilitic group had this graphic finding, and death occurred from heart disease three days after the examination.

AURICULAR FIBRILLATION

Auricular fibrillation, in our experience, is a rare disorder in aortic disease. It occurred in seventeen cases (six per cent.) of nonsyphilitic aortic regurgitation, and the death of six (fifty per cent.) was attributable to cardiac disease (Table XIV). There were only two cases (one per cent.) in the syphilitic group, and both patients died of heart disease on an average of five and five tenths months after observation.

DELAYED A-V CONDUCTION[3]

Fourteen patients with nonsyphilitic aortic regurgitation had delayed auriculoventricular conduction, the conduction time varying from 0.22 to 0.36 second. Nine (sixty-nine per cent.) died from heart disease twenty-one and three tenths months following examination (Table XV). Only three of the patients with syphilis had this conduction disturbance (0.22 to 0.28 second); two have been traced: one died of heart disease in seven months, and one is worse.

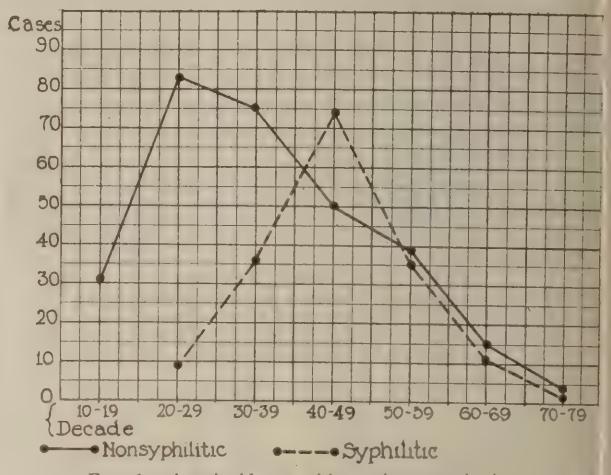

FIG. 1.—Age incidence with aortic regurgitation.

Another group was studied, comprising cases in which the foregoing electrocardiographic disorders were absent. In both the nonsyphilitic and the syphilitic groups, the lowest cardiac mortality was obtained, twenty-four per cent. and thirty-two per cent. respectively (Tables XVI and XVII).

SUMMARY AND CONCLUSIONS

1. Cardiac mortality in the complete group; a, nonsyphilitic aortic regurgitation, thirty-nine per cent., and b, syphilitic aortic regurgitation, forty-six per cent.

2. Cardiac mortality with T-wave negativity in Derivation I; a, nonsyphilitic aortic regurgitation, seventy-six per cent., and b, syphilitic aortic regurgitation, eighty-seven per cent.

3. Cardiac mortality with T-wave negativity in Derivations I and II; a, nonsyphilitic aortic regurgitation, sixty-seven per cent., and b, syphilitic aortic regurgitation, sixty-three per cent.

4. Cardiac mortality with T-wave negativity in Derivations II and III; a, nonsyphilitic aortic regurgitation, forty-four per cent., and b, syphilitic aortic regurgitation, sixty-four per cent.

[3]Delayed A-V conduction not abolished by atropine.

5. Cardiac mortality with T-wave negativity in Derivations I, II, and II; a, nonsyphilitic aortic regurgitation, forty per cent., and b, syphilitic aortic regurgitation, eighty-eight per cent.

6. Cardiac mortality with composite T-wave negativity; a, nonsyphilitic aortic regurgitation, fifty-six per cent., and b, syphilitic aortic regurgitation, seventy-six per cent.

7. Cardiac mortality with aberrant Q. R. S. complexes in all derivations; a, nonsyphilitic aortic regurgitation, eighty-six per cent., and b, syphilitic aortic regurgitation, one case; the patient died from heart disease.

8. Cardiac mortality with auricular fibrillation; a, nonsyphilitic aortic regurgitation, fifty per cent., and b, syphilitic aortic regurgitation, two cases; both patients died from heart disease.

9. Cardiac mortality with delayed A-V conduction; a, nonsyphilitic aortic regurgitation, sixty-nine per cent., and b, syphilitic aortic regurgitation, three cases; two patients were traced: one had died from heart disease; one was worse.

10. Cardiac mortality in cases in which the foregoing graphic abnormalities were absent; a, nonsyphilitic aortic regurgitation, twenty-four per cent., and b, syphilitic aortic regurgitation, thirty-two per cent.

We believe that this study, and previous reports, show that significant abnormalities in the electrocardiogram are attended by a relatively high cardiac mortality, and are of distinct prognostic value.

The Chronic Anemias and Related Conditions*

JAMES H. SMITH, M.D.,
Richmond, Va.

The viewpoint of this paper will be that of the clinic. To keep within limits, physiology, pathology and even some useful diagnostic data will have to be omitted. Doubtless there will appear statements too much condensed to be strictly accurate, but it is hoped they will not be clinically misleading.

So little is known of the etiology of these conditions that any classification must be recognized as tentative. Hodgkin's disease, for example, has been thought to be a form of tuberculosis, has been attributed to a diphtheroid bacillus, and is held by some now to be a variety of sarcoma. Intermediate between the most widely varying blood pictures and clinical types, the gap can be filled by cases representing insensible gradations, leaving in doubt at times the proper classification of a given case. Under such circumstances, one can only aim at the maximum therapeutic benefit to the patient. An example is the following case:

Case I.—Mrs. W. H., aged forty-three, a traveling advertising agent, complained of puffiness about the eyes for two years. There were none of the usual complaints of leucemia. The spleen was not palpable; the liver edge could barely be felt. No evidence of bone tumor could be found. There was no lymphatic enlargement, unless a wheeze over the left hilum indicated bronchial lymph node involvement. The blood picture was as follows: Red cells 5.2 million; hemoglobin 78; color index .75; leucocytes 10,000; polynuclear neutrophiles 35.5 per cent; lymphocytes 27.5 per cent.; large mononuclears 1.5 per cent.; polynuclear eosinophiles 7.5 per cent.; mast cells 2 per cent.; neutrophilic myelocytes 17.5 per cent.; eosinophilic myelocytes 2 per cent.; basophilic myelocytes 1.5 per cent.; myeloblasts 5 per cent. With admirable frankness the report came from the laboratory with the remark: "The more I study this slide, the less I know about it." The patient, under the urge of her craft, left the city with the advice to consult a competent medical man at the first opportunity. If the myelocytes indicated myeloid leucemia, the case presented unusual clinical features and leucocyte count.

The distinction between primary and secondary anemia is not altogether a satisfactory one. The secondary character of an anemia is clear when the cause is known, but chlorosis and pernicious anemia have little in common to justify their being grouped together as primary. I have no intention of suggesting a new terminology, but I think something is gained if primary comes to mean to us prognostic caution, and secondary implies at least an expectation of arriving at the cause. The terms then become guiding principles whether the notion arises out of a study of the blood smear alone or the clinical picture as a whole.

Even when one concludes that he is dealing with a primary anemia, he should not be blind to factors

*Read before the Alleghany County Medical Society at Hot Springs, Virginia, June 13, 1924.

of secondary importance which may tend to offset reconstructive measures.

CASE II.—Mrs. R., aged forty-six; diagnosis pernicious anemia. Two transfusions resulted in a rise of hemoglobin from 50 to 80, red cells from 1.7 million to 3.3 million, with a corresponding improvement in the appearance of the smear and the patient's condition. After two profuse menstrual periods the hemoglobin was 40 and the red cells 1.4 million. Menstruation was stopped by radium, and without further transfusions the hemoglobin rose to 53, reds to 2.5 million and a distinct gain in strength and appearance was noted. Further transfusions will probably have to be employed.

The blood examination often proves to be helpful when least expected. Especially there are a half dozen symptoms and signs which are most often so explained. These are weakness, vertigo, dyspnea and tingling; pallor, palpable spleen, lymph node enlargement, gastric anacidity and certain cord signs. In the presence of these symptoms and signs the main data upon which the ultimate diagnosis is likely to be reached are as follows:

I. ANEMIA

An absolute reduction of hemoglobin and red cells without regard to the ratio between the two.

II. ETIOLOGY

The question of etiology, whether or not a cause is demonstrable. Even though the anemia may have all the earmarks of the Addisonian type, if cancer is present one will usually be inclined to regard the cancer as the cause of the anemia. In fact, rarely are we satisfied to diagnose pernicious anemia without röntgen ray examination for gastric cancer, if this method is available. Of course, there is a long list of conditions which may at times cause severe anemia, but for practical purposes the field may be kept fairly narrow. Syphilis, malaria, tuberculosis and lead poisoning may be frequent causes in certain communities, but I do not think they are in ours. When their presence is characterized by marked blood changes, the cause is not usually difficult to recognize. Neither do I think infected tonsils or abscessed teeth are frequent causes of anemia of this grade, though either may have been the portal of entry for infection of more vital organs. More deserving of emphasis, I think, are slow, prolonged loss of blood, as from hemorrhoids, menorrhagia, cirrhosis of the liver, and peptic ulcer; and such chronic diseases as cancer, nephritis, septic endocarditis or other chronic sepsis, and intestinal parasites. In the last, eosinophilia may be notably absent if the anemia is severe. The presence of a low grade fever throws little light on the type of disease, as it is common to all varieties of advanced anemia. The following are illustrative cases:

FIBROID UTERUS

CASE III.—Miss F. N., aged twenty-eight, single. For six years menstruation, though regular, was profuse. As a result the hemoglobin was 26; red cells 2.7 million; color index 0.5. There was considerable poikilocytosis, polychromatophilia and granular degeneration, but no nucleated forms. Removal of an enlarged, boggy uterus with multiple fibroids resulted in a satisfactory state of health.

A similar case had been diagnosed splenic anemia because the spleen was thought to be palpable and the physician accepted the patient's report of negative pelvic examinations at the hands of three practitioners:

CASE IV.—Mrs. B. N. J., aged thirty-two; hemoglobin 29; red cells 2.9 million; color index 0.5; some poikilocytes, megalocytes and microcytes but no nucleated red cells. It was suggested that the pelvic examination be repeated, with the result that the family physician promptly recognized a fibroid uterus. Hysterectomy was followed by an early return of the blood to normal.

SEPTIC ENDOCARDITIS

CASE V.—T. L. D., male, aged fifty-four. History of weakness for six months, fever, and loss of weight. Temperature 100°; pulse 82; blood pressure 100/50; diastolic murmur at the base of the heart; heart slightly enlarged according to orthodiagram; no embolic nodules; hemoglobin 57 per cent.; red cells 4.2 million; color index 0.69; leucocytes 20,400; polynuclears 93 per cent.; lymphocytes 7 per cent. A diagnosis of chronic septic endocarditis was made. Death followed six weeks later.

HOOKWORM

CASE VI.—Miss V. W., aged seventeen, complained of weakness, vertigo and dyspnea on exertion. Physical examination revealed what was believed to be a congenital heart lesion with considerable hypertrophy. Hemoglobin 22 per cent.; red cells 1.5 million; color index 0.73; considerable microcytosis, megalocytosis and poikilocytes; no nucleated forms; leucocytes 8,200; polynuclears 72 per cent.; lymphocytes 24 per cent; large mononuclears 4 per cent.; no eosinophiles. The feces showed a great abundance of hookworm eggs. The anemia was attributed to these parasites and was overcome by treatment for hookworm.

There are times when one doubts whether his idea of the cause was correct because of the failure of the anemia to respond to treatment directed at removing the cause. At times, of course, there has been an error; but there is, I think, such a thing as a depression of function of important organs, both bloodmaking and others, due to the prolonged anemic condition, in short, a vicious circle, which may make complete recovery very slow even though the primary cause has been removed.

CASE VII.—C. H. B., aged fifty-seven, suffered from what appeared to be a secondary type of anemia though for many months the cause could not be determined. The hemoglobin went as low as 22, and the red cells to 2.7 million. Proctoscopical examination was reported to be negative but later it revealed bleeding hemorrhoids which were regarded as the source of his trouble. In the meantime an intestinal condition not unlike sprue had developed. Removal of the hemorrhoids resulted in slow improvement, but many months more were required before the bowel movements became normal. This latter condition was believed to be due to a depression of pancreatic function, and pancreatin in large dose was used over a long period. The hemoglobin has never risen above 60, but the patient seems to be in very good health.

III. The Color Index

On the basis of a hemoglobin set at 100 and red cells at five million to the c.mm., the normal color index is fixed at 1. Because there is no absolute normal for either hemoglobin or the number of red cells, there is no absolute normal for the color index. However, most severe anemias, other than pernicious anemia, show a hemoglobin reduced out of proportion to the reduction of red cells, with a correspondingly low color index; whereas in pernicious anemia the color index is very likely to be 1 or higher.

IV. The Leucocytes

The number of white cells is apt to be either of very definite diagnostic value as in the leucemias, or of little or no help. A normal or low white count, with a differential count approximately normal or showing only a relative lymphocytosis, is a finding more or less common to all varieties of true anemia. Exceptions may be noted and leucocytosis observed due to pyogenic bacteria, either causative or secondary invaders. Hodgkin's disease, though usually characterized by a leucocyte count approximately normal, may give a leucocytosis between twenty and thirty thousand, with a polynuclear increase. Reference has been made above to the difficulty in classifying certain cases with abnormal blood pictures. Giffin (1) reported a case of persistent eosinophilia with hyperleucocytosis and splenomegaly in a man aged thirty-one, and was inclined to regard the condition as not a true leucemia, though the white cells finally, after splenectomy, rose to 211,000. Polynuclear eosinophiles were present in proportions of fifty-seven to ninety per cent.

ACUTE LYMPHATIC LEUCEMIA

Case VIII.—F. O. S., male, a physician, aged thirty-one, returning from France in 1919, developed lymphatic leucemia of the acute variety, with general lymph node enlargement. The disease ran a course somewhat similar to typhoid fever, and the patient died about six weeks after onset. The leucocyte count ten days before death was 44,500, with 82.5 per cent. lymphocytes and 2.5 per cent. large mononuclears; hemoglobin 40 per cent. Four days later the count was 36,000, ninety per cent. of which were small lymphocytes; hemoglobin, twenty-two per cent.

CHRONIC LYMPHATIC LEUCEMIA

Case IX.—Mrs. J. M., aged fifty-nine, complained of failing vision and progressive weakness and loss of weight. Her oculist reported high intraocular tension, marked iritis, and hemorrhages into the vitreous and retinæ. Iridectomy was done. The tonsils were much hypertrophied. There were hard, enlarged, discrete nodes throughout the neck, in both axillæ some nodes as large as a lemon, and a number of enlarged nodes in each groin. The spleen was not palpable, the liver was felt two inches below the costal border, and hard masses of lymph nodes were palpable in the abdominal cavity. Two weeks later the spleen was felt one inch below the costal margin. Sugar was present in the urine. Blood sugar was 245 mg. to the 100 cc. Leucocytes 928,000; polynuclears two per cent.; small lymphocytes ninety-eight per cent.; hemoglobin 60; red cells 3.6 million; color index 0.83.

Three months later, under x ray therapy by Dr. Fred M. Hodges, and moderate carbohydrate restriction, the patient had gained ten pounds in weight; the spleen was still palpable one inch below the ribs; two fairly largesized nodes were present in the right side of the neck. None were felt in the left side of the neck nor in either axilla. Some were still palpable in each groin. The leucocyte count was 300,000 with no alteration in the differential count. Blood sugar was 215 mg. There was no improvement in vision. In other respects the improvement noted was maintained for a period of six months.

MYELOID LEUCEMIA

Case X.—Mrs. S. T. S., aged forty-two, after x ray therapy had gained ten pounds in weight, presented a splenic enlargement half way to the level of the umbilicus, practically no superficial lymph node enlargement, and the following blood picture: hemoglobin fifty-nine per cent.; red cells 4.2 million; color index 0.69; leucocytes 63,000; polynuclears sixty-two per cent.; mast cells one per cent.; neutrophilic myelocytes nine per cent.; lymphocytes 18.5 per cent.; large mononuclears 7.5 per cent.; basophilic myelocytes two per cent. No report of the condition prior to beginning therapy was available.

V. The Red Cell Picture in the Smear

There is a picture of the red cells in the smear which pathologists recognize as a response of the bloodmaking organs, chiefly bone marrow, to an unusual demand. Immature forms are thrown out into the blood stream like a war worn country calling up its youthful reserves. Some, the normoblasts and megaloblasts, are nucleated; many are misshapen, pearshaped, pointed or having caudal elongations—poikilocytosis; there may be abnormal staining—polychromatophilia; a fine stippling is common. This picture may be approximated in any severe anemia, but it is seen in its completeness in pernicious anemia only. For brevity it will be referred to as the picture of regenerative effort.

VI. The Fragility of the Red Cells

This is observed according to a simple technic. The method in common use consists in observing the point at which hemolysis begins and ends in graduated hypotonic salt solutions. In normal cases hemolysis begins at about 0.45 per cent. and is complete at 0.35 per cent. If it begins and ends earlier resistance is decreased and fragility is greater than normal. In splenic anemia the resistance may be normal but in the hemolytic types is diminished; in pernicious anemia it is usually increased (2).

VII. Splenomegaly

There is no serious derangement of the bloodmaking organs that is not at times accompanied by splenomegaly. The degree of enlargement and the stage of the illness at which it is appreciable are important, but associated signs and symptoms are more so. In splenic anemia and in myelogenous leucemia, splenomegaly is apt to be an outstanding feature, both as to size and early appearance. In lymphatic leucemia the spleen is as a rule palpable but not greatly enlarged. In Hodgkin's disease the enlargement is not often very gross, and in the majority of cases the organ is not palpable; and the same statement will hold in pernicious anemia. In secondary anemias the spleen can often be felt, but it is usually

when the primary cause, such as malaria, syphilis and septic infection, may be in itself a cause of splenomegaly without grave anemia.

VIII. Liver Enlargement and Jaundice

In the leucemias the liver is, as a rule, enlarged, more grossly in the myeloid than in the lymphoid type. In pernicious anemia it is palpable rather more frequently than is the spleen, but hardly in more than one third of the cases. In Hodgkin's disease it is less frequently felt than in the leucemias or in pernicious anemia. In the more advanced stages of splenic anemia it becomes grossly enlarged. Jaundice is not common to the conditions under discussion, but may occur in any of them. It is the conspicuous feature of congenital or familial hemolytic jaundice, and a prominent feature of the acquired type of this affection.

IX. Lymph Node Enlargement

Along with the bone marrow, the spleen and the lymph nodes are functionally associated with blood formation and destruction. Though generalized adenopathy may occur in any of the anemias and leucemias, it is distinctly most prominent in lymphatic leucemia and Hodgkin's disease. There is a somewhat characteristic grouping like a bunch of grapes, and a brawny feel to the lymph nodes when involved in Hodgkin's disease. At times in the early stages of either lymphatic leucemia or pseudoleucemia, the superficial nodes fail to show enlargement. Enlarged mesenteric nodes may then be palpable, but röntgen ray examination of the mediastinum is a more fruitful line of investigation. When a superficial node is accessible, excision and microscopical examination may serve to distinguish Hodgkin's disease, sarcoma of different types, tuberculosis, lymphatic leucemia or syphilis.

A case offering diagnostic difficulty due to the absence of superficial lymph node enlargement, showed a hemoglobin of fifty per cent.; red cells 3.7 million; color index 0.6; leucocytes 26,400; polynuclears eighty-one per cent.; lymphocytes seventeen per cent.; eosinophiles two per cent. The spleen was palpable about two fingerbreadths below the costal margin. Röntgen ray report described "along the right border of the heart and aorta several discrete, more or less round, areas of density. These are near the sternum in front, the largest ones being close to the hilus area, and varying from a little more than an inch in diameter to about a half inch; with two similar areas to the left of the sternum opposite the second interspace." This report, in conjunction with the leucocyte count and splenomegaly, were interpreted as Hodgkin's disease, though the opportunity was not afforded to confirm the diagnosis microscopically.

A more classical picture of Hodgkin's disease was the following:

Case XI.—A. C., male, aged eleven. A month prior to admission cervical nodes began to enlarge, followed by abdominal swelling. Conglomerate brawny masses of nodes bulged on both sides of the neck, and were palpable in the axillæ and the groins. The abdomen was much distended, but the spleen could be outlined as more than filling the left upper quadrant. Hemoglobin was sixty-three per cent.; red cells four million; color index 0.75; leucocytes 8,400; polynuclears forty-two per cent.; lymphocytes fifty-six per cent.; mast cells two per cent. Death ensued a few months after the date of the record—April 6, 1917.

Longcope (3) and others have described under the term infectious mononucleosis or glandular fever a selflimited, febrile illness, characterized by general enlargement of the superficial lymph nodes, usually a palpable or moderately enlarged spleen, and a leucocyte count ranging from ten to twenty-six thousand, with the proportion of mononuclears from fifty to ninety-five per cent. These cells include, in addition to the small lymphocyte and large mononuclear cell of normal blood, a cell somewhat intermediate in size, with oval, kidney shaped or slightly lobulated nucleus, and a nongranular, basophilic protoplasm. The condition most nearly resembles acute leucemia, but differs in the early and marked enlargement of the lymph nodes, the absence of anemia and purpura, and the abnormal mononuclear cell referred to.

X. Gastric Anacidity

A total absence of free hydrochloric acid is perhaps the most constant finding in pernicious anemia. It is less influenced by periods of remission than is the blood picture. Its constancy would seem to offer a hopeful clue to investigators seeking an understanding of the etiology and essential pathology of the disease. We should not infer, however, that anacidity in an anemic patient establishes the diagnosis of pernicious anemia. Hurst and Bell (4) present interesting figures, reporting complete achlorhydria in four per cent. of one hundred normal individuals; 14.8 per cent. of sixty-three cases of various medical diseases; ninety-six per cent. of sixty-six cases of pernicious anemia; thirty-three per cent of ten cases of carcinoma of the stomach; one hundred per cent. of eight cases of subacute combined degeneration of the cord (which they consider to be due to a neurotoxin associated with the hemolytic toxin of pernicious anemia); in eleven per cent. of nine cases of tabes dorsalis; and in none of eight cases of disseminated sclerosis.

It is possible one occasionally may diagnose pernicious anemia without achlorhydria, but it is quite certain, on the other hand, that severe secondary anemias also may be associated with alchlorhydria, and without doubt would show as high a percentage of this gastric abnormality as the series of various medical cases quoted above, 14.8 per cent. There is reason to think the red, sore, excoriated tongue, as well as the diarrhea sometimes seen in pernicious anemia, is closely associated with lack of gastric acidity.

Blood Picture Suggestive of Pernicious Anemia without Achlorhydria

Case XII.—G. A. G., male, aged fifty-nine. Hemoglobin forty per cent.; red cells 1.8 million; color index 1.1; leucocytes 3,400; polynuclears thirty-seven per cent.; lymphocytes sixty-two per cent.; eosinophiles one per cent. The smear showed the presence of microcytes, megalocytes, poikilocytes, polychromatophilia, and one megaloblast to the one hundred leucocytes. In the gastric contents after the Ewald meal, free hydrochloric acid 5 in forty-five minutes, 23 in sixty minutes, and 34 in seventy-five minutes. Neither the spleen nor the superficial

lymph nodes were enlarged. Four abscessed teeth were reported on the basis of x ray films. Slight hemorrhoids present did not appear to have been the source of blood loss. We felt doubtful of a diagnosis of pernicious anemia on account of the gastric acidity, though transfusion was done and the abscessed teeth extracted. The hemorrhoids also will be removed.

A more typical case of pernicious anemia is the following:

CASE XIII.—C. G. B., male, aged sixty-six. Hemoglobin forty per cent.; red cells 1.8 million; color index 1.1; microcytes, megalocytes, poikilocytes, polychromatophilia, granular degeneration and an average of one megaloblast to the slide; leucocytes 3,400; polynuclears forty-two per cent.; lymphocytes fifty-five per cent.; eosinophiles three per cent. Neither the spleen nor the liver was palpable; no enlargement of superficial lymph nodes. Gastric contents showed no free hydrochloric acid. Röntgen ray studies of the gastrointestinal tract by Dr. A. L. Gray were negative. There were signs of cord degeneration, but pertaining more to the posterior than to the lateral tracts. Though the blood Wassermann reaction was negative, lumbar puncture was advised but declined. Under a single series of two transfusions the general condition remained satisfactory for a period of a year, as represented by a hemoglobin of eighty-five per cent.

BLOOD PICTURE OF SEVERE SECONDARY ANEMIA WITH ACHLORHYDRIA

CASE XIV.—Mrs. A. D. L., aged forty. She had had three miscarriages, the last six months prior to date when first seen. Wassermann and clinical evidence of syphilis were negative. There was no unusual loss of blood. She had two abscessed teeth. Hemoglobin was thirty per cent.; red cells 2.4 million; color index 0.6; leucocytes 4,600; polynuclears seventy-one per cent.; lymphocytes twenty-four per cent.; large mononuclears four per cent.; eosinophiles one per cent. Free hydrochloric acid absent in three specimens taken at intervals of forty-five to seventy-five minutes after Ewald meal. The abscessed teeth were extracted but the condition was attributed also to other depleting causes, including the history of miscarriages. Under treatment with hydrochloric acid, iron and arsenic, her condition became practically normal within a year and has remained satisfactory during the succeeding five years.

XI. SPINAL CORD CHANGES

Evidences of a combined subacute degeneration of the cord affecting the posterior and lateral columns are likely to arise in pernicious anemia, though often late. The upper extremities are most often involved but the lower not infrequently. The neurological signs may precede the development of the characteristic blood picture, but rarely, if ever, do they develop prior to achlorhydria. The cord changes may be progressive in spite of general well being.

CASE XV.—Miss E. S., aged forty-three, April, 1921. Hemoglobin forty-five per cent.; red cells 1.9 million; color index 1.2; leucocytes 3,000; polynuclears sixty-five per cent.; lymphocytes thirty per cent.; large mononuclears four per cent.; eosinophiles one per cent.; free hydrochloric acid absent. Neurological examination negative. She was transfused and sent home, taking hydrochloric acid and arsenic. She returned in June, 1923. From the blood examination alone the diagnosis of pernicious anemia could not have been made. Achlorhydria, however, was still complete and the neurological condition was as described in the following note of Dr. Beverley R. Tucker: "Neurological examination shows knee jerks present and equal; Achilles jerks absent; no Gordon; no ankle or patella clonus; double Babinski; no Oppenheim; muscle power lowered; muscle tone increased; no adiadochocinesia or ataxia; sense of position is poor; no tremor of the fingers, face, tongue or muscles; areas of hyperesthesia, partial loss of postural sense in both lower limbs; is unable to recognize heat in both legs; thighs, trunk, arms, etc., normal; no speech changes; pupils are dilated in size, slightly irregular in shape, react sluggishly to light and promptly to accommodation; slight nystagmus, no diplopia, ptosis or exophthalmos; fundi negative except for pigmented deposit in the right disc; cranial nerves are negative except for slight right facial weakness and possible involvement of the vestibular, intermediate, glossopharyngeal and optic." Vibratory sense was lost in the lower extremities and sacral region; normal in the upper extremities and sternum (Dr. Finley Gayle).

SUMMARY

On the basis of the foregoing analysis of symptoms, the different clinical pictures may now be reconstructed in brief outline.

Chlorosis is a disease of girls and young women, characterized by pallor, menstrual irregularities and digestive disturbances, a distinctly low hemoglobin and low color index, without other marked abnormality of the blood picture, lacking the causal factors of secondary anemia, and usually responsive to the administration of Blaud's mass. As students many of us may have gained the impression that it is a common disease. As a matter of fact it seems to be comparatively rare.

Severe secondary anemia is characterized by a low color index; if there are evidences of the regenerative effort on the part of the bone marrow, it is only in the more profound cases and then not so marked as in the primary types; and an adequate cause is usually demonstrable.

Pernicious or Addisonian anemia usually gives a high color index; the regenerative effort is marked; the red cells are not fragile, their resistance being increased; there is no demonstrable cause of the anemia; free hydrochloric acid is nearly always absent from the gastric contents; cord changes are likely to develop; subcutaneous fat is well preserved, and there is a somewhat characteristic lemon yellow pallor to the skin. There is a tendency to remissions.

Aplastic anemia is usually regarded as a form of pernicious anemia in which there is a steadily falling white and red count with little or no sign of regenerative effort or tendency to remission.

In myelogenous leucemia splenomegaly is a prominent feature, and the excessively high white count, from thirty to several hundred thousand, is chiefly made up by granular cells, with many myelocytes.

In lymphatic leucemia, lymph node enlargement overshadows splenomegaly; leucocytosis is equally as

prominent as in the myeloid form, but the cells are lymphocytes, usually small and mature in the more chronic form, large and immature in the acute form.

Hodgkin's disease, or pseudoleucemia, often has a more distinctive glandular enlargement, especially in the cervical region, than is seen in lymphatic leucemia; the total leucocyte count is not above 30,000, and usually within the normal or near normal range, including the differential count. The anemia is of the secondary type, and an excised lymph node is likely to show a definite pathology.

Splenic anemia offers few positive features, and the diagnosis is arrived at chiefly by exclusion. Except for a secondary type of anemia, the blood picture is essentially normal, barring intercurrent infections. The spleen enlarges early and is often larger than in any other condition, except myeloid leucemia. It is distinctly chronic. There is no demonstrable cause. There is a marked tendency to hemorrhage. Its title to recognition as a disease entity is doubtful. In its most frequent form it is now regarded as an early stage of Banti's disease, enlargement of the liver and ascites representing later developments. In this type resistance of the red cells is usually normal.

Gradually there have been separated off from the group of splenic anemias more or less well defined subvarieties (2), namely, Gaucher's disease, von Jaksch's disease, congenital and acquired hemolytic jaundice.

Only about twenty authentic cases of Gaucher's anemia have been reported. It begins in infancy or childhood and pursues a chronic course, averaging twenty years. The spleen may become larger than in any other disease. It has rarely been diagnosed except at autopsy, where characteristic large, vesicular cells with small eccentric nuclei are found blocking the sinuses of the spleen and lymph nodes or crowded in the capsule of the liver lobules.

Von Jaksch's disease occurs in infancy, one to two years of age, is characterized by splenomegaly, and is usually associated with rickets.

Jaundice, nonobstructive, hemolytic in origin, rare in Banti's disease, is characteristic of the two remaining types. If it is congenital or familial, the patient is likely to seem more jaundiced than sick; in the acquired form the patient is distinctly more anemic and sick than jaundiced (Chaufford). The resistance of the red cells is diminished. There is splenomegaly. The liver is often moderately enlarged.

THERAPY

General reconstructive measures are applicable in all the conditions discussed. The most nutritious and assimilable diet, iron, arsenic, fresh air, and a generally good hygiene are, of course, important. If bleeding is intractable or the clotting time prolonged calcium chloride or serum applied locally or subcutaneously may be used.

In chlorosis the diagnosis should be questioned if the response to iron in the form of Blaud's mass is not reasonably prompt and complete.

The treatment of secondary anemia obviously will vary with the cause. Transfusion as an adjunct should be borne in mind.

In pernicious anemia transfusion holds a place of prime importance. My associate, Dr. Williams, uses whole blood by the syringe method of Linderman, and repeats the process as often as may appear necessary. The reactions seem less severe and the benefit more striking than with the citrate method. Usually from two to three transfusions are made within the first one or two weeks. Within the past three years we have only rarely had to repeat the series of transfusions. Most of the patients are in reasonably good health, though distinctly below normal. Needless to say we do not imagine that any patient is permanently cured, and are conscious of the natural tendency of the disease to remit. Dilute hydrochloric acid is given continuously in an average dose of one drachm three times a day. Neurological symptoms are treated by hydrotherapy, massage and exercise, but without any striking benefit. Hurst and Bell emphasize the importance of eradication of foci of infection about the mouth and elsewhere, believing that the achlorhydria permits pathogenic bacteria to pass into the intestinal tract in viable form. In fact, on this they base their ideas of the etiology of the disease. The obvious importance of relieving the patient of further drain through menorrhagia, bleeding hemorrhoids and the like, need not be emphasized. Splenectomy, I think, is not advocated as much as in the past. Germanium dioxide has not fulfilled its promise.

Röntgen ray therapy or radium, I think, is the most useful palliative measure in the leucemias and in Hodgkin's disease. The choice depends upon the material equipment and personal experience of the operator, with whom must be left the dose, frequency and sites of application. The method is not without acute dangers. It is to be hoped that increased benefit may be had with the high powered machines recently developed. The myeloid form of leucemia appears to be more amenable to ray therapy than the lymphatic type. The same is true of benzol, which has been found effective in reducing the cell count and improving the general condition of leucemic patients. The dose varies from five to twenty or more drops three times a day and should be stopped before the count reaches normal (5). Splenectomy may be advisable following röntgen ray or radium treatment in myeloid leucemia. In Hodgkin's disease salvarsan has been advocated, but has not gained for itself any established place. I have used it without apparent benefit.

In splenic anemia, at least in Banti's disease and the hemolytic jaundice types, splenectomy, done early, has given excellent results.

The Rationale of Acute Mercuric Chloride Poisoning

*A Simple Method for Its Treatment**

A. E. OLIENSIS, M.D.

Philadelphia

Associate Professor in Medicine, Temple University Medical School, Visiting Physician, Samaritan Hospital, Assistant Visiting Physician, Philadelphia General Hospital

In approaching the subject of acute mercuric chloride poisoning we are confronted with a mass of apparently contradictory evidence derived from clinical observation and laboratory experiments. For clinical study we have the outstanding results of Lambert and Patterson, and Weiss; on the side of laboratory research we have most prominently before us the studies of MacNider, and Sansum, and the work of Haskell, Carder and Coffindaffer. The difficulty is to harmonize their apparently contradictory conclusions. According to Sansum (1) all efforts to effect a cure by diuresis, when once absorption of the minimum lethal dose of mercuric chloride has taken place, are futile. This he has amply proved by experiments with dogs, experiments so carefully controlled as to be incontrovertible. He tested out all known methods of treatment only to find them unavailing. His conclusion is that only by prevention of absorption can anything be accomplished in cases of mercuric chloride poisoning. In his experiments he used the intravenous method for administration of the mercury. On the other hand, Haskell, Carder and Coffindaffer (2) in experiments also carefully controlled but administering by mouth the lethal dose (proved to be so by controls of untreated animals) found that by forcing large quantities of salt solution parenterally, twenty out of twenty-five dogs were saved.

What then is the explanation of these to all appearance diametrically opposite results? It is here that MacNider's (3) work on the relationship of acidosis to acute mercuric chloride intoxication steps in and reconciles their conflicting views. MacNider believes that the excretion of mercury is not in itself the important factor in the production of nephritis, but that the accompanying acidosis is responsible.

The renal pathology has been shown by MacNider (4), and this has been confirmed by other observers (5), to consist of swelling of the epithelium of the convoluted tubules, followed by necrosis, fatty infiltration of the tubules of the loops of Henle and acute congorgement of the glomerular vessels. The kidney is swollen; the capsule is tense and constricts the bloodvessels. It is manifestly unreasonable to expect the kidney so involved to function normally. Far less will it be able to do the extraordinary work which devolves upon it in acute mercuric chloride poisoning. Burmeister and McNally (6) have, moreover, shown that mercury can be found in the blood of dogs ten minutes after its ingestion. Therefore, we feel that, while efforts should be made to administer antidotes and to remove by mechanical means as much as possible of the drug from the gastrointestinal tract, we shall, in practice, never have the opportunity to establish treatment soon enough after the dose has been taken, to place reliance upon this procedure. We must, therefore, have recourse to other measures if we are to hope for success in controlling this poison.

We believe that the unfavorable results obtained by Sansum after administration of the minimum lethal dose, in spite of his using all known forms of treatment, may be accounted for in two ways:

1. The lethal dose was given intravenously, thus at once establishing an acidosis which caused irreparable damage to the tissues of the body before any mitigating agent could be introduced. It has been shown that the slightest change in the reaction of the blood is incompatible with life and that an increase of the hydrogen ion concentration of the blood to one gram in ten million litres, causes immediate death. Thus, just as it would be expecting too much from diphtheria antitoxin or tetanus antitoxin to effect a cure when administered late in the disease, so it would be expecting too much from alkali to obtain reconstruction of the damaged tissue either in a prolonged or in a very severe case of acidosis. MacNider (7), however, did show that he was able to inhibit the toxic action of uranium nitrate by means of sodium carbonate, provided acidosis was not already established.

2. The kidney, already crippled, was subjected to further injury in being forced to excrete large quantities of water.

We shall find, proceeding from the same premises, an explanation of the favorable results obtained by Haskell, Carder and Coffindaffer (2) who administered the minimum lethal dose of mercuric chloride by mouth, and, by parenteral injection of large quantities of salt solution were able to save twenty out of twenty-five dogs. The reasons for their success were:

1. Because the mercuric chloride was administered orally, the absorption into the blood was more gradual, so that treatment could be instituted before irreparable acidosis was established.

2. The salt solution tended to prevent the mercuric chloride from establishing an acidosis. We believe that their results would have been even better had they used the same quantity of alkali with a smaller volume of fluid.

Mercury is known to be excreted by all the emunctories—by the lower bowel, through urine, saliva, and sweat, but especially by the lower bowel and the kidney which, as has been indicated, would be in no condition to cope with this task. In view of this state of affairs, we feel that our efforts should not be in the direction of pushing the crippled kidney to more than its usual share of work, but that we should endeavor to spare it even to the extent of limiting the fluid intake.

To us, the treatment of acute mercuric chloride cases resolves itself into the following indications:

*Read before County Medical Society, Philadelphia, June 11, 1924.

1. To eliminate by mechanical means as much of the mercury as possible from the gastrointestinal tract.

2. To institute methods to prevent the establishment of a severe acidosis.

3. To spare the kidney.

4. To accomplish these results in the simplest possible manner and with least disturbance to the patient.

The first indication was simple, and the usual means were employed. The patient was put to bed, milk and white of eggs given, and gastric lavage ordered.

The second indication, i. e., protection against an existing or impending acidosis, was less simple, but we came upon a successful solution of this problem by accident. You will recall that in many cases of influenza during the epidemic of 1918 acidosis and nephritis were dominant factors. Upon the suggestion of Dr. W. E. Robertson, we put those patients on twenty grains of potassium citrate and thirty grains of sodium bicarbonate, three times a day for the average adult, and employed simultaneously the other measures usual in combating acidosis, such as Fischer's solution by enteroclysis. This method proved to be successful in the influenza cases, and since they bore a striking resemblance to cases of acute mercuric chloride poisoning, we decided to use the identical method in combating the acidosis set up by mercury.

The third indication, i. e., to spare the kidney, was put into effect by limiting the fluid intake to such quantity only as would suffice to allay the patient's thirst. Salt was excluded, though the diet was not absolutely salt free, and meat and eggs were interdicted; otherwise the patient was encouraged to eat sufficient food to satisfy his appetite. Sufficient magnesium sulphate was given to secure two bowel movements daily. At first, however, owing to the irritation of the mercury, the bowels take care of themselves. Hot packs were applied daily.

SUMMARY OF TREATMENT

1. Patient is put to bed. One quart of milk and the whites of three to four eggs are introduced into the stomach. Gastric lavage.

2. Potas. citrate, gr. xx } t. i. d.
Sod. bicarb., gr. xxx }

3. Fischer's solution, oz. vi, as retention enema twice daily.

4. Hot pack daily.

5. Soft diet, limit salt; no meat, no eggs; milk, oz. viii, every third hour.

6. Water in quantity sufficient only to satisfy thirst.

7. Magnesium sulphate every morning in dose sufficient to secure two stools daily.

The treatment of acute mercuric chloride poisoning, as outlined above, was instituted at the Samaritan Hospital in December, 1918, and has been in use to the present day. Of the fourteen cases treated during that time, one terminated fatally. In this case the treatment could not be applied because the patient had severe gastroenteritis. He had swallowed fifteen seven and a half grain tablets dissolved in water and was brought to the hospital in a state of collapse, vomiting and purging blood. The usual amount of mercuric chloride taken was fifteen grains, although we had one patient who had taken seventy-two grains, and in the fatal case the patient had ingested one hundred and eight grains. Treatment was usually instituted from ten minutes to two hours after ingestion of the poison.

Since this treatment has been inaugurated and proved to be almost invariably successful, our attitude toward these cases has undergone a radical change. A sense of helplessness and fatalism has given way to one of optimism and confidence; and we now feel that, unless a primary gastroenteritis causes a fatal termination, no case is absolutely hopeless.

A Case of Gonorrheal Arthritis with Purulent Fluid in the Synovial Space

MIGUEL LAVANDERA, M.D.,
New York
Assistant Attending Urologist, French Hospital

The remarkable cures in twenty-seven cases of gonococcal arthritis reported by Ballenger and Elder (1), prompt me to report the following case:

Case.—A naval officer, aged thirty-eight, South American, single, entered the French Hospital October 15, 1923, because of great pain in the right knee joint and inability to use the extremity. Eight years ago he had gonorrheal urethritis, lasting several weeks under medical care. Three days after exposure, five weeks ago, he manifested urethral discharge, painful and frequent urination, for which he received daily thermoelectrical treatment and patent injections for the next thirteen days. He then sailed for this country, the trip lasting fourteen days, during which time a severe acute inflammation of the right knee gradually developed. For the relief of pain the doctor on board applied "hot applications" to the knee.

Physical examination.—The patient was muscular and well developed. The right leg was held semiflexed, the knee abducted, swollen, red, hot, tender on pressure or motion. By rectum the prostate and vesicles were not enlarged or painful.

Laboratory findings.—White blood cells 8,000; lymphocytes, 12 per cent., small mononuclears 5 per cent., polynuclears 83 per cent. Two cultures of the

aspirated synovial fluid on two occasions were full of pus but sterile. Expressed secretions from the prostate and vesicles contained considerable pus and several colonies of intracellular and extracellular diplococci. The urine was negative except for a few pus cells. Blood Wassermann was negative.

Course and treatment.—October 19th, four days after admission, an accumulation of fluid in the synovial space became evident by marked fluctuation, increased swelling and pain. From now on aspiration and injection of the synovial fluid, according to the procedure of Ballenger and Elder, were begun.

October 26th, the synovial fluid having changed from yellow to dark green, the pain and swelling unrelieved, incision and drainage of the synovial space were considered, though decided against for further observation.

October 28th, after the fourth injection, relief from pain and swelling was appreciable. Thereafter gradual improvement continued. The number of injections was six; the dose of each injection averaged forty-three cubic centimetres, the injections exciting no reaction. The temperature ranged from 99° to 101° F., from time of admission to November 9th.

November 6th, however, the patient was allowed out of bed and walked with the aid of crutches. Massage of the prostate and vesicles, followed by bladder and urethral irrigation, was begun and continued twice a week till the patient was discharged cured.

November 14th the patient discarded the crutches for a cane.

November 18th the patient was discharged from the hospital and resumed his daily work, though the knee still presented considerable induration, while motion in the joint was limited to forty degrees. Slight pain on motion.

February 15th, four months following admission to the hospital, the patient was discharged cured, with some induration still present in the soft parts surrounding the joint.

COMMENT

In this case, typically one of acute gonorrheal arthritis, the patient was in excellent general condition and being treated as outlined above should have been relieved and cured as promptly as were the patients in the twenty-seven cases of Ballenger and Elder, some of whom were reported to have been relieved in twenty-four hours, while nearly all the cases were said to be cured in about two weeks' time.

Since almost all cases of gonorrheal arthritis follow prostatitis and vesiculitis, it is rather difficult to explain, on grounds of immunity or virulence, the great difference in the response to treatment between the cases referred to and the one described above. It must be emphasized, however, that in the case under discussion the patient was greatly benefitted by the synovial fluid injections. Had the synovial space been incised and drained, the result would probably have been at least partial ankylosis of the knee joint.

As exercise for the joint involved, voluntary motion sufficed in this case.

Acute Empyema Treated by the Combined Closed and Open Method*

W. B. MARBURY, M.D.,
Washington, D. C.

In reviewing the literature of empyema since the influenza epidemic of 1918 it is interesting to note the many variations in treatment. Hardly any two surgeons seem to use the same method throughout. Many of the articles are written avowedly in the interest of some new technic or appliance, some of which have marked a real improvement in the handling of these cases; others have done little more than to increase the already voluminous literature on the subject. This shows that the results have not been ideal, but the continual striving at least redounds to the glory of the profession.

Before the epidemic of 1918 practically all cases of frank empyema were treated by either rib resection of intercostal thoracotomy, and the mortality ranging around twenty-eight per cent. was accepted as more or less inevitable.

During the war, among the soldiers in camp, the mortality rose to between fifty and seventy-five per cent. in some series. This was hardly considered good enough, and those in charge of the medical affairs of the army began to take inventory. An Empyema Commission was formed by which Dr. Allen B. Kanavel took charge. At that time there were 980 cases of empyema in the Army Hospital. The difference in the mortality per cent. between this and ordinary times was due to the difference in the kind of organism operating. Empyema occurring in civil life was generally secondary to pneumonia and the organism found was the pneumococcus. During the epidemic, empyema more frequently accompanied bronchopneumonia or measles, and the prevailing organism was streptococcus and less frequently staphylococcus. We are not concerned here with the tubercle bacillus except as a complication.

It is important to understand the modus operandi of these different organisms. Empyema as a complication of pneumonia frequently is not demonstrable until after the acute stage of the former disease is past. The temperature may drop to normal and remain so or show remissions for several days. The involvement of the pleura may be due to rupture

*Reported before the Medical Society of the District of Columbia, April 16, 1924.

of a subvisceral abscess, as given by Ransohoff as the most frequent cause of empyema. On the other hand, when streptococcus or staphylococcus is the offending organism, the involvement of the pleura is early and shares in the general pulmonary infection. The endocardium and peritoneum may also

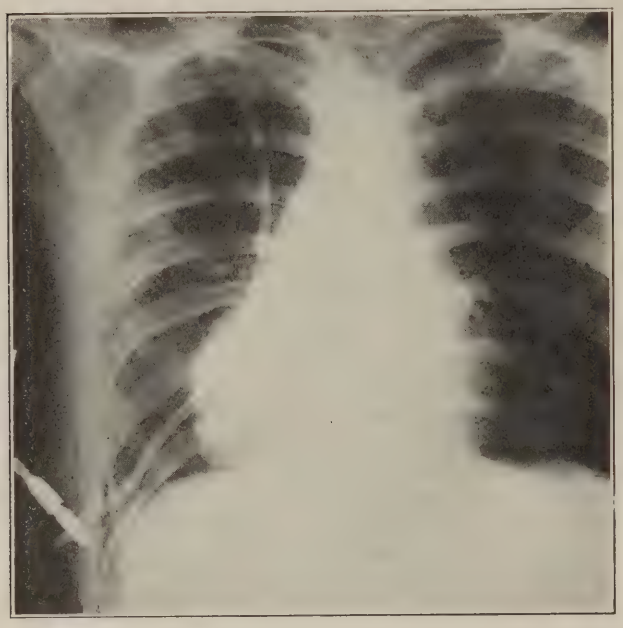

FIG. 1.—Case III, J. C. Shows expansion of lung while negative pressure in the pleural cavity was maintained. The tube is inserted further than necessary.

be involved. If we accept the theory of the subvisceral abscess gradually extending to the periphery and finally breaking into the pleural cavity, we can see why empyema following pneumonia may be localized or even interlobular. The parietal and visceral pleura are prepared by the slowly extending infection and have a chance to wall off the invasion much as the peritoneum does in spreading infection from an appendix. Compared with this the infection of the pleura by streptococcus or staphylococcus is like a blow between the eyes. No chance is given the pleura to wall off the invasion and the infection is of such a nature that few or no adhesions are formed until the third week, granting that the patient lives that long.

Eggers reports two series of cases showing the difference in virulence of the streptococcus and pneumococcus. In the first there were sixteen cases of streptococcal origin with a mortality of sixty-two per cent., and in the second there were fifty-three cases with a mortality of 5.5 per cent. Again, in the first series there were fifty-four cases of pneumococcal origin with a mortality of seventeen per cent., and in the second seventeen cases with a mortality of 5.8 per cent. In the streptococcal cases the hemolytic type greatly predominated. It would seem from this that the mortality from streptococcus may vary greatly, i. e., from sixty-two per cent. in the fulminating cases associated with measles, to 5.6 per cent. He reports six autopsies, all of which showed infection of the endocardium, pericardium, or peritoneum.

Some interesting experiments have been done by Graham and Bell on dogs showing the effect of an open pneumothorax. They demonstrated that where the mediastinum is not anchored by adhesions, given an open pneumothorax on one side, it will deviate to the other side and so compress the lung of the socalled unaffected side that the pressure on the two sides will be equalized. As Kanavel puts it: "If we speak of the affected side and the sound side we are deceiving ourselves, for the compression of the two lungs is approximately equal, and the conception of one lung working without let or hindrance in spite of an extensive pnuemothorax on the opposite side, is erroneous." The actual difference in pressure on the open and closed sides will be less than one cm. of water. In other words, if positive air pressure is made in one pleural chamber equal to ten cm. of water, the pressure in the other chamber will be between nine cm. and 9.5 cm.

They also emphasized the importance of the relation between the size of the opening in the chest and the tracheal inlet and showed that when the former approached the latter, when the vital capacity was greatly reduced, the competition between the two may become so keen as to endanger the life of the patient. Air will enter through the portal of least resistance and if the chest wound is large, so little air will enter the lungs as dangerously to limit the vital capacity, in spite of the increase in rate and amplitude of respiration.

A homely but applicable analogy can be drawn between this condition and the endeavor to suck water from a glass with one straw on the inside and the other on the outside. If the lumen of the two straws are equal, little or no water will be sucked up, but if the one on the outside is smaller, the

FIG. 2.—Case III, J. C. Shows lung contracted due to leakage of air after multiple incision had been made to drain subfascial abscess

amount obtained will be in proportion to the difference in their calibers. We all have seen the socalled sucking wound, caused by the penetration of the chest by large shell fragments, and the distressing dyspnea and cyanosis that resulted. Simply suturing the skin over these wounds, or, where this was im

possible, slapping a large wet dressing over them, gave almost immediate relief.

It might be well to pause here for a moment to inquire into the reason why a patient, in the early stages of empyema when the lung and mediastinum are not stabilized by adhesion, or even fairly late

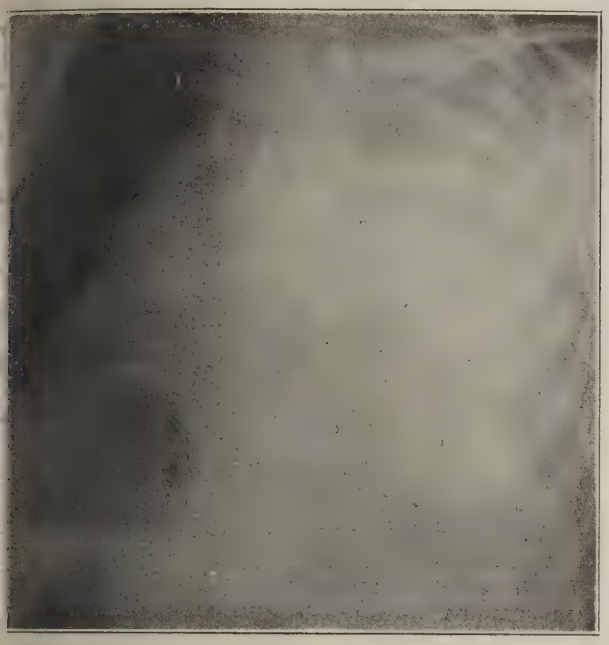

Fig. 3.—Case VII, E. P. Massive empyema of the right pleural cavity.

when the infection is due to streptococcus and few or no adhesions are formed during the first two weeks, should stand so poorly even a comparatively small opening into the pleural cavity.

Hutchinson in 1846 by the use of a spirometer showed that the vital capacity, i. e., the greatest amount of air that can be expired after the deepest possible inspiration, in the average man is about 4,500 c. c. and that the "tidal air," or what we actually use in breathing, is 500 c. c. The difference between these two is made up by the complementary and supplementary air. Lately it has been shown that this estimate of the vital capacity is too low and that a man six feet tall will have a vital capacity of 4,800 c. c. It is not hard to understand then that the nearer the vital capacity approaches the tidal air the smaller will be the margin of safety, and if at any time it becomes less, the result will be asphyxiation and death. Now when we realize that the lungs have no inherent power to expand but admit air only because the respiratory muscles of the chest and the diaphragm cause the chest to expand and produce a partial vacuum within the pleural cavities, it is easy to see why this relative vacuum is necessary.

Graham has shown that the amount of dyspnea that follows an open pneumothorax is, under normal conditions, in proportion to the size of the opening in the chest, and he has worked out a formula which would indicate, when the vital capacity had been ascertained, the size of the opening in the chest that a given patient would stand.

A rough estimate of the vital capacity can be obtained by the observation of three factors:

1. Rate of respiration.
2. Amplitude.
3. Condition of the circulation as shown in the extremities.

It will be obvious that if the respirations are around thirty or forty a minute and the amplitude is as great as possible, and still there is cyanosis and coldness of the extremities, then the vital capacity and tidal air are dangerously near the same and that any further interference, such as even a small open pneumothorax, may be enough to push the patient over the brink.

Taking 4,800 c. c. as the normal vital capacity for a man, Graham found that an opening 10.4 square inches could be made in the chest, as long as the respiratory muscles could maintain a maximum effort without producing serious results.

This theory is borne out in practice by the fact that large openings have been made in the chest over short periods of time, either by intent, as at time of operation, or as the result of large shell fragment wounds. On the other hand, he found that a patient, who had an empyema and had a vital capacity of 1,600 c. c. and who should have stood an opening in the chest of 3.3 square inches, was made markedly dyspneic by an opening of 2.1 square inches. This would indicate that under pathological condition, rather less than the maximum opening can be made with safety.

TREATMENT

When fluid in the pleural cavity is suspected or assured by physical examination or by x ray, aspiration should be done under local anesthesia where indicated (usually in the seventh or eighth interspace in posterior axillary line) and the character ascer-

Fig. 4.—Case VII, E. P. The same patient two weeks later.

tained. If clear fluid is withdrawn as much of the fluid should be removed as possible without causing too much inconvenience to the patient, such as pain,

coughing, and dyspnea. Clear, strawcolored fluid in a patient running a temperature usually means a tuberculous condition. To make sure of this diagnosis some of the fluid should be injected into the peritoneal cavity of a guineapig. If cloudy or slightly cloudy fluid is withdrawn, a smear should be made and the fluid cultured to ascertain the exciting organism. This at most only means a delay of from twenty-four to forty-eight hours, and in the meanwhile the patient is relieved of the embarrassing presence of the fluid, and the lung is allowed to expand somewhat and further stabilize itself by adhesions. Where the infection is of streptococcal or staphylococcal origin one of two courses is open, i. e., repeated aspiration or drainage by the closed method. If the culture shows pure pneumococcus and frank pus is present, the latter procedure may be carried out or intercostal drainage or rib resection resorted to.

Bülau in 1890 described a closed method of draining the pleural cavity which seems to be the basis of the socalled Mozingo method of the present day. The former advocated the insertion of a rubber catheter through a cannula, which had been introduced into the pleural cavity through an intercostal space. The cannula is then removed and the catheter left in place. A connection is then made between the catheter and a rubber tube which is immersed in a bottle containing antiseptic fluid and so placed as to create syphon drainage. Mozingo omits this last step and aspirates through the catheter by using as asepto or Dakin bulb syringe. When all the fluid and air have been removed the bulb remains collapsed, showing that there is a vacuum in the pleural cavity. By this method it is possible to lift water eight feet in a six mm. tube, and by clamping the catheter a vacuum can be maintained for a number of hours.

A great number of devices have been used to produce a constant vacuum, but the one mentioned above has proved satisfactory in my hands and has the great advantage of being simple and easy of construction. With a little instruction a nurse can aspirate the fluid that has accumulated from one dressing to another (usually at three hour intervals), and on one occasion I allowed the patient to go to his home in the country with the tube in place and an intelligent member of the family carried out the treatment. The one hitch in the procedure seems to be that in a number of cases there is leakage of air around the tube beginning any time after the first three or four days, which prevents or limits the negative pressure within the pleural cavity. This is obviated in some instances by pressing a piece of rubber dam down and fitting it snugly about the catheter and glueing it to the chest wall with St. Claire glue. Seeing the need of a more efficient means of preventing leakage I had made a catheter encircled by a pneumatic jacket. When after a few days, the result of infection and retraction of the tissues along the tract, there is leakage of air, the original tube is withdrawn and the pneumatic jacket tube inserted. If there is any difficulty in inserting the latter, the distal end may be closed temporarily by tying the tip with oo plain catgut and a probe placed within the lumen. This will give added stability to the tube and allow gentle pressure to be made. The catgut will soon be absorbed, reestablishing the lumen and in the meanwhile aspiration can be carried out through the fenestrations that have been previously made on the side. Recently I have found in the literature a description and picture of almost identically the same device as used by Morelli of Bologna. He, however, does not limit their use to a small opening made by a trocar, but has three sizes, so that one or the other can be fitted in after intercostal incision or rib resection.

The most frequent objection to the closed method in treating empyema is that efficient drainage cannot be maintained. This has not so far been my experience. By the use of Dakin's solution for irrigation thick pus and inspissated particles of fibrin can be disintegrated and liquified so as to pass through the lumen of a No. 14 French catheter. If dense fibrinous adhesions about the lung do not loosen from being bathed for fifteen minutes every three hours in the usual 0.5 per cent. solution, Kanavel recommends the use of a two per cent. solution. If the patient fails to improve as a result of this treatment, it generally means that there is pus elsewhere that is not reached by the irrigation fluid, either a second pocket in the pleural cavity, a lung abscess endocarditis, or similar condiiton. In this case even a larger opening at the same site would not better the condition.

At the end of from ten days to two weeks the closed method may be discontinued. By this time the lung has generally expanded so that there is only a small area about the tube that has still to fill out and strong adhesions have formed which prevent the lung from contracting when a little air enters through the tube. All that is needed to convert the closed method into the open is to shorten the tube so that it extends only through the thoracic wall and allow about an inch to project on the outside. A safety pin is used to hold it in place. Mozingo advises injecting ten per cent. formaldehyde in glycerine into the remaining cavity after the tube is removed, but this has been known to become encysted and later give trouble. The criterion as to when to discontinue the closed method is the measurement of the size of the cavity. If the latter holds one or less Dakin syringe (capacity one ounce) full of air, it is quite safe to assume that the rest of the cavity will close, if a vent for any further secretion is provided by the open tube. Irrigation by Dakin's solution may be continued as before though not so often—usually twice daily will suffice.

Of the fifteen patients in this series all but one were treated by the closed method, either as a primary procedure or throughout their illness. The exception was made in this instance (Case IV) because of the preference for the intercostal method of the doctor for whom I operated, and because the operation was done out of town. It is interesting to note that in spite of the fact that a double tube of half inch lumen was used, the drainage at one time was insufficient. It is this result that brings forth the objection to the closed method by those who advocate what they are pleased to call adequate drainage and illustrate that the size and number of the tubes inserted into the empyema cavity do not necessarily insure drainage, but that a great deal depends upon irrigation.

In three other cases the closed method was used in the beginning and intercostal drainage resorted to later. In one of these (Case III) it was impossible to maintain a vamuum, due to the fact that air filtered in through openings made in the patient's back to drain multiple abscesses. About two weeks after the first operation Dr. Mitchell inserted two large tubes through an intercostal opening. X ray plates 1 and 2 (Case III) show very distinctly the difference between negative and positive pressure. In Fig. 1 the lung is expanded taking up nearly the entire cavity and in Fig. 2 it is contracted, leaving a tremendous dead space.

Case	Name	Age	Sex	Etiology	Organism	Method of Treatment	Complication	Results

14.	A. B.	18	M.	Pneumonia	No culture	Closed	None	Cured
15.	A. M.	3	F.	Pneumonia	Streptococcus	Closed and Intercostal drainage	None	Cured

In Case V the patient was operated upon four times. She began and ended with the closed method, but between these two operations which were done nearly a year apart, she had an open intercostal drainage and rib resection elsewhere. In Case XV the tube came out by mistake on about the tenth day, and when it was detected it was impossible to reinsert through the original opening. It was thought safer to locate the old tract through a skin incision than blindly by means of a trocar.

On two occasions the Dakin solution had to be discontinued as an irrigation because of hemorrhage or rise of temperature. It was found that after most of the fibrinous material had been cut away the Dakin solution acted on the tissues, causing irritation and bleeding. In one case there was also a marked rise in temperature which subsided immediately after normal salt solution was substituted. Leakage of air around the tube can usually be prevented by making the incision in the skin, where the trocar is to be inserted, a little smaller than the diameter of the trocar. By failing to observe this minor point we have been embarrassed by leakage around the tube which made it impossible to maintain a vacuum.

I want to emphasize the importance of leaving in the rubber tube after the closed method has been discontinued. Chronologically the routine is as follows: The closed method is kept up until the cavity holds less than two ounces of air, usually about the end of the second week, the tube is then shortened, left open and stabilized by a safety pin (Case XIV). Irrigations are now done once or twice in twenty-four hours and when no solution can be made to enter and no air is expelled when the patient coughs, the tube is removed entirely. The last stage may last another ten days or two weeks, but it is quite feasible during this period to handle the patient at his home. By using the combined closed and open method of drainage it is almost impossible for the external wound to heal leaving a circumscribed abscess.

1015 Sixteenth Street.

Unusually High Blood Sugar Content in a Case of Diabetes

ROBERT L. PITFIELD, M.D.,

Philadelphia

An emaciated man, of about forty-five years of age, was admitted to the Germantown Hospital in the afternoon. He was in a semicomatous state, talked incoherently and at random, and was difficult to arouse. His temperature was 95°, his feet and other extremities were cold. An odor of acetone was detected on his breath. Upon catheterization his urine was found to be loaded with sugar, acetone and diacetic acid. A blood sugar analysis showed that it contained an unprecedented amount of glucose, the reading of the Dubosque calorimeter done by artificial light and a ground glass mirror, was over 1700 milligrams to the 100 c.c. of blood, by the Folin Wu method.

Insulin was at once administered by vein. The first dose was forty units; forty-five minutes later fifty additional units were given by the same route. His condition being desperate, camphor, digitalis, atropine and caffeine were administered and artificial heat applied. In one hour after the first dose of

insulin, the blood sugar content had fallen to 842, due to the combined effect of the ninety units of insulin. However, he sank slowly and in another hour he was dead. Fifty units more of insulin had been given in the meantime.

When admitted, his wife, a woman of low intelligence, said that he had been in a semicoma since the midnight previous to admission. His attending physician thought that he was suffering from an intestinal obstruction as he complained of much pain in the upper half of the abdomen which was rigid. A simple enema afforded an easy evacuation of a clay colored stool. No autopsy was performed.

This case, incompletely reported, for the autopsy data were not secured, is presented because of the very high blood sugar content and because insulin in large doses given to a man all but moribund, with a low temperature, seemed to be futile to revive one so long in coma or semicoma. Previous to his acute illness the patient had not exhibited the common symptoms of diabetes. The blood sugar estimation was done by a competent pathologist who has had long experience in such work.

5211 Wayne Avenue, Germantown.

Modern Cataract Operations

A. GRAHAM BIDDLE, M.D.,
New York

The method of removal of a cataract from the eye of a patient who is over fifty years of age, has made decided advancement within the past few years. Many eye surgeons acknowledge the advantage of the newer technic but assert that having mastered the older method they are unwilling to make a change. In the opinion, however, of a greatly increasing number of eye surgeons, the most desirable method for the extraction of senile cataracts is one whereby the lens is removed within its capsule. The chief objection raised is the fear that the vitreous may be lost.

The technic and the apparatus used have been greatly improved, and a sufficiently large number of operations performed to prove that vitreous loss is not to be feared, and is most always the result of neglect of a part of the technic.

The lens within the eye, averaging ten millimetres in diameter, is enclosed within and supported by a very delicate and friable capsule. Around the periphery is a series of fine radiating elastic fibres, called the zonule of Zinn. This is attached to the ciliary body. Tension on these fibres by the contraction of the ciliary muscles produces an alteration in the shape of the lens, and thereby the act of accommodation. The zonule is composed of elastic fibres which are comparatively tough in youth, but as age advances, these become exceedingly soft and lose their tensile strength and are easily broken. Ordinarily the lens within the capsule is adherent to its inner surface, but after a cataract is formed, and it becomes harder and harder, the lens loses its adherence to the capsule. When this has taken place completely, and the lens is quite hard and separated from its capsule, the cataract is said to be mature, or "ripe" and ready for operation. This has nothing to do with the age of the individual. Many very old people have waited year after year for this ripening to take place, and are still waiting. It may occur in a few months or it may take several years, and meanwhile the patient is blind.

This hardening of the lens and separation of the capsule is essential for the proper performance of the older capsulotomy operation. By this method, an opening is made in the anterior surface of the capsule, and the hardened lens pops out into the anterior chamber, and is expressed by pressure on the limbus. Should the lens substance not be quite hard, it is necessary to manipulate the eye considerably to eliminate the broken down substance. Even at best it is impossible by this method to remove all of the lens fragments, or the capsule, which may be as opaque as the lens itself. This necessitates a further period of waiting and the patient's returning to the hospital for a second and even a third operation in an endeavor to rid the eye of the residue which remained after the first operation.

We all must admit that an operation which will remove the entire offending mass at one time and have a clear pathway for the rays of light to reach the retina is the one to be performed, providing the eye is uninjured.

The intracapsular operation was devised to do away with the long period of waiting for hardening of the lens to take place, and the violent irritation, and occasional loss of an eye, and the repeated operations necessary which occur as a result of leaving lens matter and capsule behind. Not infrequently this has been the direct cause of the loss not only of eyesight but also of the eye itself.

The majority of ophthalmologists are disinclined to remove the capsule and lens at one time for fear that the vitreous will be lost. The vitreous is a semifluid substance supported by a vast network of fine fibres and held in position by the delicate hyaloid membrane which covers the anterior surface. The lens rests in a small depression on its surface called the patellar fossa.

Loss of vitreous is occasioned by undue pressure on the eyeball. Pressure may be produced by the surgeon while operating, or by the patient by contracting the eye muscles during or following the operation. These may both be prevented. The fundamental idea of the intracapsular operation is simply the grasping of the capsule and lens, and by exerting gentle traction rupturing the brittle zonule fibres, without any pressure being exerted by the operator or the patient on the eyeball.

When the idea was first conceived, numerous instruments were devised for grasping the capsule and thus exerting traction. They were all failures, due to the friability of the capsule, which ruptured and thus transformed the operation into one similar to the linear extraction operation as is employed for soft cataracts.

Colonel Smith, in India, next devised the Smith-Indian operation, which is an effort to remove the lens and capsule without exerting traction on it, but by dislocating the lens with pressure and thus complete the operation at one time. It seems that the natives of India are fatalists, and they would give the surgeon one chance to operate, whether it be an iridectomy or cataract extraction. Afterwards if vision is not improved, they could not be prevailed upon to return again, as they felt confident that their vision never could be restored. Under such circumstances, the loss by the Smith operation was not greater than it would be by the older method if the surgeon tried to do everything at one sitting.

It has been found that few surgeons possess the ability to acquire the technic of the Smith-Indian operation, or to judge correctly the amount of pressure required to dislocate the lens. The dividing line between too much pressure and too little pressure lies at the point where a hernia of the vitreous might be produced. Therefore, this operation has not met with success in this country, and is rarely used.

Instruments have been devised to pass behind the lens, hugging its posterior surface, and thus scoop it out of its bed. These have been moderately successful but have a limited field.

It remained for Dr. Barraquer, of Barcelona, Spain, to devise a method of grasping the capsule, and hold it firmly, without rupturing. This he did by negative air pressure; in other words, by the production of a gradually increasing vacuum, the anterior lens surface would mould into a vacuum suction tip, and there be held securely by a steady even pressure, while the operator exerted traction. This ruptured the zonule fibres, and the lens and capsule, which is the cataract, could then be removed.

Dr. Barraquer came to America to demonstrate his method, and operated a number of times successfully. In a few cases it was found after the bandage had been removed, that there was a loss of vitreous. This has been the cause of some men discrediting the Barraquer method. It really was not due to a fault in the principle of this operation, but to the fact that the patient squeezed his eyelids, after they were bandaged, and is a part of the procedure which has since been corrected by our surgeons by deep injections of novocaine, and the performance of a canthotomy as part of the technic.

I have spent a considerable amount of time with the Doctors Green of San Francisco acquiring the method as practised by them. They have been more than a year with Colonel Smith in India, and a long period of time with Dr. Barraquer in Spain, and have ingeniously combined the two methods, using a slight amount of traction, together with a slight amount of pressure, and thus have made the intracapsular operation a success. They have also greatly improved the instruments used, and the operative technic, so that the percentage of loss has been reduced to a minimum and probably operate in as many cases of cataract as any one in America.

Now it is no longer necessary for a patient to sit around year after year half blind waiting for ripening to take place as is commonly believed, but the cataract can be removed as soon as the person is unable to see, as immature cataracts present no barrier to an operator who has acquired the technic of this suction method.

Of course all kinds of cataracts cannot be removed by the intracapsular method. Cases of congenital cataract, or of a dislocated cataract lens, Morgagnian cataracts, or traumatic cataracts in patients under sixty years of age are decidedly not suitable cases.

Not until the patient has passed middle life, is the zonule sufficiently friable to be ruptured by traction, without damage to the ciliary body. Morgagnian cataracts, where the lens matter has become liquefied, and the nucleus has settled to the lower portion of its capsule cannot be removed by this method. The contraindications of the intracapsular method are definite and rather infrequently encountered, and the number will be diminished as our technic improves.

The oil pump devised by Dr. Barraquer could not be depended upon to deliver just the right amount of vacuum at all times. The oil might become heavy on account of changes of temperature or a variance in the viscosity of the oil itself. Consequently the suction was not sufficient to hold the lens. Or the pump might exert too great an amount of negative pressure and thus rupture the capsule. Dr. Barraquer lays great stress on the effect of the constantly recurring strokes of the pump as an aid to the rupturing of the zonule. As a matter of fact, until the strokes have ceased, as they do as soon as the suction tip grasps the capsule, there is no pull at all on the zonule. In other words, when the suction has become of sufficient strength to take hold, the perceptible vibrations have ceased.

The oil pump has been replaced by one which uses mercury instead of oil. A great deal of time and effort have been spent in devising a pump which would produce a gradually increasing negative pressure, until the vacuum equalled twenty-nine inches of mercury, and hold this pressure constant, no more and no less, under all conditions.

In the Barraquer method, the valve controlling the suction is placed in the suction tip. This was found to be rather clumsy, and necessitated a shifting of the fingers which counted against a perfect operation. The shape of the tip has been changed, and the valve removed from it. In its place a foot controlled valve is used, leaving the suction tip unencumbered.

The model of the first suction tip, or vacuum forceps as it might be called, was a silver lead pencil, to which a moulded tip was added. Its sole purpose is to grasp the capsule without tearing, and hold it firmly. There is absolutely no sucking up of the lens substance into the tip and tube as one might suppose. A portion of the anterior capsule simply moulds into the tip in a gradual manner, conforming to the interior of the suction tip, and is there held securely and intact.

The lids are held by a specially devised retractor, which is applied only to the upper lid. The lower lid

is held by a finger of the same hand which holds the retractor, and the assistant is thus enabled to remove the retractor instantly, if necessary.

The deep injection is made by passing the needle through the skin and along the floor of the orbital cavity, and three c. c. of a two per cent. solution of novocaine with suprarenin (especially prepared), injected beneath and behind the eyeball.

An element of success in this operation consists in eliminating all excitement and nervousness on the part of the patient. This is obtained by a very careful preparation, and especially keeping the patient well under the influence of sedatives.

It is perhaps unnecessary to describe all the intricate details of the operation itself, as it should be performed only by a surgeon who is especially prepared and has been provided with all the necessary apparatus. However, when performed by those surgeons who have made a special study of this combined method, and who follow the prescribed technic to its minutest details, the results are equally as successful, and often far surpass all other methods, and I fully believe that the operation for the removal of cataracts by suction will be the operation of choice in the future.

The Advantages of the Stylet Used with the Rehfuss Tube

Suggested Modifications

M. GOLOB, M.D.,
New York

In the course of my experience with the many duodenal tubes on the market, I have come to the conclusion that the use of a stylet in the process of getting the tube into the stomach results both in saving time and in reducing the patient's discomfort to a minimum. I have found this to be true, irrespective of what particular tube may be favored by the practitioner, but for my own part, I have secured my best results when using the stylet in conjunction with the Rehfuss tube. The latter is, on the whole, admirably adapted to its functions because of its well designed capsule, which permits the aspiration of a composite specimen through its spacious fenestrations and also enters the duodenum the more readily because of its oliveshaped tip.

ADVANTAGES OF STYLET

The advantages gained by the use of a stylet arise from the simplification of the process of getting the tube *in situ*. Left to his own initiative as, perforce, he must be when no stylet is used, the average patient undertakes this distasteful task with great reluctance and succeeds only after repeated effort. The flexibility of the tube limits the swallowing to about a centimetre of tube with each deglutition, thereby prolonging the annoying procedure. Indeed I have found that in many instances hypersensitive patients actually suffer considerable nervous distress from their efforts and some even dread the prospect of a repetition.

With the use of a suitable stylet, the patient is relatively passive. The stylet is adjusted into the tube, which is then inserted into the throat of the patient and, with firm pressure of thumb and forefinger upon the tubular walls, the tube is pushed gently downward into the stomach. The stylet is then withdrawn. The time the whole process ordinarily consumes is but a matter of seconds.

The stylet I have found most suitable is a modification of that used with the Jutte tube. Its length is about eighty-five cm., that is, just enough to reach into, but not beyond, the shank of the capsule. It is finished in a knob at its distal end to prevent piercing the tube, and in a loop at the proximal end for the convenient insertion of the finger to facilitate withdrawal of the stylet and also to prevent extrusion of the distal end through the fenestrations of the capsule.

PRINCIPLES OF OLD DUODENAL TUBES

Most of the duodenal tubes on the market make a virtue of the intentional weighting of their capsules, on the theory that they thereby gravitate more rapidly to the duodenum. This is undoubtedly true respecting the course from the pharynx to the stomach; but from there to the duodenum, I believe the extra weight is of no advantage whatever, and may prove an actual obstacle in case of weak peristalsis.

For example, in a stomach which is of the subtonic or atonic type with a sluggish peristalsis, a weighty sinker may prove too much to be carried by a weak wave along the lesser curvature, in which case, most naturally, it would seek the lower pole and depend there. Indeed, the Jutte tube, which bears the lightest and smallest capsule of all, effects its entrance into the duodenum more rapidly than the Rehfuss or any other tube; but, unfortunately, it is deficient in its effectiveness in aspiration. Of course, for passage through the esophagus, the stylet does away with the need for a weighted capsule.

A slight modification of the capsule borne by the Rehfuss tube, by which it would be adapted more thoroughly to the use of a stylet, would make possible a somewhat more mechanical routine in getting the tube into position. The inner diameter of the shank may be widened somewhat to afford passage of the stylet through it, the knob of which should be of sufficient diameter to prevent extrusion through the fenestrations. The stylet would be sufficiently lengthened to permit it to rest against the inner surface of the capsule. The tube could thereby be brought into the stomach by the simple process of pushing it down with the stylet.

Practical Therapeutics

ANILINE DYES IN THE TREATMENT OF INFECTIONS

F. McKelvey Bell, M.D.
New York

For the past three years I have been using aniline dyes locally, intravenously, and by a special intracolonic method (enterocylsis). To date, while much has been written regarding the use of aniline dyes, little has been said about reactions, complications, and contraindications. Hence it is the purpose of this paper to go into detail regarding these important and hitherto unconsidered questions.

From the excellent reports on the use of mercurochrome and gentian violet in septicemias by Hugh H. Young (1), Young and Hill (2), and on gentian violet by Smith and Casparis (3), and similar experiences of mine with neutral acriflavine, it seems as yet of small importance, at least with gram positive organisms, which of these dyes is used—the action of each being approximately the same. In time we shall probably find reasons for differentiation.

Churchman (4) by his laboratory experiments proved (as has also been shown clinically) that gentian violet and neutral acriflavine are bacteriostatic. Churchman (5) also showed that gram negative bacteria continue to grow on agar after exposure to gentian violet, gram positive bacteria die under similar exposure (normal selective bacteriostasis). Acid fuchsin was found to have the opposite effect in each case (reverse selective bacteriostasis). Neutral acriflavine in the laboratory was found to have the same power as acid fuchsin, but clinically, when given intravenously, the action of neutral acriflavine resembles also that of gentian violet. When used locally, however, the laboratory and clinical results coincide. A mixture of gentian violet and neutral acriflavine (acriviolet) possesses bacteriostatic powers against both gram negative and gram positive bacteria, the mixture being stronger in bacteriostatic power than either dye used separately. It does not follow that either dye individually cannot kill certain strains of both varieties of organisms. Clinically (if not actually) the staphylococcus, streptococcus, bacillus pertussis, pneumococcus and other bacteria are killed or inhibited by the one dye. The gram negative gonococcus is always resistant and some strains are evidently totally immune to neutral acriflavine.

Churchman (6) pointed out that a dye heated to 35° C. may have no bacteriostatic properties but this heated to 50° C. becomes an efficient bactericide. Clinical advantage may be taken of this phenomenon (the reason for which is not fully understood) by seeing that our solution for intravenous use is heated slightly above the normal temperature of the blood, i. e., from 105-108° F.

As most of the experimental work done by me is confined to the use of neutral acriflavine, conclusions are based on treatment with this dye. In a number of cases a new dye, acriviolet (Churchman), was used.

The conclusions arrived at are based upon a series of 122 cases (ninety-two medical and thirty surgical) although the medical cases only will be discussed in this paper.

In each adult patient, unless otherwise stated, the dose of neutral acriflavine was fifty c.c. of a half per cent. solution given intravenously. Doses for children were smaller, in proportion to age and size, the strength of the solution being 0.5 per cent. and the treatment by the intracolonic method.

It would be impossible on account of lack of space to give complete histories of each of the cases treated, but details will be given of unusual and almost miraculous cures in such conditions as Ludwig's angina, pertussis, mumps, bronchopneumonia and others.

Treatment of acute conditions to be reported showed satisfactory results. Chronic conditions were not so tractable.

1. Acute bronchitis (eight cases), two of which were postoperative, violent and distressing in character, responded to one or two injections of neutral acriflavine. Where a second dose was needed it was given forty-eight hours after the first. Coughing and expectoration ceased abruptly in six cases after one injection and within twenty-four hours. In the other two it took seventy-two hours. No other medication was used or needed.

2. Lobar pneumonia (four cases—adults). One was postoperative, in which pneumococcus (type 4) was demonstrated in the sputum. All cases had definite symptoms; cough, rusty sputum, respirations 36-40, temperature 102-105° F. An artificial crisis was produced in each case in twenty-four hours with the usual injection. But early diagnosis and early treatment seem essential to get these results.

3. Bronchopneumonia. a. Five cases in children two to five and a half years of age. Two required a second dose twenty-four hours after the first injection (by enteroclysis). Temperature dropped in eighteen hours in three cases from 103-105.2° F. to normal. In two cases, after twenty-four hours it again rose to 100-101° F. The second injection reduced it to normal and cleared up the disease. An interesting feature of these cases was that the respirations of from 40-50 fell synchronously with the temperature to normal.

b. Bronchopneumonia in a man sixty-eight years of age who was debilitated as a result of diabetes, chronic nephritis, and angina pectoris. The first injection of neutral acriflavine made a marked improvement. Temperature dropped from 102.3° F. to normal but the second dose had no effect. He died on the fifth day of the disease.

4. Pertussis (one case, child three years of age). On the tenth day of the disease the child whooped and coughed incessantly, vomited all food and in twelve hours was delirious, pulse 150 and thready. Twenty c.c. of 0.5 per cent. neutral acriflavine solution were given by enteroclysis. Within twelve hours there was only an occasional slight whoop, not particularly distressing. After twenty-four hours slight whooping occurred only three to four times a day.

At the end of forty-eight hours a second dose was given, which terminated the treatment and practically eliminated the disease. Within one week after the first treatment and on the seventeenth day of the disease the child was quite well and rarely coughed. Five doses of pertussis vaccine had been given to this child two weeks before the onset but had no apparent effect either as a prophylactic or cure. A younger sister treated a few weeks previously with pertussis vaccine (five doses) but no neutral acriflavine, ran the usual severe course.

5. Erysipelas. a. Six cases, one failure. In three cases of facial erysipelas two injections forty-eight hours apart caused cure within seventy-two hours of the first treatment. In the case of a child four years of age where the disease had steadily progressed for two weeks in spite of all other methods of treatment and had spread over half the body; as a last resort twenty c.c. of neutral acriflavine half per cent. were given; but it required three injections to cure. The first two were given twenty-four hours apart, the last one forty-eight hours later.

b. Erysipelas and deep cellulitis of the arm in a barber who had cut his left hand with a razor. This patient was not seen until the eighth day of the disease. He died of general (streptococcic) septicemia on the fifteenth day of the disease.

6. Ludwig's angina (one case), left side of neck involved. Incision showed a gangrenous appearing cellulitis with a small pocket containing about four c.c. of pus. The disease spread rapidly and within twenty-four hours the left eye was closed, the ear, and the entire left side of the neck as far as the occiput were deeply infiltrated. Neutral acriflavine was then given. Within twelve hours the spread of the disease had ceased. In seventy-two hours the patient was well. He left the hospital on the fifth day with only slight drainage from wound.

7. Carbuncles (three cases). Same result as in Ludwig's angina, but two injections twenty-four hours apart were required in each case.

8. Orchitis following mumps (one case), temperature of 103-104° F. daily for five days. Both testicles swollen to size of a large orange. Great restlessness and sleeplessness but no pain. Fifty c.c. of neutral acriflavine were given on the sixth day of the fever. After twenty-four hours temperature still 104° F., no improvement in inflammatory conditions but twelve hours later sudden drop to normal. No further rise of temperature. Patient left the hospital cured on the third day following the injection.

9. Mumps (three cases). One treatment cured each of them. Stiffness and swelling commenced receding within twenty hours after treatment. Glands apparently normal in forty-eight hours, instead of seven to ten days as in the usual course.

10. Acute arthritis (two cases). a. Both wrists, left elbow and both knees involved. Had had an attack one year previously. Temperature 100-102° F. for three days. Chronic endocarditis was a complication. Two treatments given forty-eight hours apart. Temperature normal after twelve hours, pain gone in twenty-four hours. Patient left hospital three days later. A slight neuralgia in upper arm persisted for two weeks, but joints were then and are still normal. Mark and Olesker (*7*) showed the remarkable value of massive doses of neutral acriflavine in acute arthritis and endocarditis.

b. The second case was a severe recurrent arthritis of the right knee joint (cause unknown). It required two injections to cure. Each injection caused severe pain in joint lasting six to eight hours. Temperature ranged from 101-102° F. and fell only after second injection. Pain, fever, and swelling disappeared forty-eight hours after the second injection. Total time in bed was six days. Was able to work on seventh day from beginning of attack.

11. Gonorrhea in women (twenty-seven cases). These for the most part were old institutional cases of endocervicitis and vulvitis. From a résumé of this series of cases it is fairly evident that while neutral acriflavine (local and intravenous) is a valuable addition to our armamentarium it is not a specific in either acute or chronic gonorrhea in women. Its chief advantage lies in the lessening of discharge and irritation in the acute stages or in chronic mucopurulent (mixed infection) vaginitis. Its use must be followed up with other forms of treatment.

Why is it that in certain infections, or at certain stages of an infection, dyes give only a transitory effect, in so far as improvement is concerned, while in other similar cases an immediate response and cure takes place? There are probably two good reasons for this. a. In cases where areas are densely infiltrated and the local circulation is consequently impaired the dye does not penetrate all the tissues, e.g., deep cellulitis or advanced lobar or bronchopneumonias. The temperature drops as the bacteria which can be reached are overcome but the patient soon reinfects himself from the local area. b. In other cases where there is no dense infiltration or interference with the circulation it must be that certain strains of bacteria are more resistant than others or are of a type which cannot be killed by the particular dye used. Free drainage of pus is essential.

DOSE

No definite rules regarding doses of neutral acriflavine have yet been laid down. Mark and Olesker (*7*) believed that no harm would result from massive doses of ten mg. per kilo of body weight. This has been confirmed by the writer, but such large doses are rarely necessary.

1. Women are much more inclined to nausea and vomiting after the use of large doses of dye than men (fifty c.c. or over of one per cent. solution).

2. Old people do not stand as large a dose as young healthy adults. The initial dose for them should be thirty to thirty-five c.c. of half per cent. solution.

3. Children bear the first injections well, the dose being estimated by the old formula, i.e., the child's age over the child's age plus twelve of the adult dose.

4. Injections cannot be repeated more than four or five times at intervals of one week or less apart without causing annoying and sometimes alarming symptoms such as precordial pain, nausea, vomiting, and gastritis.

5. In chronic conditions half the maximum dose is quite as useful as the full dose.

6. In acute and violent infections in adults the maximum dose (fifty c.c. of a one per cent. solution) should be given at once and if necessary followed in forty-eight hours by a similar amount.

7. In acute infections unless the first two doses give a definite result such as reduction of temperature, relief of pain, etc., subsequent doses seem to be useless and may be harmful.

8. The usual dose used by me in acute conditions for healthy male adults of 150 lbs. weight or over is fifty c.c. of one half per cent. solution and in chronic conditions half of this amount. If the dye is likely to be effective in any given case this dose will be sufficient.

REACTIONS AND COMPLICATIONS

1. Within a few minutes of the injection of forty c.c. or more of neutral acriflavine in most cases the skin assumes a yellowish hue similar to that seen in jaundice. This does not entirely disappear for forty-eight hours. The dye appears in a few hours in the urine, tears, sweat and the vaginal secretions and will be excreted for approximately forty-eight hours.

2. Doses of more than thirty-five to forty c.c. of one per cent. solution to the average adult woman in about twenty-five per cent. of the cases will cause vomiting at least once and in some cases this vomiting recurs several times within the twenty-four hours. Vomiting sometimes occurs within five minutes of the injection. In none of our cases were men affected in this way even where fifty c. c. of one per cent. solution or more were used.

3. Old people (sixty-five to seventy-five years of age) after a second injection, if the dose is too large, complain for several days of weakness, lassitude and a feeling of general depression and may refuse further treatment on this account.

4. After the fourth or fifth injection, one week apart, some patients develop an attack of what appears to be gastritis, with loss of appetite, burning sensation in the epigastrium and occasional nausea. It may last a week or ten days but will clear up automatically without treatment. This reaction has occurred three times in the series.

I must leave it to the physiologists to explain several of the phenomena noted above. Why women are more subject to nausea or gastritis than men is not quite clear. It may be mechanical or chemical irritation of the gastric mucosa during excretion. It can hardly be explained upon a theory of nervousness as the reactions occur in women who are perfectly normal and hours after the injection is given.

5. One patient (female with chronic gonorrhea) presented albuminuria after the first injection of thirty-five c. c. of one per cent. solution and another who had slight albuminuria developed an acute nephritis with casts. Both of these cases cleared up shortly when no further injections were used. This suggests that uranalysis should be made before and after each injection.

6. In two patients (fifty-four and seventy years of age respectively) there developed severe pains in the chest (without fever). The pains were suggestive of intercostal neuralgia and lasted to some extent for ten to fourteen days.

CONTRAINDICATIONS

1. As far as I have seen the only two contraindications of importance which we can anticipate are old age and albuminuria. The former demands caution and smaller doses. Patients who have some idiosyncrasy against the dye and have had syncope or cyanosis following its use should not be given a subsequent dose.

2. Emphasis must be laid on the danger of using more than four or five injections at weekly intervals in one patient until further investigation is made of the phenomena reported, precordial pain, nausea, gastritis, etc. It is important that the solution be carefully filtered and be freshly prepared before use.

3. If the needle passes through the vein and any of the solution becomes extravasated into the tissues an immediate burning pain is felt at the site of the injection. A chemical cellulitis similar to that caused by salvarsan follows.

Diabetes is not a contraindication. Three cases of this disease where the dye was used showed no ill effects.

INTRACOLONIC USE OF NEUTRAL ACRIFLAVINE FOR CHILDREN OR ADULTS

Finding it difficult to enter the vein in small, nervous children and sometimes in plump women, the following technic for intracolonic injections was developed. Enteroclysis with neutral acriflavine seems quite as efficient as the intravenous method, although a little more troublesome to use. Acriviolet causes irritation of the colon and is usually expelled too soon to take effect.

The colon is thoroughly irrigated with one half to one gallon of one per cent. sodium bicarbonate solution. The child is allowed to rest for one hour or until the colon shows no further tendency to evacuate. According to age and size, twenty c. c. of 0.5 per cent. solution of neutral acriflavine or a proportionate dose is given to children through a catheter high into the colon. The foot of the bed is elevated twelve inches and the child's hips are further raised upon the pillow which is removed from under the head. The patient must remain in bed for three hours either on the back or right side and no food is to be given during this time. If it can be prevented it is important that the bowels should not move again the same day. The same technic, but of course a full dose, is used for adults whose veins are unsuitable for intravenous treatment.

In conclusion, it is my conviction from a review of the cases treated that a large number of acute infectious diseases (excluding gonorrhea) can be easily and rapidly cured by the use of aniline dyes. It seems necessary that early diagnosis be made and early treatment instituted in order to get uniformly good results. It remains for the patient investigator and clinician to discover definitely which diseases are amenable to a particular dye. I believe that in time aniline dyes will replace many drugs, vaccines, and sera at present in use and will open a new era in the therapeutics of disease.

THERAPY OF THE NONSPECIFIC PROTEIN REACTION*

Observations Based on the Intramuscular Injection of Venom Protein (Crotalin) Solution in Six Hundred Cases

Ralph H. Spangler, A.M., M.D.,

Philadelphia

(*Continued from page* 389)

LOCAL REACTION AND SYSTEMIC EFFECT

The degree of local reaction obtained from venom protein injection varies with the size of the dose and individual susceptibility. In most cases the patient complains of a slight burning or stinging sensation at the site of the injection which frequently radiates up and down the forearm for a few minutes. No further effect is noted for from two to six hours when more or less swelling, with sometimes a slight erythema, appears. The amount of local reaction produced varies in different subjects and a variance in susceptibility from time to time is often shown in the same individual. In the average patient there is but little cellulitis at the site of injection and this usually reaches its maximum in from twenty-four to thirty-six hours. The injected area will usually return to normal in two or three days.

As a rule venom protein injections, in doses ranging from one four hundredth to one fiftieth grain, produce no chill, fever, sweating or other systemic disturbance. Occasionally there will be a slight elevation of temperature for a few hours, but in most patients the normal temperature range is not disturbed. In many patients a feeling of euphoria is expressed a few hours after receiving an injection.

EFFECT OF VENOM PROTEIN ON THE BLOOD METHOD OF REGULATING DOSE AND FREQUENCY OF INJECTION

It has always been my practice to count the red and the white cells, to estimate the hemoglobin and to make a differential leucocyte count on each patient before any venom protein was used. More than three thousand white and red counts have also been made at the height of the local reaction and after it has subsided in this series of cases. Differential leucocyte counts were made twenty-four, forty-eight or seventy-two hours following the injections and the proportional relation of the white cells noted and compared.

An increase in the number of erythrocytes in twelve, fourteen or thirty-six hours following an intramuscular injection of venom protein has been a uniform finding. By comparing the total leucocyte count before and after injection it has been the rule to note a slight leucopenia within the first six or twelve hours, and by twenty-four or thirty-six hours to find the total number of white cells about what they were before the injection. I have never seen an increase to twelve or fifteen thousand or what could be called a leucocytosis from crotalin injections.

The following table illustrates the effect of venom protein injections on the red and the white blood count in a case of a thirty year old male epileptic:

TABLE I

EFFECT OF VENOM PROTEIN INJECTIONS ON RED AND WHITE BLOOD COUNTS

Day of Month and Hour	*Relation of Blood Count to Time of Infection or Convulsion*	*Leucocytes*	*Erythrocytes*

In 1913 I called attention to the value of a routine study of the differential leucocyte count (6) as a guide to determining the strength of dose and frequency of administration. The injection of venom protein in over six hundred cases, in which the differential blood counts have been recorded and compared, has led me to make it a routine rule to use the percentage of eosinophiles produced following an injection as a guide to the strength dose of venom protein as well as to the frequency of administration.

As pointed out above (Table I) venom protein injections are not followed by a general leucocytosis, but they do alter the proportional relation of the cells in the differential count. In large enough doses to produce mild anaphylaxis, I have seen an increase of eosinophile cells to as high as twenty-five and even forty per cent. with a corresponding reduction in the relative number of polymorphonuclears.

Clinical experience seems to indicate that with crotalin injections in doses large enough to cause a biological reaction following which not more than an eight to ten per cent. of eosinophilia appears in the differential leucocyte count, we have an agent which produces a state of cell stimulation and altered permeability of cell walls corresponding to that stage in the mechanism of the nonspecific reaction which is of therapeutic value. This stage might be termed a preanaphylactic state.

As a rule the highest percentage of eosinophiles, following the range of doses (one four hundredth to one fiftieth grain) which I have used, occurs by the

*Read before the Philadelphia County Medical Society, April 9, 1924.

second or third day. In from five to seven days after an injection, the eosinophile cells as a rule will again have dropped to four per cent. or under and the patient may be given another injection. It has been my practice not to repeat an injection if the percentage of eosinophile cells by the fifth day has not dropped to at least four per cent. Moreover, it has not seemed wise to increase the strength of dose as long as any given strength is producing an eight to ten per cent. eosinophilia on the second or third day after injection.

TABLE II

EFFECT OF VENOM PROTEIN INJECTIONS ON THE PROPORTIONAL RELATION OF THE LEUCOCYTES IN THE DIFFERENTIAL COUNT.

Day of Month	*Relation of Count to Time of Injection and Convulsion*	*Poly.*	*S.L.*	*L.L.*	*Eosin.*	*Baso.*	*Trans.*
2nd	Before injection.	67	20	4	3	—	6
4th	42 hours after injection	58	27	2	8	1	4
9th	Before injection and 5 hours after convulsion	88	9	1	—	—	2
11th	45 hours after injection	61	18	3	8	1	9
16th	Before injection.	70	14	4	1	1	10
18th	48 hours after injection	58	23	5	6	—	8
23d	Before injection.	65	24	2	2	—	7
25th	42 hours after injection	55	22	5	9	1	8
29th	Before injection.	71	20	1	3	—	5
31st	45 hours after injection	57	29	2	6	—	6

To sum up my experience, I have found that when venom protein injections are given intramuscularly and are regulated by the percentage of eosinophiles in the differential leucocyte counts, they produce little local reaction and discomfort. Moreover, there is no shock or vasomotor paralysis and practically no disturbing systemic reaction. Chill, fever, nausea and vomiting or depressing symptoms have been absent, and patients receiving crotalin injections on an average of once a week can attend to their routine occupations without the slightest inconvenience.

OBSERVATIONS ON PRACTICAL THERAPEUTIC EFFECTS

We do not know the fundamental processes underlying the symptom complex of disturbed metabolism we term epilepsy, but in an experience with the treatment of over six hundred cases I have witnessed some striking therapeutic results following the nonspecific reaction of venom protein. In earlier papers I have submitted detailed case reports and will add none at this time. Venom protein has not relieved or even improved the convulsive symptoms in all of my cases. However, when one considers the depressing effect of the bromides and has witnessed the mental deterioration and maniacal outbursts which occasionally follow the excessive use or sudden withdrawal of luminal, it is a great satisfaction to note the improved metabolism produced by the nonspecific effect of venom protein.

Independent of the convulsive symptoms which have been relieved or greatly modified in many of my cases, the effect of the venom protein injections on the general metabolism and health of the patient has been uniformly beneficial. It is the rule for the patients to gain in weight. The stimulation of the red bone marrow following crotalin injections increases the number of the erythrocytes. The hemoglobin percentage rises and the patient experiences a feeling of well being which is very evident.

The general resisting power of patients who receive venom protein injections is increased and intercurrent illness is infrequent. Injuries and cuts as a rule heal promptly without infection. Susceptibility to infection and contagious diseases is lessened. I have seen epileptic children who were receiving venom protein injections exposed to scarlet fever, measles, chickenpox and grippe and not contract the disease. Following the influenza epidemic of 1918, I reported an observation made on forty-four patients who had been receiving venom protein injections for three months or longer, thirty of them were directly exposed in the same house with one or more persons suffering with influenza and yet only three of the forty-four patients presented modified symptoms of the infection. In two other patients to whom one injection of venom protein had been administered severe cases of influenzal pneumonia developed.

Finally, I wish to call attention to the adjuvant effect of venom protein injections when administered in conjunction with other drugs and the glands of internal secretion. Its adjuvant effect, when used with luminal, is illustrated in the following case:

Case I.—Eight months ago an eighteen year old high school girl was referred to me with the following history: She had had spasms in infancy and at the fourteenth year fainting spells with almost daily seizures of petit mal began. Six months later menstruation was established but was always irregular at six, eight or ten week intervals. About this time convulsive attacks began but seemed to bear no relation to menstruation. Bromides had been given without results. For six months before I saw the girl she had been on luminal which had been increased to six grains daily. At this time she complained of drowsiness, constant vertigo and loss of ability to concentrate so that school work had to be discontinued. In spite of the large doses of luminal she had four grand mal and daily petit mal seizures during the two weeks before I first saw her.

Venom protein injections were started at weekly intervals and the luminal was reduced to one and a half grains daily for a month and then to three quarters of a grain. This latter daily dose of luminal has been continued with a weekly injection of one one hundredth grain of venom protein for the past seven months. During the eight months the patient has been getting the venom protein injections and the small dose of luminal, one grand mal attack has occurred and she has had two petit mal seizures. The young lady is back at high school finishing her senior year. She is mentally alert, has lost much of her apprehension. Six menstrual periods have occurred in the course of eight months.

Space will not permit me to detail case reports showing the adjuvant effect of venom protein in conjunction with the use of other drugs. I will only mention that in cases of migraine, periodical neuralgia and arthritis, I have seen the value of iodides, acetanilide, and the salicylates greatly enhanced by the adjuvant effect of venom protein.

Historical Medicine

Historical Evolution of the Doctrine of Crises in Disease*

CHARLES GREEN CUMSTON, M.D.,

Geneva, Switzerland

Montaigne has said: *"Les arts et les sciences ne se jettent pas au moule, ains se forment et figurent peu à peu en les maniant et polissant à pleusieurs fois, comme les our façonnent leurs petits en les lechant à loisir."* How true this is of medicine. In all ages physicians have been struck by certain sudden intense phenomena, following which an apparently serious acute disease fades away and disappears. Certainly it is most fascinating to observe the sudden cessation of a pneumonia occurring on a practically fixed day, with almost constant phenomena.

The actual existence of these facts has never been denied, but their nature has given vent to numerous contentions and for this reason I have considered it a matter of historical interest to follow through the past the discussions that have arisen in respect to this subject. In point of fact, the doctrine of crises in disease has invariably faithfully reflected the image of the opinions of all past general pathologists, as well as medical philosophers. This doctrine offers us the opportunity of realizing the general tendencies of the opponent schools and reveals the fact that in all ages both physicians and thinkers have been divided into two chief sects. Those possessed of a synthetic mind have attempted to classify facts, then to interpret their meaning; others of analytical minds have declared that it is enough to record facts whose explanation is only to be sought for in tangible phenomena.

This divergence of opinion is clearly accentuated in the early medical writings that have come down to us, and Hippocrates, and with him the School of Cos, leads the partisans of synthesis. The history of crises in disease has been thoroughly dealt with by the writers of the early part of the last century and they affirm that on this point the opinions of Hippocrates are rather variable. But I cannot subscribe to this opinion, because, quite to the contrary, one may construct a rather fixed doctrine if, with Littré and Daremberg, care be taken only to select from the hippocratic collection those writings directly emanating from the School of Cos and to leave aside those which have been altered by the Cnidian Schol.

Clearly, Hippocrates in his book on *Airs, Waters, and Places,* does not scorn details, because when treating of the etiology of disease, he insists upon external influences—cosmic and others—but still more, he asks by what organic means these palpable causes—be they exact or erroneous—act and how they give rise to disease. Thus following the current of preceding doctrines, Hippocrates attributes disease to a defect of the organic humours. Health is the result of crasis of the humours, that is to say, their mixture in proper proportions. Now, if the crasis is disturbed by a qualititative or quantitative change of the fundamental fluids of the economy, the result will be organic suffering. During a pathological state the humours—tenous or crude—circulate throughout the body and then undergo a transformation in the form of a kind of thickening and mollification or coction, a process similar to what takes place when certain substances are cooked. All this is due to the action of vital forces, to the happy interference of *vis medicatrix naturæ,* which has become engaged in the struggle against the morbific principle. Then after coction of the peccant humour, the *vis medicatrix* tends to expel it.

During the struggle the organism will be—according to circumstances—either victor or vanquished, and the crisis is the judgment handed down in either case. Thus the crisis will be favorable or bad, perfect or imperfect. The complete expulsion of the deleterious agent by way of the natural outlets constitutes a favorable crisis. But nature likewise may be powerless completely to eliminate the cause of the affection. Or else the noxious humour having undergone coction may enter into some particular organ or organs instead of being directly conducted to the emunctories. In these circumstances a crisis from deposit results which will have a happy outcome if the organ involved is of small importance, but when the viscus is indispensable to life, the result will be an unfortunate one.

Briefly put, a crisis is the end of morbid evolution. Frequently it takes place at determined times; there are days of predilection called critical days and these may be calculated ahead of time by a close examination of phenomena occuring on certain preceding days, called indicative days. And Hippocrates, in all probability obeying the Pythagorean doctrine of numbers, emitted the law of septinaries and semiseptinaries. But he maintains a prudent reserve in respect to this, and teaches that a crisis may take place the evening before, or on the day following the day on which it should ensue. Consequently, the physician above all things should watch the evolution that nature tends to develop, although he is obliged to direct the course of events, as is clearly stated in the work on *Humours, I* and *IV*. The naturist did not meditate on death, as Asclepiades later on maintained; he meditated on the crises, above all things studying every phenomenon common to disease, its progression and natural evolution, and with this end in view, he took into consideration the patient's general health, searched his antecedent history, observed the present, and scrutinized the future. Briefly put, for the Cosan School, medical science in its entirety converged towards prognosis.

Such are the ideas Hippocrates especially developed in this book: *The Prognosis.* It is prin-

*A lecture delivered before the Geneva Medical Society, October 25, 1923.

cipally in this work that the chief of the Cosan School considers in detail the organism and the disease, and concludes by saying: "One should never ask the name of a malady which is not to be found in this treatise, because all those that are recovered from within the limits of time given are all to be recognized by the same signs."

However, already at this epoch an inverse tendency is to be found in the Cnidian books of the hippocratic collection. Morbid varieties have been multiplied, and subdivided, and hence often happy descriptions were given, but in which a general directing idea was wanting. Thus the doctrine of crises lost both simplicity and unity; a fact that has caused many of Hippocrates's commentators to say that the physician of Cos often varied in what should be understood as a crisis.

The conceptions of the Cnidian School (about three hundred years B. C.) were unquestionably more readily to be understood than the general conceptions of the Cosan School, so that within the lapse of a century they dominated, at the time when Alexandria became the most important centre of medical learning. Here Herophilus, a student of Praxagoras of Cos, and Erasistratus, a student of the Cnidian Chrysippus, taught, so that reason founded on experience—dogmatism—was still in honour at first, but their disciples soon exaggerated the doctrines of the masters so that Philinus and at a later date, Serapion, the founder of empiricism, upheld that in medicine, reasoning was time lost.

This tendency, notably attenuated, is to be found in the writings of the Methodists. Asclepides, of Bithynia, (100 B. C.) who arrived in Rome in the time of Pompey, was the first whose opinions have reached us, thanks to Aurelianus. The promoter of solidism, he rose against the hippocratic theory of disease, crises, and critical days: *"neque inquit esse in passionibus statos dies quos crisimos appellant. Etenim non certo aut legitimo tempore aegritudines solvuntur.* Themison was his disciple, and developed his ideas. To him we are indebted for the theory which attributes all diseases to relaxation and contraction. However, he must have perceived the insufficiency of these purely solidist interpretations because between the *strictum* and the *laxum,* he admited a *mixtum.*

Celsus is the mouthpiece of the Methodist sect and I would point out that he stoutly denies the influence of the critical days: *"Vernum, in hic quidem, anti quos tunc celebres admodum pythagorici numeri fefellerunt."* (Lib. III, Cap IV.) On the other hand, Celsus's fourth book is devoted entirely to the subject of pyrexias and no mention of crises is made.

Methodism, that is to say, solidism, also gradually assumed considerable importance and towards the end of the first century of our era and the commencement of the second, it was brilliantly defended by Soranus, of Ephesus. The hippocratic conception of disease, with crudity and coction of the crisis, became profoundly disturbed, until a man appeared who again took up the ancient doctrine, developed and systematized it, and then made it triumphant for fifteen centuries, although he had fashioned it after his own ideas.

In point of fact, Galen (*De crisibus,* lib. III, cap. II) had notably changed the doctrine of crises. According to him, a crisis is *"sola subita ad sanitatem conversio,"* in order to exist, it must be preceded by a manifest disturbance of the economy and to reveal itself *"per manifestas quasdem excretines aut effata dignos abcessus."* Nevertheless, Galen admits the occurrence of imperfect crises in which a sudden change of the morbid evolution does not terminate in recovery. Consequently he enjoins that a crisis must be preceded by a bodily disturbance, that it must be sudden in occurence, and give rise to profuse evacuations. Therefore, it is clear that he distinctly separates lysis, by which process a disease slowly retrogresses without any marked evacuations.

It is evident that this conception is far less simple and less synthetic than that of Hippocrates. Entering still deeper into the study of details, Galen developed the doctrine of critical days to an excessive degree. The critical days are those on which the crisis should take place. They were divided into: 1, the decreed or principal critical days; 2, the indicatory critical days, and 3, the intercalary critical days. The principal days were those on which the crisis usually occurred, namely, the seventh, fourteenth, twentieth, or twenty-first days of the disease. All acute diseases ended in forty days and frequently much sooner, so that their ordinary evolution was divided into weeks. The indicatory days divided the week into two parts, and announced what was to occur during the following quaternary. For example, the fourth day of the week was the index of the seventh. Hippocrates says in his *Aphorisms*: "Those [diseases] which should be judged on the seventh [day] present a white hypostasis in the urine on the fourth [day]." This likewise applies to the eleventh, seventeenth, and twenty-fourth day.

The intercalary or provocative days were those on which a crisis irregularly took place. They were to be feared because frequently they announced a relapse. These days were the third, fifth, sixth, ninth, thirteenth, and nineteenth. Finally, the remaining days were termed empty or nondecretal, because a crisis rarely occurred on them. These days were the second, sixth, eighth, tenth, twelfth, sixteenth, and eighteenth of the disease. They were also called medicinal days, because, being inconsequent in so far as the disease was concerned, they were of importance to the physician as he could interfere therapeutically.

In Corvisart's edition of Avenbrugger it is stated: *"Ils sont pour ainsi dire les jours de l'art qui n'a presque ancun droit sur tous les autres, puisqu'il ne lui* [the physician] *est jamais permis de déranger la nature qui partage son travail entre les jours critiques."*

Among the latter, the sixth day was, for Galen, especially inauspicious, while the seventh, on the contrary, was the most favorable: *"Nihi quidem frequenter in mentem venit septimi dici naturam regi assimilare, sexti vero tyranno. Ille siquidem providet tanquam bonus aliquis princeps iis quos judicat ut vel supplicii partem adimat, vel illustret victoriam."*

This faith in the happy power of the number seven was deeply rooted in the minds of the ancient

physicians. It is referred to by Solon and invariably the writers of ancient times exerted themselves to prove its virtue.

Dulaurens, in his *Traité des Crises* (Livre II, chap. IX) says: *"Les Aegyptiens, Chaldéens, Grecs, et Arabes, ont laissé beaucoup de choses par escrit touchant l'excellence du septenaire que je fais i cy á escient pour ne charger le papier de telles badineries, qui soubs ombre et pretexte des nombres ont la vogue parmy le monde. Car qu'importe au sage s'il y a sept pleyades, si les deux Ourses sont faictes chacune de sept estoilles, s'il y a sept merveilles au monde, s'il y a sept planètes, sept hyades, si la lune a sept faces, si les septentrions grandes et petits sont sept, si les changements de la voix sont sept, s'il y a sept movemens naturels, si les choses qui se voyent sont sept, s'il y a sept aages, sept voielles en la lanque grecque, sept sages, sept metaux, si le Nil a sept bouches . . . si sept arts liberaux, sept causes des actions humaines, sept villes qui querellent pour l'extraction et naissance d'Homére, etc. . . ."*

The opponents of Hippocrates contested his moderate opinions in respect to critical days. Galen made still more exaggerated assertions and he especially should be censured for allowing himself to be guided in his system by the vagaries of Pythagoras. Nevertheless the galenic doctrines were accepted by the Islamic physicians, who still further accentuated the superstitious aspect. Galen referred to the influence of the moon on crises, while the Islamic writers combined it with all the other astral bodies.

It was the Galenism perverted by the Islamic physicians and mixed with astrology which, supported by the principal authority, reigned in Europe throughout the medieval ages, and even later, because even at the beginning of the seventeenth century, David de Planis Camp (1) dedicated to the Queen, mother of the King, a *Bref discours des crises, ou il est monstre comment l'on s'abuse au jugement d'i celles ne cognoissant le movement des astres.* (Paris, 1640.)

"Les praticiens de ce temps," says J. B. Aymen (2), *"ne jugent les maladies, qu'après avoir examine avec attention la place qu'occupaient les astres soit dans les premiers moments de la maladie, soit dans les jours dans lesquels ils prescrivaient les remedès; la superstition fut même si avant que le medicin n'eut pas cru être en état de querir personne, s'il n'eut connu dans quelle position etaient les planètes au moau moment de la naissance du malade."*

(To be concluded)

Contributions to the Science of Medicine

Lord Lister

Surgery was revolutionized by Pasteur and Lister. The French chemist, the true founder of bacteriology, although not a medical man, did more to change the prevailing conceptions and practice of medicine and surgery than any man, and Lister, as far as surgery is concerned, carried the ideas of the master to definite conclusions. At the unveiling of a memorial to Lister in Kelvingrove Park, Glasgow, on September 17th last by Sir Hector Cameron, emeritus professor of surgery in the University of Glasgow, and one of the last survivors of Lister's house surgeons, he made an interesting speech a part of which was so apt that it will be quoted here. In giving an account of the surgery class in the University of Glasgow in 1862 when Lister was professor, "one of my fellow students," he said, "was Frederick Trendelenburg. Some years ago in a letter which I received from him, he observed that while we all regarded Professor Lister with great respect and admiration, none of us could foresee that he would one day change surgery from the very bottom." This was a just remark.

Lister was a conspicuous example, of which many have been afforded in history, of the truth of the old proverb that "a prophet hath no honor in his own country." It is curious that pioneers in every sphere of endeavor are almost universally distrusted and pioneers in medicine perhaps the most distrusted. In Great Britain the medical profession are conservative and bound by tradition and it takes time for new theories to take root. Thus it is not astonishing that for long Lister was regarded as wrongheaded, and the imperfections of his original primitive methods are even yet pointed to as illustrating the exaggerated nature of his claims.

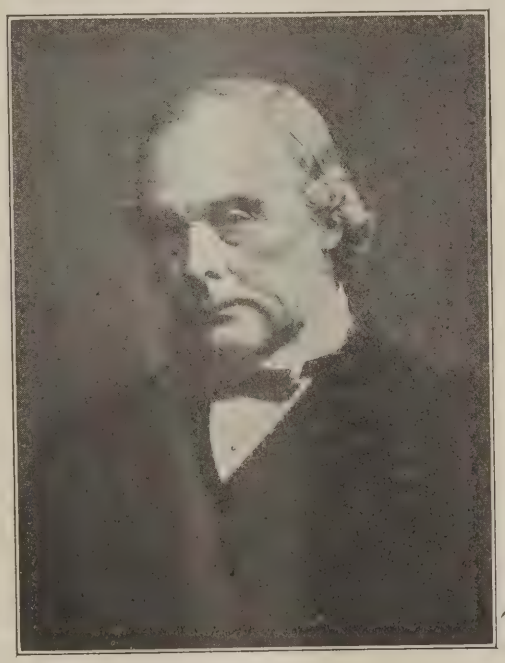
Surgical skill was at a high standard when Lister was a student; he was born in 1827, and witnessed the first operation in 1846 under the general anesthetic by Robert Liston, that wizard of the knife. At the same time, despite the marvelous dexterity and coolness of the surgeons, a large proportion of the patients who underwent major operations were carried off by the ravages of erysipelas, pyemia and hospital gangrene, while the dread of such happenings restrained frequently surgeons from operating when by so doing life might have been saved or crippling prevented. Liston taught the necessity for strict cleanliness and for combating the germs of infection in the operating theatres and in the surgical wards.

His student's life was passed at University College, London, from 1844 to 1853. He was born of Quaker parents and educated at Quaker schools. His father was engaged in business, but was a man of high scientific attainments, a Fellow of the Royal Society of England, and who made great improvements on the achromatic microscope. According to Sir Rickman Godlee, whose life of Lister is the most reliable, he had exceptionally good abilities, a retentive memory, the power of concentration, and unlimited patience and enthusiasm in investigating every doubtful question and pursuing each investi-

gation to the bitter end. In short, he was fully endowed mentally and temperamentally with the qualities which go to make the successful scientific investigator, and lastly he was well enough off not to be under the necessity of earning his daily bread and thus could spare the time for research with a mind free from money worries.

In 1853 he left London for Edinburgh where he found a larger and in many respects a better school of medicine than at University College. At that time Mr. Syme was the great surgeon there, probably the greatest surgeon of the day. Lister stayed on in Edinburgh first as house surgeon and later as assistant surgeon to the Royal Infirmary and extramural lecturer on surgery. In 1856 he married Syme's eldest daughter.

His first serious scientific studies were concerned with inflammation, a subject on which he wrote and published several important papers, becoming well known throughout the world for his scientific work. He left Edinburgh to take the position of Regius Professor of Surgery in Glasgow University, where he spent nine years and did most of his best work. 1865 may be termed the birth year of antiseptic surgery although it was not announced publicly until 1867. At that time hospitals of Great Britain and indeed of the civilized world were in such an infected state that in Scotland and in England it was seriously contemplated to destroy the hospitals wholesale in order to replace them by villages of temporary huts. However, in 1860 or thereabouts, Louis Pasteur solved the problem of the cause of decomposition.



LORD LISTER

In writing concerning Lister it is difficult to fix with any degree of exactitude his place in history, and, in fact, his work is so bound up with that of Pasteur that in writing of Lister's discovery, it is not easy to avoid bringing in Pasteur. The discovery was entirely due to the results of Pasteur's investigations on decomposition which showed that it was a form of fermentation and subject to the same laws caused by microorganisms conveyed by the air. His first attempt to put Pasteur's discoveries into practice is described at length in an "epoch making" paper on a new method of treating compound fractures, abscesses, etc, published in the *Lancet,* 1867, vol. I, pp. 326, 357, 387, 507; vol. II, p. 95. Lister's idea at the time was that the air was teeming with the particular germs which caused decomposition and his attention was concentrated upon devising means to destroy the germs in the air to prevent them from reaching the injured parts, and to destroy them in these parts, and he paid no heed to their other habitats. Also his agent for accomplishing this purpose was crude carbolic acid, a far from ideal medium for the purpose. At the time, it may be recalled, little was known of bacteriology and nothing of the defense of living tissue. Therefore, although the method was primitive, it introduced the principle of aseptic surgery, which together with the employment of anesthetics has revolutionized surgery regarded from all aspects.

The paper made a deep impression upon the surgical world in spite of the fact that its true inner significance was grasped only by the few, namely, that it heralded the dawn of a new era of surgery and that the treatment was applicable to all wounds.

Between 1867 and 1870 Lister improved his methods and his success in the previously unhealthy Glasgow wards under his charge was so striking that the advantages of this form of treatment seemed selfevident. And yet British surgeons refused to be convinced, indeed the majority of them perhaps, became definitely antagonistic. The reception of the doctrine abroad or, at any rate, in Europe was in marked contrast to the frigid or inimical reception in his native land. Unbiased by personal considerations, the surgeons of the Central European Empires and of Scandinavian countries, where the state of the hospitals was worse than in Great Britain, were willing to give the new treatment a fair trial and, on the whole, were cordial towards it.

Little progress was made in France or Italy and the same may be said of America. In truth, in these countries this new departure from the beaten track was regarded as an experiment not to be followed until a distinct verdict in its favor had been delivered in those parts of Europe in which it had been employed. In 1869 Lister was appointed to the chair of clinical surgery in the University of Edinburgh, a position he held until 1877. This period was the most brilliant of his career. Shortly before he left Glasgow his father died, and in 1870 Syme died.

In Edinburgh Lister had the largest class in Great Britain, and in many ways Edinburgh was an ideal place for launching and establishing a new system of surgery. It lacked the distractions of an immense city like London, and what was more to the point there was no opportunity for one's time being almost wholly taken up with the exigencies of a huge private practice, a catastrophe which has overtaken many brilliant medical men who in more favorable circumstances might have given to the world discoveries of inestimable value. Lister devoted all the time he could snatch from his duties to experimental research, which was largely concerned with improving and modifying his methods and in seeking the perfect catgut ligature.

Bacteriology was emerging somewhat rapidly from its swaddling clothes and, of course, with increase

of knowledge in this direction Lister soon found that the treatment of wounds by his methods was by no means so simple as it first appeared and he experimented widely and published the results. As Godlee has pointed out, it should be borne in mind that aseptic surgery as it is now understood was from almost the first, Lister's ideal, and that he tried to adopt it himself as early as 1865 and on later occasions, but did not persist with the attempt because in his opinion antiseptic treatment was equally efficient and carried out more easily by far.

Von Bergmann was the scientific father of the aseptic technic and its successful employment was due mainly to Metchnikoff and Almroth Wright and their followers.

After he had spent eight of the most active years of his life in Edinburgh he accepted the chair of clinical surgery at King's College, London, succeeding Sir William Fergusson. The main opposition to his views was in London, and while it was perhaps an advantage for Lister to be able to promulgate his views in the enemy's stronghold, on the other hand there were decided drawbacks. The hospital was small and he did not, as in Edinburgh, attract a large class. The London student was cold and indifferent to views which had not been generally accepted. He was in London for longer than thirty years, during the first half of which he was engaged in hospital and private practice and he continued his laboratory researches which were given over mainly to the search for a perfect catgut and a perfect gauze. In 1853 he was given a baronetcy and by degrees he took his rightful place as one of the leaders of the British medical profession, the old jealousies and heartburnings of the London surgeons having disappeared gradually.

In 1893 Lady Lister died suddenly in Italy, and owing to the age limit he retired from the surgeoncy of King's College Hospital. Consequently at the age of sixty-six he found himself childless, without hospital appointment and without private practice. Laboratory work, too, was almost laid aside, partly because the loss of the wife, who had been his faithful helper and amanuensis, had largely killed his interest in it but chiefly because, except for the question of catgut, he had made all the improvements possible in the dressings. As for bacteriology it had become and was becoming so complex a subject that in order to keep pace with its progress a person must be continually studying it. He threw himself into his public duties, which were many, with energy. He was appointed foreign secretary to the British Royal Society, and in 1895 he succeeded Lord Kelvin as president. His annual addresses showed how closely he kept himself in touch with the leading scientific questions of the day, and as Godlee says should be read by anyone who is disposed to regard him as a man of one idea. In 1896 he was president of the British Association.

In 1897 he was made a peer and took an active part in the House of Lords in debates on public health and sanitary science. In 1900 he delivered the Huxley Lecture, and in 1901 took part in the Tuberculosis Congress.

The Huxley Lecture is given every two years at Charing Cross Hospital. Michael Foster, the great English physiologist, gave the first. Virchow gave the second, and Lister the third. After the Tuberculosis Congress at which Koch made the announcement that bovine tuberculosis is rarely if ever transmitted to human beings, he passed almost wholly from the public eye. He received numerous honorary degrees and other distinctions and there were celebrations of his eightieth birthday at home and abroad. He had a serious illness in 1903 from which he really never recovered, and the last years of his life were devoid of incidents worthy of record. He died on February 10, 1912, nearly eighty-five years of age. There was a public funeral in Westminster Abbey and he was buried by the side of Lady Lister in the West Hampstead Cemetery.

Like Pasteur, without whose researches Lister's discoveries would have been impossible, he lived long enough to enjoy the fruits of his labors and to know that the value of his work was recognized.

In 1875 Lister made a tour of Europe and met, especially in Germany, with an extraordinarily enthusiastic reception. In the following year he attended the meeting of the International Medical Congress in Philadelphia, where he likewise received an extremely warm welcome. Up to this time, however, his teaching had taken no deep root in America. His presence, his addresses and demonstrations appeared to kindle an intense interest in the matter, and from that time on American surgeons studied and practised the principles of Lister with zest.

In person Lister was a well built, muscular man, about five feet eleven inches in height, fond of active exercise and of swimming and skating. He was a charming companion, although when older he became somewhat ceremonious, inspiring a certain amount of awe. He was the subject of the unbounded love of his Scottish students; to them he was always "the chief," and as the Scotchman goes to every corner of the earth, they carried his fame and teaching everywhere. While by no means eloquent he was an effective speaker and impressed his hearers by his obvious earnestness. He was a good linguist, knew French and German sufficiently well to make public speeches in those languages, and had more than a nodding acquaintance with Spanish, Norwegian and Dutch. He was a good artist so far as anatomical, pathological, botanical and microscopical drawings were concerned. He appears to have had no fads to interfere with his scientific work. He was a sound operator, careful, methodical, thorough and slow. He introduced some new operations and invented some new instruments. He was a resourceful experimenter. His apparatus was simple, most of it he made himself and the rest he designed. He was essentially a serious man and undoubtedly his Quaker upbringing had a great influence on his attitude towards life.

It is too soon and would be futile at the present time to attempt to forecast what the verdict of history on Lister will be. As Godlee points out it is more than likely that his originality will be doubted by some captious critic because he only worked out the discoveries of Pasteur. It cannot be denied by the most captious critic that he was the first to grasp its significance with regard to wound treatment and that through him aseptic treatment has reached its present high standard, which has made surgery comparatively safe and has rendered possible operations

which could not even have been attempted under preaseptic conditions. He pointed and showed the way which others have followed to the great and lasting benefit of suffering humanity. The names of Lister and Pasteur will go down through the ages as men who robbed surgery of many of its worst terrors.

The Siamese Twins of Espanola (The First Known Postmortem Examination in the New World).—A. Pena Chavarria and Dr. P. G. Shipley (*Annals of Medical History,* September, 1924) give us the history of perhaps the only postmortem examination ever conducted to study the soul of the deceased, and what is believed to be the first pathological examination made by white men in the western hemisphere. It antedates by more than a half century that performed on the dead scorbutic soldier by Cartier's surgeons at Stadcona. The account was found in Oviedo's *Historia General y Natural de las Indias.*

Gonçalo Fernández de Oviedo y Valdés was born in Madrid in 1478. In his early boyhood he served as page to the nobility of Aragon, and at thirteen became a member of the household of Ferdinand and Isabella as the companion of their son, Don Juan, and so came in contact with the most brilliant court of Europe, with its splendid festivities, gorgeous tournaments and jousts, and chivalric and heroic traditions. Here he met Columbus, of whom he writes, "His memory shall have no end, for when all that is written and shall be written shall have perished from the earth, heaven itself shall perpetuate this famous story."

Driven by dissatisfaction with the conditions which existed in Spain, Orvieto set out to wander over the world, practising the profession of letters and of arms. He made the acquaintance of Titian, Da Vinci and Michael Angelo, of Sanazzaro the poet, and of Pontano, and carried on his studies. After a number of years he took passage for the Americas to record the history of the world, a project he had conceived in 1492. On the 12th of June in the year 1514, the first historian of the western hemisphere saw the land. In October of the following year he returned to Spain, having begun his history, and carrying as presents for his sovereign six cannibals, the first sugar from that part of the world to reach Europe, cassia fistula, six Indian maidens, and thirty parrots.

On a second voyage he was very ill with what was described as "acute continued fever" (perhaps malaria) and was believed to be dying. He had asked a sailor to destroy a blanket that had been used for him during his illness, and the man was proceeding to do so when Oviedo's servant, who had not heard the request and who thought his master unconscious, called out, "Don't take that! If you do, we shall have nothing to wrap around him when we throw him overboard." Oviedo heard the remark and rose in anger from his bed declaring, "I shall not die at sea nor shall I, I trust, be buried anywhere save in consecrated ground." His recovery dated from that moment. He made the voyage to the New World and back twelve times. During the latter years of his stay in America he served as captain of the fortress and city of Santo Domingo on the Island of Española. He did not live to see the whole of his great history published. Death came to him in Valladolid in 1557, and smote him, pen in hand, in his seventy-ninth year. His biographers write of him: "He was omniscient in the knowledge of his day, and his book is abundant evidence of that fact. He wrote ably of the customs and habits of the savage people he found about him, and, though neither a botanist nor an entomologist, his descriptions of the fauna and flora of the New World were above reproach. He was no physician but he has left good records of some of the diseases of the tropics. He recorded the case history quoted below, clearly and thoroughly in excellent language and style, missing no important detail."

The case recorded by Oviedo was that of a double monster born to a woman of Santo Domingo, which he was stimulated to report by reading the case of the two headed boy of the Arno described by Fierenze.

These Siamese twins, which were females, were seen by Oviedo, in the company of the important officials, priests, scientists and residents of the vicinity. The children were joined from the umbilical region upward to a point on their thoraces just below the breast. The writers quote the detailed description given by the historian, which is a testimonial to the fact that he must have been well acquainted with much of the medical knowledge of his day and also with the best medical literature of that period.

The twins died on the eighth day of their life, one shortly before the other. Their baptism was a great problem to the good priest of the town, for he could not tell whether this curious body housed one or two souls. However, he very cleverly got over the question by administering the ritual of baptism for those concerning whose previous baptism there is doubt. But apparently he was too conscientious to be satisfied by this begging of the question, for the dissection of the twins after their death was done largely for the purpose of resolving the doubts concerning whether there were one or two souls, no attention being given to cause of death. This was probably the reason why the parents consented to an autopsy, for the feeling against medical investigation was much more intense then among the laity than today.

The full description given by Oviedo, in brief, amounts to saying that the twins had in common only the umbilicus and the liver. Our writers comment: "The holy church at that time was not giving much consideration to the liver as the seat of the soul and the doctrine of the omphalopsychists was damnably heretical. But there was more to be said as to the blood being the seat of the soul since according to the Vulgate *anima omnis carnis est in sanguine,* which is a definite, precise, and authoritative statement. . . . But we confess that we feel as did Oviedo and his friends, that for practical purposes the decision as to individuality was best made on physiological rather than anatomical grounds. The church allows that soul and body separate at death and since, beside carrying on separately the visible functions of life, Johanna and Melchiora died separately, the conclusion that they were animated by two individual souls seems justified. . . ."

GENIUS

The defining of genius seems as difficult as the defining of life, of which it is the flower, yet the definitions that have been given are not diverse, even if they are partial or indefinite. The latest essay in this field is that of Bernard Shaw in the preface to his *Saint Joan.*

That Joan was a genius there is no denying, and she has won the respect and admiration of geniuses of a higher rank than Shaw. His definition reads: "A genius is a person who, seeing further and probing deeper than other people, has a different set of ethical valuations from theirs and has energy enough to give effect to this extra vision and its valuations in whatever manner best suits his or her specific talents." Certainly he has hit the point in his first phrase, for the genius has no more money making or fame finding end in view, nor does he work from hand to mouth—from day to day—but with a far distant goal. It is true that he may need to do hack work to fill his belly withal, and he may even lapse, at times, near the commonplace. Beethoven wrote much, for him, ordinary music, but he appraised these compositions accordingly. Even the best critics cannot tell some of the works of Raphael or Michel Angelo from those of their contemporaries and assistants, and the same is true of the writings of Dumas and other authors. Nevertheless, these lapses only make us recall that the genius is human. If he were not, he would have no appreciation whatsoever.

Your man of genius does not necessarily do things easily. A Mozart may turn off finished musical gems in a sitting, whereas an even greater composer got his ideas in the rough and toiled and sweated over them until they were scarce recognizable in the polished product. Indeed, genius has been defined as "capacity for work," though this is by no means a comprehensive definition. Many people toil, but never get anywhere above the level. There must be energy, however, and our great men have, as a rule, been persons of great vigor. Our Leonardos, Michel Angelos, Tennysons, Brownings, Beethovens, Brahms, Scotts, Hugos, Carlyles, Washingtons, Napoleons, were men of immense bodily powers.

Genius has been more than once defined as "health" nor was the definition hit upon by a man especially interested in furthering hygiene. There have been unhealthy men of genius, but they would have been greater men of genius had their bodily frailties not hampered them, and they have often complained bitterly on this account. Certainly, with few exceptions, the man of genius has been immensely interested in his own health and the best essays on respect for the body and its needs were written not by medical men nor professional hygienists but, on the side, by great geniuses in other fields.

This leads around, again, to Shaw's idea that the man of genius is on another plane, a plane which has great respect for the body—for the good condition of the machine—because it is recognized by him as necessary if he is to "give effect to this extra vision" which Shaw included in his definition.

Life is indefinable, genius is indefinable, and, while they express themselves materially, they are far and away something more. The genius is truly inspired and, if so, there is some inspiration in those who can respond to, and appreciate, him in some measure. Joan of Arc was certainly inspired, and a genius, and we like Shaw's admission that there is a fountain of inspiration continually flowing in the universe which is "more obvious than electromagnetism." Such an expression is delightfully refreshing in this machine made age of ours.

ARTIFICIAL IMMUNIZATION AGAINST DISEASE

The value of vaccines and sera is still a question which requires much more clinical experience and proof. The potentialities and possibilities of the methods are immense and if brought to fruition would almost abolish disease. Prophylactic vaccination in certain specific infections is of acknowledged value while in certain other diseases it has apparently failed. In maladies of a nonspecific character the possibility of adequate protection by such methods may be considered in the terms of Scottish law as nonproved.

There is considerably greater confidence in the prophylactic rather than the therapeutic use of vaccines. In diphtheria or tetanus the passive immunization with specific serum has won a great triumph as the unique curative or prophylactic measure in the treatment of diphtheria and tetanus and leads to the hope of further success in the same direction. At a meeting of the London Association of the Medical Women's Federation held at the Elizabeth Garrett Anderson Hospital on May 13th last, Dr. Iris Fox discussed this subject at some length. She expressed her wholehearted belief in the future of artificial immunization and thought that we had here a powerful, perhaps the most powerful,

weapon against disease, but had not yet the knowledge to use it properly. For example, there was the widest variation in the doses given and the reactions arrived at. In the case of prophylactic inoculation against the enteric fevers the large initial dose was given of five hundred million Bacillus typhosus, with two hundred and fifty million each of Bacillus paratyphosus A and B. An example of a higher initial dose was the method of inoculation against pneumonia employed by Spencer Lister, who gave a first injection containing six thousand million each of four different pneumococcal strains.

Every kind of vaccine had been, and still was being, given on a large dose system in which a slight or moderate constitutional reaction was desired, and, on the other hand, in comparatively minute doses, aiming at immunization without the production of any general disturbance. Miss Fox thought, however, that there was an increasing tendency to use small doses in treatment. There was just as much difference of opinion concerning the interval between injections and the importance of the negative phase. It was difficult to determine, it might be added impossible, in our ignorance of the immunizing processes of the body. Laboratory attempts at exact measurement of immunity production had been of no more help than had vague clinical impressions as to the value of this or that proceeding. Protection against or cure of disease in the animal body was not always proportionately indicated by a high serum content of antibodies such as agglutinins. It seemed likely that specific antibody content was not the only factor in immunity, and much work and probably considerable alterations in our conception were needed before specific therapy could be properly controlled. Miss Fox dealt briefly with active immunization against diphtheria, which had passed the experimental stage and was being practised with the greatest success in America. Also with the typing of pneumococci and with the beneficial results, in the Rockefeller series of cases, of the specific antiserum in Type I cases.

Dr. Mary Cowan has been making investigations as to the rough and smooth varieties of the hemolytic streptococcus and to the possible clinical application of this work. Dr. Mary Cowan at this meeting said that from a single strain she had been able to isolate a rough and a smooth type of hemolytic streptococcus of which the smooth was virulent and the rough was not. She tried to immunize mice and rabbits, and in mice was able to give immunity by a serum produced from the rough to those infected with the smooth variety. In rabbits this was only possible in a small percentage. When using a smooth strain alone she had sixty-six per cent. of successes.

The serum of protected rabbits gave great variation in agglutinin content, some animals which had agglutinization of a very low titre lived, and others with a high titre died. No relation was found between agglutinins and useful antibodies. The progress being made towards improving methods of immunization against disease can be described as encouraging. Knowledge is lacking in certain essential points and until this knowledge is complete or more or less complete, success can be but partial. Workers are groping if not in the dark, at least in a dim light, and have a great deal of clearing away to do before full effulgence is attained. It is not definitely known as yet whether immunity against certain diseases is developed in the blood stream or in the cells of the tissue especially attacked by the causal organism.

Besredka and his collaborators affirm that it is in the cells of the tissue attacked and that therefore special methods of vaccine administration is indicated. This statement, perhaps, applies more particularly to the filterable viruses, certain groups of which evince well defined predilection for certain tissues. In any event, these are points which should be cleared up. In the efforts of research to find out means for protecting by artificial immunization a great deal may be learned by studying certain diseases of animals, which exhibit characteristics to diseases in human beings, and to this end the study of comparative pathology and comparative medicine generally is to be commended. Cooperation in research work between medical men and veterinarians seems likely to be attended by the happiest results.

MEDICAL WORK IN THE VETERANS' BUREAU

Dr. Palmer A. Potter since 1920 has, from a medical point of view, reviewed or supervised the reviewing of many thousand folders of the claimants of the U. S. Veterans' Bureau. These present a fertile field for the compilation of statistics. Stress of routine work, up to the present, has made impossible a collection of data sufficient for scientific interest. Leaving aside actual statistics, however, a number of facts have presented themselves to those who review the medical histories covering a period averaging five years. The number of cases coming under immediate observation in the district office in New York city is about one hundred and ten thousand, although the number under observation in Washington previous to decentralization in the summer of 1921 approximated eight hundred thousand.

It should be understood that the medical histories alone were observed in the majority of cases. These histories cover a period from the beginning of military service to the present and include reports of

examinations made at induction by the local draft board and at camp, the medical records during service, as noted on Form 52 and Form 55 of the Army, the examinations at discharge and the examinations made at intervals after the filing of claim for compensation. This editorial concerns only general impressions founded upon the review of many thousands of such medical histories and is not concerned with statistical data or scientific deduction.

One thing noted is the frequency with which so-called functional murmurs with no enlargement, definitely diagnosed as such at enlistment or induction, later develop into true valvular disease with definite enlargement of the heart. This is of particular interest in view of the orders issued by the Army in August 1918—as will be recalled by those who were in the service—that a murmur at the apex without enlargement did not disqualify for the service and by inference was considered neither a disease nor a disability and more or less normal in a young man. The exact reverse of this is also frequently observed. A considerable number of exservice men who carried in service a definite diagnosis of valvular heart disease and were discharged with it, and in some even because of it, show on later examinations no trace whatever of any cardiac disease. This point is being taken up and investigated in detail by one of the physicians connected with the U. S. Veterans' Bureau.

Another thing noted, particularly in Washington, where examination reports, not only from the whole country, but from all over the world, were reviewed, was the proneness of examiners to make a diagnosis of myocarditis in young men, on what seemed, on a complete review of all the evidence, to be insufficient grounds. It appears to be the belief among the profession throughout the country that myocarditis is easily diagnosed and, even in young people, of rather common occurrence. The diagnosis of an hypertrophy of the heart made on physical signs alone, is frequently not borne out by an x ray either preceding or subsequent. This is so true that the diagnosis is practically never accepted in the absence of confirmatory x ray.

The afterresults of gassing are, or were, the subject of much, and particularly newspaper, discussion. The popular impression as to these possible results differs widely from the accepted scientific conclusions. Popular opinion ascribes every possible ill to gas. Scientific conclusions, founded in large degree upon the examinations of gassed men made at the time of discharge, are that gassing leads to practically no later disability.

Those who review the subsequent histories of severely gassed cases do not agree with either of these. The impression is obtained, although as explained previously no statistics can be supplied, that men severely gassed—and by severely is meant those with a medical history of a month or more in the hospital—frequently show for one or two years after discharge the evidence of well marked persistent bronchitis, with an appreciable number developing emphysema or asthma. The Medical Division of the Chemical Warfare Service has shown that there exists no basis for the belief of relationship between gassing and pulmonary tuberculosis. This has been carefully investigated and the results appear conclusive.

Until about 1922 a considerable number of severely gassed patients showed on examination some apparently functional heart disturbance. This was noted particularly in the cases reviewed in Washington during 1921 and 1922. The irritability, tachycardia, or whatever it was, does not seem so much in evidence as time passes, judging from the cases reviewed at present. One effect of severe gassing that has not been touched upon previously is the possibility of gastric or duodenal ulcer being due to this cause. Potter has noted fifty-one cases in which this relationship appears possible, although, of course, by no means proved. All of these cases had in their Army record a history of hospitalization for gassing. During the course of this hospitalization and in some cases bearing the diagnosis coincidently at admission, severe intestinal disturbance developed. Of the many cases having a combined diagnosis of gassing and intestinal disturbance, fifty-one later developed in the course of a year or two, either gastric or duodenal ulcer, and in one case both. The diagnosis in all these cases was proved by x ray or operation. The ulcers probably would have been formed without the preceding gassing, possibly they would not. Persistent intestinal disturbance beginning, so far as the history shows, at the time of severe gassing, with a later development of gastric or duodenal ulcer, leads to the supposition that there may be some relationship between the two. The late Dr. E. A. Spitzka, who had the opportunity of reviewing many of these histories, believed, as does Dr. Potter, that between the gassings with coincident severe intestinal disturbance, and the later ulceration, there possibly may exist the relationship of cause and effect.

The frequent difficulty of the differential diagnosis between pulmonary and abdominal conditions, is, of course, generally admitted. It is particularly difficult in children to distinguish between pleurisy or pneumonia at the right base and true appendicitis. One outstanding fact noted in reviewing these many medical histories is the frequency with which cases of appendicitis or other abdominal condition later show a definite pulmonary tuberculosis. A large number

of cases of active pulmonary tuberculosis bear in their folders the report of a preceding operation for appendicitis. Frequently, with no history or complaints referable to the chest, a moderately advanced, active pulmonary tuberculosis is discovered following operation for some chronic abdominal condition. Whether the appendix was actually diseased in these cases, the history, of course, does not reveal. All that these folders show is the history of abdominal complaints, the notation as to the operation for appendicitis, followed, after a varying interval, by the diagnosis, borne out by physical findings, of active pulmonary tuberculosis.

Patients are occasionally met having a medical record in service of appendectomy, but showing a recurrence of symptoms after discharge. Eighteen cases of this kind have been found by x ray or operation to have stone in the right kidney, two cases showing the presence of calculi in the left alone. There is, of course, nothing new or startling in the knowledge of the difficulty of distinguishing between the two conditions. It is thought, however, that the realization of the comparative frequency of the possible error and of the necessity for a complete uranalysis in acute appendicitis may be of aid.

We also note the frequency of recurrence following operation on varicose veins. The histories do not show what method of operation was used. Many men now with well marked varicose veins have, on their medical history, a record of having been operated upon for that condition, either while in the service or since discharge. The impression is obtained that permanent recovery, as a result of operation for varicose veins is, to say the least, rather rare.

In this connection, an unusual case, the records of which have come under observation, is mentioned. This man was operated on for varicose veins while in service. Since discharge the varicosities have returned and now involve not only the legs but the veins of the abdomen, chest, axillæ and forehead. The liver is apparently normal in size and there is no evidence on x ray of mediastinal tumor or other source of portal obstruction.

The Veterans' Bureau has a valuable opportunity to follow the psychic effects of penetrating wounds of the skull, and one of the neuropsychiatrists connected with this service is collecting data covering this point. This article, however, is concerned only with the general impressions obtained from the review of many medical histories. The gradual unfolding of a true disease or disability with definite diagnosis and physical findings from its early beginnings and varying diagnoses and the observations of the end results of apparently unconsequential occurrences or complaints may be of interest.

THE INTESTINES

The book of anatomy, large as it is, is not yet finished. Indeed, it is stretching its binding nowadays in a lively fashion, for there seems to be no standard body, as we have been led to believe, and the variations are far more than those of the shape of a bone, the attachment of muscles or branching of bloodvessels.

John Bryant has recently published a further study of the development of the intestine which is interesting. He finds the most striking characteristic of this organ to be the extreme variation in length which is evident at birth and which begins as early as the fifth month of fetal life. In his large list of 242 cases there was an average length for the small intestine of twenty feet and nine inches; and for the colon, five feet two inches. (These measurements do not include the duodenum or rectum.) The minimum length was three metres for the small intestine and one metre for the colon, and the maximum lengths were 8.5 metres and 3.25 metres. It was pointed out by Treves some time since that the length of bowel is independent of age, height and weight, and these findings of Bryant confirm this opinion as to height and weight. Bryant found, in his cases, that at ten years of age practically all children had already attained a small intestine longer than the minimum length compatible with prolonged adult life, though they had not acquired much over half the corresponding length of colon. The small intestine is longest in relation to body length at birth and is proportionately shorter in adult life. The colon, on the other hand, increases in length and, between twenty and eighty years, becomes twenty per cent. longer.

As Bryant points out, we proceed from a carnivorous type of bowel to a vegetarian type, though whether function here makes structure, cannot be safely asserted. It would be interesting to compare changes in relative length, which may take place with increasing age in lower animals. After the tenth year the growth of the human small intestine is chiefly one of increase in calibre.

The statement has been made that people of the heavy, apoplectic type have a relatively long intestine and are therefore nourished with comparatively little food, while the slender or tuberculous type have a relatively short intestine and are difficult to keep in good flesh. Bryant's cases do not support this view. At any rate, his twenty-eight tuberculous cases had an intestine and colon of normal length. A shorter intestine and colon was, however, demonstrated in twenty-eight cases of carcinoma. The tuberculous is often a fairly good feeder, the cancerous person is not, after development of the cancer is well under

way. Is the relatively short intestine in the latter due to lack of function? Such a shortening could hardly occur in a few years. There are many interesting things yet to be learned about the food canal.

RICKETS IN AN ITALIAN DISTRICT OF NEW YORK

While the New York Association for Improving the Condition of the Poor was conducting its health campaign in the Mulberry District, it was found that fully twenty-five per cent. of the children of preschool age were suffering from serious orthopedic defects, largely the result of rickets in early infancy. In the opinion of the examining physician, Dr. Louis C. Schroeder, rickets is responsible also for a great deal of malnutrition found in children of this age group. Moreover, it is probable that the pneumonia and other respiratory diseases often attacking an alarming number of children under five in this district, are in part due to the low muscle tone and bad chest conditions following severe cases of rickets. "If these defects of early childhood and the illnesses which are likely to follow them are to be prevented, it is clear that something must be done to arrest the frightful incidence of rickets among the babies of this district," writes John C. Gebhart, director of the Department of Social Welfare of the Association for Improving the Condition of the Poor, in the *American Journal of Public Health.*

Fortunately both curative and prophylactic measures endorsed by the medical profession were available, and in 1923 the work was so organized that an intensive nursing followup for the majority of babies of this age group was provided. The work was carried on for four months and 150 cases were admitted and given careful attention. After study of records, the children were divided into three groups, according to amount of codliver oil consumed. The differences between those taking oil regularly and those who had taken it irregularly or in small quantities was so marked as to leave no doubt as to value of the oil in preventing rickets. It was impossible to trace any correlation between the feeding of the babies and the development of rickets, or to secure sufficient data to show the relation between time spent out of doors and the incidence of the disease.

The most significant contribution of the campaign was the demonstration that mothers can be induced by systematic home visiting to give codliver oil to their babies for the three winter months, and that at least seventy per cent. of such babies can be prevented from developing rickets in a district where this disorder is practically universal. The association feels also that a real beginning has been made in inducing mothers in this district to carry out prophylactic measures against rickets as a routine.

Obituary.

SELIAN NEUHOF, M.D.

Dr. Selian Neuhof, one of the country's leading cardiologists, died on October 6th, at his home in New York. He was sixty-three years of age at the time of his death. He was graduated in 1893 from the College of Physicians and Surgeons, where he specialized, as he did in his practice, on diseases of the heart. His two best known works, *The Heart,* and *Clinical Cardiology,* have been for many years standard textbooks in American medical colleges and schools. He was the writer of many articles on his specialty and related subjects and a frequent and valued contributor to the New York Medical Journal. Dr. Neuhof held many prominent positions in New York. He was formerly professor of medicine at Fordham University, visiting physician at the Central Neurological Hospital, consulting physician in cardiology at the Broad Street Hospital, and for many years associate attending physician and chief of the cardiac clinic at Lebanon Hospital. His loss will be deeply felt by the medical profession.

Dr. Neuhof is survived by his brother, Dr. Harold Neuhof, also a prominent physician and surgeon, and by his widow and two daughters.

WILLIAM HENRY B. AIKINS, M.D.

On Thursday, October 2, 1924, one of Canada's most widely known cancer specialists, Dr. William Henry B. Aikins, died from angina pectoris at his office, 134 Bloor Street, Toronto. Dr. Aikins was one of America's leading authorities on the treatment of cancer with radium. He was born in Peel County on August 22, 1859, and was graduated with the degree of M.B. from the University of Toronto, and with the degree of M.B.C.M. from Victoria University. After several years of postgraduate study in New York and various European cities, he took his licentiate in London in 1881 and the examination of the General Medical Council of the United Kingdom in 1883. Since that time he had practised in Ontario. He was active in many medical associations, eventually amalgamated into the Toronto Academy of Medicine, and was past president of this academy. He was one of the proprietors and editors of the *Canadian Practitioner,* and the author of many contributions to medical literature, particularly on his specialty. For a number of years he was a member of the consulting staff of Grace Hospital, and physician to the General Hospital. He acted also as consulting physician to the Toronto Hospital for Incurables and the King Edward Sanitarium.

Dr. Aikins had a wide acquaintance with medical men in Europe, and attended officially and as an individual many of the European conferences on medical subjects. He was one of the organizers of the American Radium Society, and one of its first presidents. He was also a member of the Ontario Medical Association, the Canadian Medical Association, and the British Medical Association, and a Fellow of the American College of Physicians. He was a member of the York Club, the Royal Canadian Yacht Club, and the Æsculapian Club. His death is a great loss to the profession as a whole.

News Items.

Nobel Prize Award.—The 1924 Nobel prize for medicine has been awarded to Professor Willem Einthoven, professor of physiology of Leyden University.

Dietetic Convention.—The American Dietetic Association held its seventh annual convention at Swampscott, Massachusetts, October 13th to 16th.

Dental Exhibit.—The Allied Dental Council will have a mouth hygiene and health exhibit in the Astor Library building of New York, from November 10th to December 5th.

Civil Service Examination.—Applications for medical officers, Junior, Grade A, and Grade B, at entrance salaries of from $1,680 to $3,000 a year, will be received until December 30, 1924, by the U. S. Civil Service Commission.

Public Lectures at New York Academy.—Seven lectures on health education and the prevention of disease, open to the public, will be given by the Medical Society of the County of New York, in cooperation with the Academy of Medicine, from October 29th to December 10th, at the Academy building.

Police and Fire Surgeons' Association.—At the recent meeting of the Police and Fire Surgeons' and Medical Directors of Civil Service Commission, held in New York, Dr. Harry M. Archer, honorary surgeon of the New York Fire Department, was elected president, Dr. J. J. Wyeth, secretary, and Dr. F. M. Banta, treasurer.

Harvey Society Lectures.—Dr. William Snow Miller, professor of anatomy, University of Wisconsin, delivered the second Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, October 25, 1924. His subject was "A Study of the Normal and Pathological Histology of the Lung."

Professor A. V. Hill, E.R.S., professor of physiology, University College of London, will deliver the third Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, November 5, 1924. His subject will be "The recovery process after muscular exercise in man."

New Clinic.—The new Hospital for Deformities, New York, has received through the generosity of a friend a donation of $5,000 for the establishment of a complete bronchoscopic clinic for direct laryngoscopy, bronchoscopy and esophagoscopy. The clinic will be under the direction of Dr. M. Joseph Mandelbaum. Announcement of the opening of this department for the reception of patients will be made later.

Alvarenga Prize.—The College of Physicians of Philadelphia announces that the Alvarenga prize for 1924 has been awarded to Dr. Gordon Cameron, Victoria, Australia, for his essay entitled "Pancreatic Anomalies; Their Morphology, Pathology, and Clinical History." Essays for the 1925 contest must be received by May 1st, and may be written on any medical subject. Details may be learned from Dr. John H. Girvin, of 19 South Twenty-second Street, Philadelphia.

Five O'Clock Lectures at the Postgraduate.—November lectures have been announced as follows by the Postgraduate Medical School and Hospital, to be given Wednesday afternoons at five o'clock. All practitioners of medicine are invited. November 5th: Dr. Harbeck Halsted, "The Toxemias of Pregnancy"; November 12th: Dr. Fred H. Albee, "Rehabilitation Surgery"; November 19th: Dr. Linnaeus E. LaFetra, "Meningitis—Diagnosis and Treatment"; November 26th: Dr. Ludwig Kast, "The Treatment of Colitis."

Personal.—Dr. Shepherd Ivory Franz, of St. Elizabeth's Hospital, Washington, D. C., and the George Washington University School of Medicine, has resigned and is to become a member of the department of psychology of the University of California.

Dr. David Felberbaum, of New York, has removed his offices to 320 West Eighty-ninth Street.

Dr. Benjamin Schwartz, of New York, has been appointed visiting physician at St. Mark's Hospital.

Dr. E. C. Levy has retired as director of public welfare of Richmond, Virginia, to be succeeded by Dr. W. Brownley Foster.

Dr. Laura Ida McLaughlin, formerly research worker at the University of Chicago, has joined the staff of the Bureau of Home Economics of the U. S. Department of Agriculture.

Medicinal Use of Alcohol.—The city council of DeKalb, Illinois, has enacted an ordinance prohibiting the filling of prescriptions of medicinal liquor unless the mixture is so compounded as not to produce intoxication; intoxicating liquor must be furnished directly by the physician to the patient under his care. The physicians of the city have appealed to the state association for assistance in securing repeal of the ordinance.

American College of Surgeons.—At the recent clinical congress of the American College of Surgeons, held in New York, the following officers were elected, to be installed at the 1925 congress: President, Dr. Rudolph Matas of New Orleans; first vice-president, Dr. Eugene Hillhouse Pool; second vice-president, Dr. John Sinclair McEachern, Calgary, Alberta.

The following were elected to the Board of Regents, their terms expiring in 1927:

Dr. George W. Crile, Cleveland; Dr. Robert B. Greenough, Boston; Dr. Allen B. Kanavel, Chicago; Dr. John G. Clark, Philadelphia, and Dr. George Henry Murphy, Halifax, N. S.

Hospital Administration Conferences. — The New York Postgraduate Medical School and Hospital is holding a series of conferences on hospital administration, open to all who are interested. The November 7th meeting will be on "Necessity for closer Cooperation Between Architects, Hospital Boards and the Nursing Profession in Relation to the Construction of Hospitals for the Purpose of Facilitating Nursing Service," led by Alice Shepard Gilman, R. N. The November 14th meeting will cover "Establishing and Maintaining Proper Relations Between Hospitals and Medical Schools," an address by Dr. Charles H. Young. The last meeting, on "Higher Education in the Nursing Profession," will be led by Annie W. Goodrich, R. N.

Research and Scholarship Funds.—Funds for a research fellowship in preventive medicine for two years have been provided for the University of Chicago by an anonymous donor.

Five scholarships at the University of Maryland, medical department, have been provided in the will of the late Dr. Clarence Warfield. A scholarship in this department has also been provided for by a gift from Miss Eleanor S. Cohen.

A legacy from the late William F. Milton, yielding an income of about $50,000, has been received by Harvard University. If not desired for a library building, the fund may be used for special investigations, including medical subjects.

The University of Colorado has received the sum of $5,000 and is assured an income of $1,000 a year, for the purchase of books on medical research, by the generosity of Mrs. Charles Denison, of Denver.

Columbia University announces a donation of $15,000 from the Borden Company for research in food chemistry and nutrition and $6,000 from an anonymous donor for the surgical research laboratory.

Resolutions.—The following resolution was adopted by the Yorkville Medical Society on the death of Dr. Selian Neuhof:

WHEREAS, Our late colleague, ex-president and friend, Dr. Selian Neuhof, who has departed from our midst, and

WHEREAS, During his entire professional career devoted himself intensely to scientific research and contributed materially to the advancement of medical science, and

WHEREAS, He has given his valuable time and services unstintingly to the development, growth and scientific advancement of the Yorkville Medical Society, and

WHEREAS, In the course of the manifold activities on behalf of the Yorkville Medical Society, he also officiated as the presiding officer with marked distinction and great tact, Therefore be it

Resolved, That the Yorkville Medical Society deeply mourns its regrettable loss, and be it resolved that these sentiments be expressed upon the minutes of the Yorkville Medical Society, that they be published in the medical journals and a copy thereof be sent to his family.

A. KAHN, M.D., *President.*
I. GLASSMAN, M.D., *Secretary.*

At a special meeting of the Board of Surgeons of the New York Eye and Ear Infirmary, held on October 24, 1924, the following resolution was unanimously adopted on the death of Dr. Charles E. Perkins:

Resolved, That the Board of Surgeons of the New York Eye and Ear Infirmary records with profound sorrow the death of its late colleague, Dr. Charles E. Perkins, who has faithfully served the Infirmary for the past eighteen years. The Board of Surgeons extends to the bereaved widow and family its sincerest sympathy.

E. B. DENCH, M.D., *Chairman.*
ROBT. LEWIS, M.D., *Secretary.*

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

London, *September 24, 1924.*

HEALTH IN ENGLAND AND WALES

Sir George Newman, chief medical adviser to the Ministry of Health, has just issued a masterly memorandum on the national health. Of course it is a truism to state that sanitary science has practically extinguished some diseases and greatly checked the ravages of others, until the death rate of England and Wales is the lowest recorded. With regard to the preventive treatment of the individual, education is needed and reforms of a drastic nature required. For example, thousands of women die annually in childbirth for lack of proper care and precautions. Much of this maternal mortality and sickness could be prevented, yet only a small proportion of the seven hundred thousand mothers who give birth to children every year submit themselves to antenatal supervision. The death rate of infants, although lower by far than formerly, is still too high. Since the establishment of schools for mothers, of maternity and infant welfare centres, and of other educational agencies for assisting mothers in their maternal duty, the infant mortality rate in England and Wales has fallen by fifty per cent.

One of the great causes of sickness, perhaps, on the whole, the greatest in England and Wales, as in other countries, is digestive disturbances, frequently due to errors of diet. Knowledge of food values and the needs of the body is lacking, with the result that much money is spent on unsuitable food, while many valuable and cheap foods are entirely neglected. Only by teaching individuals what, when and how to cook and eat can this be overcome. Meals should be regular and restful occasions.

Disease of the respiratory tract is one of the commonest causes of sickness in England and Wales, and diseases in this group are one of the chief causes of death. Neglect of the common cold and behaviour which insures its direct transmission to others, are widespread and habitual. People suffering from colds breathe, sneeze, and cough in other people's faces, careless or ignorant of the fact that they are highly infectious.

The commoner infectious diseases, such as measles, diphtheria, scarlet fever, smallpox, whooping cough, tuberculosis, and venereal disease, bring about a devastating amount of disability and death. These are spread almost entirely by contact with infectious persons. People must be taught that diphtheria germs do not live in drains, but in throats, and may be conveyed to others by the sick, by contact. They must be taught that it may be dangerous deliberately to allow young children to become infected with measles, whooping cough, or scarlet fever, that relatively minor diseases may prove mortal if not adequately treated and properly nursed; that tuberculosis is not necessarily hereditary, and therefore predestined, but is the result of personal infection or drinking tuberculous milk.

It is pointed out that it is usual to attribute the present day prevalence of nervous and mental troubles to the rush and worry of modern life. Psychologists tell us, however, that although urban conditions may be contributory causes, the predisposition to the trouble may arise quite early in life, often in infancy.

THE DANGERS OF DYED FURS

A report by Dr. Allan C. Parsons on the results of an inquiry concerning cases of dermatitis caused by the wearing of fur collared garments has been issued recently by the Ministry of Health. The subject attracted attention first in the winter of 1922-23, when cases were reported frequently in London and throughout the country generally. Though the malady in question is not in most cases of serious import, the symptoms in some cases were severe, and in any event the rash is disfiguring and uncomfortable. The furs concerned were of a cheap variety made from rabbit skins dyed to resemble coney and known as "beaver coney." They are used as cheap ornamental additions to coats and mantles, and take the form of collars and cuffs. According to the Fur Trade Association these furs are exclusively produced and dyed in foreign countries, notably in Belgium, France, Germany, and the United States. Aniline dyes are used in the preparation of the furs, and examination of specimens proved that the skin troubles are due in particular to the employment of paraphenylenediamine and metaphenylenediamene. It is necessary with both these dyes to employ an oxidizing agent, such as peroxide of hydrogen, and if oxidation is complete the dyed article is innocuous. In many of the furs under suspicion, however, the oxidation process has not been completed but arrested, at a stage where actively irritant bodies are produced. The conclusion arrived at therefore is that defective or careless technic in the use of potentially dangerous dyes is, in all probability, the cause of fur dermatitis, and the hope is expressed that effective measures will be taken by the trade to remedy these conditions.

COTTON SPINNERS' CANCER

Recently several cases of cotton spinners' cancer have been reported. Notably a case of epithelioma of the scrotum from which a spinner had died, an account of which was given in the *Lancet*, August 16th last. This was a test case a county court decision having been given that the disease was excited by reason of the nature of his employment and therefore fell within the scope of industrial diseases under the Workmen's Compensation Act. The Operative Cotton Spinners' Amalgamation have decided to accept the decision. According to the operatives' secretary, there are one hundred cases of cancer on his books awaiting decision. Owing to the publicity which has been given the case much is hoped for in the direction of prevention of the disease. The council of the Amalgamated Association of Operative Cotton Spinners and Twiners express the opinion that no worthier field in which to work can be found than for medical scientific men by investigation to attempt to banish this disease from all connection with cotton spinning. It is further suggested that the trade itself in conjunction with the medical profession, might investigate the cancer producing properties of mineral oil and direct their efforts to the production of an oil innocent of such properties, or, at least, to the provision of improvement of preventive measures.

NEW BOOK

An extraordinarily original book has been written by Mr. J. E. R. McDonagh, F.R.C.S., surgeon, London Lock Hospitals, late Hunterian Professor, Royal College of Surgeons of England, and published by William Heinemann (Medical Books), London. This work, termed the *Nature of Disease,* simply teems with original views and moreover, proofs in support of these views are brought forward in large numbers.

It is a book calculated in a very high degree to stimulate the imagination, as its main theme is the revolutionary argument that all diseases proceed from one cause, the loss of the electrons from the protective particles of the blood, that is, a successful attempt on the part of the invading organism to extract from the protective particles of the blood their free electricity. Recovery is the reversal of this process, the recapture from the invading organism of this electricity.

LETTER FROM VIENNA

(From our own correspondent)

VIENNA, *August 20, 1924.*

EFFECTS OF PROLONGED TOBACCO SMOKING

At a recent meeting of the medical society, Dr. Wisselbach read a paper on the effects of prolonged tobacco smoking. He stated that tobacco smoke contained nicotianin, collidine and other pyridine derivatives, such as acids, resins, carbon dioxide, hydrocyanic acid and ammoniacal salts, as well as the nicotine. Two drops of nicotine placed on a dog's tongue produced great weakness, convulsions, and death in less than a minute. Eight drops were sufficient to kill a horse. Tobacco contained from two to eight per cent. nicotine, and M. le Bon, a French investigator, has determined that although this was changed in smoking, still it was converted in other pyridine products, which were just as poisonous. Dr. Wisselbach found that the bodies did not condense to any appreciable extent in the mouth, and were for the most part exhaled so that the physiological effect of ordinary smoking was nil. Susceptible persons, however, might be affected by breathing the air in which there was much tobacco smoke.

The action of nicotine has been shown by the investigations of Petit to be intermediate between that of the bromides and digitalis. It soothes the nerve system, but causes a powerful and rapid contraction of the vessels and a rise in blood pressure. One of its best known dangers is angina pectoris, caused perhaps by the severe contractions of the coronary arteries. Prolonged use induces the development of arteriosclerosis. Tobacco is a habit drug like opium, cocaine and alcohol; its devotees, although aware of its harm, lose the force of will necessary to break the habit. Tobacco smoke has apparently no bactericidal action on any microorganisms present in the lungs. One of the first effects of an overdose is nausea. Prolonged smoking has been proved to be a distinct factor in the production of digestive troubles.

INCREASE OF LENGTH OF LIFE OF ROUMANIAN WOMEN

The detailed statistical results of the last census, published at the end of last month, have been discussed by various medical men from different points of view. A noted gynecologist has examined the data available for comparing the duration of life of men and women, and concludes that women live longer than men. The average lifetime of the Roumanian women, according to the census taken in 1910, was 42.8 years, but according to the last census it is now fifty-one years. In some parts of Roumania the improvement is still greater. For instance, in the Székely district in Transylvania the average is 56.6 years. According to this gynecologist the longevity of women is due to the fact that women work less than men, and are less liable to industrial and other accidents. The data of the last census show that there are fewer hysterical and nervous women than in other countries. Insanity has also decreased slightly. These favorable results are for the most part due to the general improvement of the standards of life in recent years. Wages in Roumania have been increased considerably during the latter years in agriculture, trade and manufacturing.

NEARSIGHTEDNESS OF VIENNA SCHOOL CHILDREN

Dr. Wiljeim, in his account of the examination of two hundred textbooks from a sanitary point of view, draws particular attention to the fact, already established by many prominent investigators, that nearsightedness in children either originates or develops in connection with the schoolroom. The chief cause is the too prolonged reading, writing and drawing in which visual accommodation, as well as convergence, is greatly fatigued. Undue strain of the muscles of accommodation causes an active hyperemia; the venous circulation is hindered, there is an increase in the intraocular pressure and the sclerotic is gradually stretched. Too strong convergence works even greater harm. It is, of course, understood that in some children nearsightedness is hereditary, and as a result, they become affected more quickly than their healthier comrades. In addition, nearsightedness may be the result of insufficient light and improper equipment on desks and other school furniture.

Dr. Wiljeim insists that the paper used in the textbooks should not have a glossy surface. Under artificial light a glossy surface causes improper focusing of the eye and necessitates frequent changes in the position of the book as well as of the head. The paper should be thick enough to prevent the printing on one page penetrating to another. A few authorities have recommended yellow paper, but the majority favor white paper, which gives a better contrast between the printed matter and the background.

DIABETES AND PREGNANCY

Dr. Elischer, of Budapest, says that if diabetes occurs in a woman of child bearing age, it usually suppresses menstruation and often produces atrophy of the uterus. In some cases, however, menstruation continues; such patients may become pregnant. Since diabetes in young subjects is of a more severe

type, those diabetic women who are still capable of becoming pregnant exhibit a dangerous form of this disease. Pregnancy aggravates it and hastens its progress. If diabetes becomes associated with pregnancy, viz., if a pregnant woman becomes diabetic, the prognosis is more favorable, because the diabetes usually subsides after confinement. The effects of diabetes upon pregnancy and the puerperium are extremely deleterious. In about two thirds of the cases intrauterine death of the child was observed. Hydramnios is a frequent complication. During the lyingin death may supervene in the same manner as after operation, with the symptoms of coma and collapse. The obstetrical management of diabetes with pregnancy is a difficult problem. Dr. Elischer believes that the termination of pregnancy, and that, too, at the earliest possible date, is the only course which can logically be followed.

SODIUM SULPHITE A DANGEROUS FOOD PRESERVATIVE

A series of experiments to determine the effects of the habitual use of sodium sulphite in the food were performed in dogs and other animals in the Vienna physiological laboratory of the university. The results, although not quite new, are valuable from the viewpoint of public hygiene, considering the large amount of this substance used as a food preservative Ten dogs were under observation, two being controls and receiving the same weight of untreated meat, as was done several years ago by Dr. Harrington in the United States. These dogs were fed upon freshly hashed beef, to which was added fifteen to twenty per cent. of pure crystallized sodium sulphite. From the start all ten animals gained in weight, but about the seventh week all except the control dogs begun to lose. At no time did any of the animals show any outward evidence of poisoning up to three months, when some slight manifestations of poisoning appeared. In the fifth month all animals were killed. On section the macroscopic appearances were negative in all respects, but microscopical examination showed a parenchymatous degeneration of the kidneys. Each showed marked fatty degeneration of the renal epithelium, and in one case there was an acute interstitial hepatitis in addition to and probably dependent upon parenchymatous changes. The control dogs showed no changes whatever. The conclusion is drawn that at least for dogs, and probably for human subjects too, sodium sulphite is a dangerous admixture to food.

LATIN AMERICA LETTER

(*From our own correspondent*)

Balboa Heights, *September 15, 1924.*

QUARANTINE AGAINST SALVADOR ON ACCOUNT YELLOW FEVER

Surgeon C. P. Knight, Chief Quarantine Officer of the Panama Canal, has recently issued an embargo on all nonimmune passengers and members of the crew of ships arriving at the Canal ports which have touched the ports of Salvador. This quarantine is the result of yellow fever at San Salvador. The order includes all passengers not immune to yellow fever from all Salvadorian ports and also from the port of Amapala, Honduras, which lies just across the Bay from La Union, Salvador. All such passengers arriving at the Canal will be placed in quarantine for the period totaling six days from ports of departure. Certification by ship's surgeons giving daily temperature readings of passengers who have embarked from the above mentioned ports will be required. Steamship companies have been advised to allow no landing of transit passengers in the ports of Salvador.

The prevalence of yellow fever in San Salvador, while not alarming, is of such an extent that every precaution must be used to protect the Canal Zone. Some weeks ago Dr. Knight made an investigation of conditions in Salvador and in his report to the Governor of the Canal strongly recommended that further intensive studies be made in order to determine the foci of infection. At present Dr. Henry Hansen of the International Health Board is at San Salvador studying the outbreak. Frequent reports are received from him relative to current conditions. To date there has been reported forty-one cases with five deaths. This is the first outbreak in Central America for a number of years.

PANAMA'S NEW HOSPITAL DEDICATED

Panama's new $3,000,000 hospital known as the Santo Tomas Hospital was recently dedicated by Dr. Belisario Porras, President of the Republic of Panama. About four thousand persons attended the ceremony, who massed around the main entrance in an endeavor to listen to the speeches delivered by the President and other notables of Panama. Bronze medals commemorative of the occasion and descriptive booklets were distributed among the guests. The medals bore the bust of the President while on the reverse side a general view of the hospital which today is the most beautiful structure in Panama and perhaps the most costly in the entire Republic. Immediately after the ceremony the new hospital was thrown open to the public for inspection. A reception took place upon the second floor of the main building.

The old hospital was evacuated recently, all the patients and staff being transferred to the new hospital. The old Santo Tomas which was a landmark of the city of Panama for many years is now a thing of the past. The new hospital is pleasantly situated in the Exposition Grounds and overlooks the Grand Gulf of Panama. The buildings are imposing, being constructed of cement with stucco finish and are entirely fireproof. In front of the hospital in the spacious grounds is the statue of Bolivar.

CANAL ZONE HEALTH DEPARTMENT INCREASES FUNCTIONS

Col. W. P. Chamberlain, Chief Health Officer of the Canal Zone, announced recently the inauguration of increased activities in the Health Department especially in reference to child hygiene. While there has always been close contact between the health department and the public schools in supervising the health of the school children, nothing on an extensive scale has heretofore been attempted. Dr. C. P. Knight, Chief Quarantine Officer, who previous to coming to the Canal Zone was engaged in organizing divisions of child welfare in some of the

Western States, will assume the task of organizing the new activities in the health department of the Canal Zone.

Dr. W. P. Cox of Ancon Hospital has for the past year been conducting health centres in different parts of the Zone for the benefit of mothers, infants and children of preschool age. This has been mostly volunteer work but has been helpful to employees' families. The results expected from the increased activities are: Further reduction in the death rate among expectant mothers and infants; raising the standard of health among children of the preschool and school age groups; control of communicable disease through routine inspection, thereby improving the daily average attendance. Miss Katherine Luby, an experienced public health nurse who has specialized in child hygiene for the past six years in the States, has just arrived on the Isthmus and has been assigned to these activities.

IMPROVEMENT MADE IN GARBAGE DISPOSAL

A vast improvement in garbage disposal of the Canal Zone and Panama has recently been made which has proved both a great saving in economical administration and further reduction in fly breeding. The Zone and Panama use the burial system in disposal. Heretofore quantities of larvacide composed of a resin soap emulsion of crude carbolic acid was sprayed on the top of the burial ground as a fly larvæ exterminator. The cost of this in material alone amounted to $100 a month. Experiments have shown that ordinary crude oil does the work more efficiently and at a saving of $80 a month in material. It is also shown that the oil is a much more efficient larvacide. Since the adoption of this method fly breeding has been practically stopped both at the garbage dump and also the manure dump. It is extremely rare to see a fly in any house in the Canal Zone, due to the efficient methods of garbage and manure disposal.

NOTED SCIENTIST ARRIVES ON ISTHMUS

Dr. W. J. Berg, professor of entomology of the University of Arkansas has recently arrived at the Canal Zone, where he will proceed to Barro Colorado Island, the Government Experimental Research Station, for the purpose of an extensive study of the effects of venom stings on the human body of such insects as the tarantula, scorpion, centipede and numerous other alleged poisonous creatures. Professor Baerg is going to allow these insects of the tropics to sting him and scientifically note the physiological reactions upon his own body. He has performed similar experiments in the States with such insects and does not believe that the tropical varieties are any more poisonous than those of the States. Dr. Baerg stated that "There is a small black spider with red markings found in all tropical and temperate regions which is poisonous. There is no evidence in scientific literature that the tarantula or centipede of the tropics is poisonous."

ISTHMIAN CANAL ZONE MEDICAL ASSOCIATION MEETING

During the month of August a special meeting of the Isthmian Canal Zone Medical Association was held at the Century Club in Panama in honor of the distinguished men who visited the Canal following the conference on tropical medicine at Kingston, Jamaica. Practically all the physicians of the Canal Zone and of Colon and Panama attended this meeting and had the pleasure of listening to many addresses by the noted group of medical men.

The following noted medical men were on the program: Dr. F. G. Banting, of Toronto, Sir Arthur Newholsme, of London, Dr. Arthur Patterson of Kenya, East Africa, Assistant Surgeon General Henry R. Carter, U. S. Public Health Service, Professor M. J. Roseneau of Harvard.

CHANGES IN MEDICAL STAFF OF CANAL ZONE

The following changes are made in the Medical Force of the Canal Zone Health Department: Dr. Iril C. Bedwell resigned, effective September 30, 1924. Dr. Otto C. Kostall resigned, effective September 30, 1924. Major William A. Murphy, leave of absence for two months, October 1, 1924. Captain Julius Newgard, accompanying Boy Scouts on their annual encampment to Chiriqui, Panama.

NEW CHIEF HEALTH OFFICER FOR CANAL ZONE

Assigned by the Surgeon General of the Army and appointed by the Governor of the Canal Zone, Col. Weston P. Chamberlain, M. C. U. S. A., arrived at the Canal Zone on the transport St. Mihiel, June 18, 1924, to assume the duties of chief health officer. Previously to his assignment to the Canal Zone, Colonel Chamberlain was on duty in Washington, D. C., as Commandant of the Army Medical School. He relieves Col. Henry C. Fisher, who has been chief health officer for the past five years, while Colonel Fisher is being assigned to the post just vacated by Colonel Chamberlain. Throughout the efficient administration of the former chief health officer, great economy in matters of sanitation and mosquito control has been effected. Officials and employees of the Canal greatly regret the departure of Colonel Fisher, whose kindly demeanor toward all has been appreciated.

YELLOW FEVER EXPERT LEAVES FOR THE STATES

Dr. Henry Hanson of the International Health Board arrived in Panama on June 7th en route to the United States. Dr. Hanson is the director of the campaign against yellow fever in the Republic of Colombia. His mission to the States is a sad one as he is accompanying the body of his wife, who died here six months ago. Dr. Hanson reports that the control of yellow fever with its attending mosquito eradication is progressing satisfactorily. In his latest report he recommends a policy of watchful waiting. His specific recommendations to the International Health Board are:

1. A series of surveys should be made in the largest and most important towns, making a stegomyia index;
2. Vital statistics should be thoroughly examined for any recent undue number of deaths from fevers, Bright's Disease or infectious jaundice;
3. Venezuela should be visited, especially the Maracaibo basin. This appears to be the only likely source of reinfection for Columbia;
4. It appears desirable that the work done in Venezuela should be under the same general direction as that in Colombia as the two countries form practically one and the same focus.

The length of time for the continuation of the work in Colombia depends more upon the conditions in adjacent countries than it does upon Colombia.

By the end of the year 1924, Colombia could safely be left to itself, provided that there is no menace from neighboring countries.

Beside the campaign in yellow fever, Dr. Hanson has been making exhaustive studies in relapsing fever. He brought with him specimens of ticks for experimental study. These studies are now being conducted at the Ancon Hospital laboratory by the entomologist of Dr. Hanson's staff, to determine the natural infectivity of ticks in relapsing fever. Results of these investigations should have an important bearing on the future control of the disease.

MEDICAL STAFF ADDITIONS AND TRANSFERS

During the past month Major T. J. Leary, M. C. U. S. A., has been relieved as superintendent of the Colon Hospital and assigned to duty in the United States. Major Thomas S. Mebane has been appointed superintendent in his place, effective June 23, 1924. The following officers of the Medical Corps of the Army have recently been assigned to duty with the Health Department: Capt. Paul G. Capps, Capt. Thomas H. Steward and Capt. William W. Conger. These officers are expected on the next transport to reach the Canal. Dr. Otto A. Kestal has been appointed physician with the Health Department. Dr. Kestal has just completed one year's satisfactory internship in the Ancon Hospital.

PERU PASSES RESOLUTIONS AFFECTING QUARANTINE PROCEDURE

As a direct result of the Conference of Maritime Quarantine Authorities of the West Coast of South America held last February in Panama, the Peruvian Government has passed the following resolution:

Whereas: The Panama Canal with its terminal ports of Colon and Balboa are under one sanitary jurisdiction; and

Whereas: The recent Panama Sanitary Conference asked by special vote that the sanitary unity of the Canal be recognized; therefore be it

Resolved: That vessels stopping at Colon and Balboa will only need one bill of health for their being admitted in Peruvian ports.

Be it registered, communicated and published.

Seal of the President of the Republic. Medina.

Peru has the honor of being the first country to modify regulations governing quarantine as a result of the above mentioned conference. As an economic measure, this modification is of particular interest to the shipping interests.

YELLOW FEVER IN SALVADOR

It is reported that one death and several cases of supposed yellow fever have occurred in Salvador during the past week. Because of the reputed existence of this disease, and as a precautionary measure to the Canal Zone, the Governor has ordered Dr. C. P. Knight, chief quarantine officer, to proceed to Salvador for consultation with the Salvador authorities relative to the situation. If the existence of yellow fever is proved, it will be the first appearance of the dread disease for a long period. Active campaigns have practically wiped it out of Central American countries and the greater part of South America. The last case of yellow fever appeared in Panama in 1905, in Ecuador in 1919, in Mexico and Colombia, 1923. In the event that yellow fever is discovered, the Canal Zone will necessarily quarantine against ports in Salvador.

STUDIES IN MOSQUITO CONTROL

A recent paper by Dr. D. P. Curry, assistant chief health officer of the Panama Canal, describes the mosquitos of the Canal Zone, especially the Anopheles, and their control. He demonstrated that by field identification of the larvæ, using a portable microscope, a sanitary inspector is enabled rapidly to determine the breeding places of dangerous or annoying species of mosquitos, to locate the source of flights into neighboring settlements, and to direct with precision and economy efforts at their control. Of the eighteen genera and 135 species identified here, but few have proved dangerous or especially annoying. Of the ten species of Anopheles, but two, A. Albimanus, and A. Albimanus variety Tarsimaculata, are believed to be of great economic importance in transmitting malaria, and control work, especially over distances greater than half a mile from protected centres, should be directed chiefly against them. Recent studies seem to indicate that on the Atlantic side of the Isthmus, flights of this species are invading the terminal cities over a distance of three miles or more, much of it over the open water of Limon Bay.

Letters to the Editor.

BLOOD SEDIMENTATION

Detroit, *September 6, 1924.*

To the Editor:

Dr. M. E. Alexander's article on "Clinical and Experimental Observations on Blood Sedimentation," appearing in the June 4th number of your Journal, was called to my attention recently. Having been associated with Dr. Bernhard Friedlaender in the preparation of his article on the subject in the *American Journal of Obstetrics and Gynecology*, Vol. VII, No. 2, February, 1924, I was very much interested in Dr. Alexander's work.

I should like Dr. Alexander to compare his work with ours. I note that he considers a sedimentation time of one hour normal. You will see that we have established from the study of a large number of cases that 1,000 to 1,200 minutes is the normal time. We consider a sedimentation time of less than three hours distinctly pathological.

In pregnancy the sedimentation time varies very definitely according to the length of gestation as is shown clearly in Friedlaender's article, and not "averaging twenty minutes," as Alexander states.

I am very pleased, however, to note that the work on sedimentation time is being appreciated elsewhere in this country.

Emil D. Rothmann, M.D.

ITALIAN EMIGRATION SERVICE

New York, *September 19, 1924.*

To the Editor:

According to a correspondence from Washington, published in the issue of your paper of May 7, 1924, it would seem that it is only lately that Italy has established homes for emigrants at Naples, Genoa, Trieste, and Bardonecchia for the purpose of selecting and cleansing the emigrant before sailing. This presumed awakening in the field of emigration is

also supposed to be the outgrowth in Italy of a system installed in the last four years in Europe by Dr. Hugh S. Cumming, Surgeon General of the United States Public Health Service.

Now, with all due regard for the excellent work done by Dr. Cumming, it seems to me that the above statement should be modified. The Italian Government, through the general bureau of emigration, organized in 1901 a complete service of sanitary inspection, aid, and selection of emigrants, and since 1902 has detailed a physician as Royal Commissioner to every transatlantic steamer, to look after the welfare and hygiene of the emigrants during their voyage. And since 1910 a medical officer of the Royal Navy has been permanently stationed in New York to act in cooperation with Ellis Island in all questions relating to immigrants from Italy.

It was also in 1910 that in the port of Naples was established a special home with all conveniences for bathing and cleansing and for a complete sanitary supervision and selection of emigrants. After the war a similar institution was opened in Trieste. The only home that can be considered new is the one of Bardonecchia, near the borders of France, opened only last year on account of the increased Italian emigration into France.

It is not that only lately the Italian Emigration Service has been organized, but rather that only recently competent American authorities have interested themselves in this matter and gone to inspect it. And it is to the credit of Italy, that all these inspections have resulted in warm commendation of the work done by the Italian Emigration Bureau.

CARLO SAVINI, M.D.

THE TITLE OF DOCTOR

NEW YORK, *September 14, 1924.*

To the Editor:

A whole line of citizens have taken upon themselves the care of the health of the individual and the family, and have appropriated the title of "doctor." Types of "doctors" have multiplied beyond the telling. Selfstyled "doctors of chiropody"; "doctors of chiropractic"; "doctors" of health; even "doctors" of laboratory health; not to speak of the "doctors" of the seventy cults recently listed by one health board. The populace at large enjoys these cults and faddists, and attends their sessions, calls upon them for services requiring some knowledge of the human mechanisms. As long as the socalled doctor does not actually use the knife or prescribe through ordinary druggists, he is safe and within his rights as a citizen who has assumed as his patriotic duty the care of the health of the individual and his family. Let diphtheria rage through the community; let the enlarged breast be rich in cancer and not in fat; let the malalignment of the vertebræ be tuberculous, what matters—The drugless healers must go on!

At whose threshold should all this be laid? Very recently in our State, an attempt was made to register physicians annually (at a fee, of course) and then to have the machinery set up to investigate unlicensed and illegal practitioners. It was not possible to get the doctors to agree on the utility of this legislation. It seemed that it was penalizing the innocent to reach into the maelstrom of the guilty. The physician is already burdened by fees and taxes. He pays for his medical student certificate with which he enters medical school. He pays for the privilege of taking and passing the examinations licensing him to practise medicine and surgery; he pays to register in the county in which he practises; he pays for the privilege of prescribing narcotics to patients in pain (for a while he paid both a State and Federal tax). The physician is permitted to prescribe alcohol, and to purchase it for office use, although how and why no fee was attached to this nuisance is not understood. So perhaps it is no wonder that it was not possible to get physicians to agree on giving themselves another tax, another set of papers to fill out annually, and another number to add to the growing list each of us has.

It occurred to me that honest doctors can change many things without more laws and more numbers. Suppose we agree that instead of a door plate or window sign which reads, Doctor Jones or as some will have it, J. Jones, M.D., we have our signs read:

John Johns, M.D.
Licensed to Practise Medicine and
Surgery in This State.

If all who may honestly do so, take this means of informing the world at large that the provisions of the State law of their community have been satisfied, it will put the outcast where he deserves to be—beyond the pale. The objections to making public one's privilege legally to carry on the profession of physician and surgeon cannot be strong. No physician objects to having his narcotic license number printed on his prescription blank. No physician can object to having his license and county certificate in his office consulting room. Putting oneself on record makes the illegal practitioner either quit or perjure himself!

The protection once afforded by the title of doctor to the health seeker has become a spider web. Let us take the matter up; let us be honest; even if it entails a larger placard over our door bell, or two lines instead of one on our letter head.

HERMAN GOODMAN, M.D.

ALCOHOL AND CARBOLIC ACID

VANCOUVER, CANADA, *October 10, 1924.*

To the Editor:

Dr. Tweddell's letter regarding carbolic acid as an antidote for alcoholic poisoning (MEDICAL JOURNAL AND RECORD, October 1st, page 353) reminds me of an incident. I was searching for a satisfactory antiseptic to use in gastric lavage, and among other things I tried ten drops of a mixture of equal parts of alcohol and carbolic acid, dissolved in two quarts of hot water. The patient did not faint but respiration ceased, the muscles relaxed completely and she became unconscious. Her chair was tipped immediately to lower her head, and in a minute or two she had recovered. Next day the same dose was used on a strong man, with a similar result. Since then I have carefully avoided using alcohol as an antidote for carbolic acid internally. Glycerine is just as efficient, and no bad results follow. If a patient has just swallowed alcohol I would not give carbolic acid. After the alcohol has been absorbed it may be safe to do so.

T. PROCTOR HALL, M. D.

Book Reviews

SKIN DISEASES

Handbook of Skin Diseases. By Frederick Gardiner, M.D., B. Sc. (Public Health), F.R.S.C.E., F.R.S.E. Second Edition. New York: William Wood & Co.; Edinburgh: E. S. Livingstone, 1924.

In the second edition of his handbook on skin diseases, the author has written a creditable and certainly readable little volume. The purpose of the book is avowedly to present the diagnosis and treatment of the more common diseases of the skin. Some of the less common diseases are also included and their descriptions have necessarily been rather meagre and unsatisfactory.

There is a good deal of up to date information and sound common sense, interspersed with frequent references to personal experiences, some of them derived from service in the recent war. In his attempt to be up to date the author follows the questionable practice of dropping the word eczema and using the word dermatitis in its place. On the other hand in discussing pompholyx (dyshidrosis) at some length he fails to mention the fact, which is generally recognized, that many cases, if not a majority, are simply examples of ringworm infection. Like many European writers the author seems wedded to the use of ichthyol, a drug whose vaunted usefulness has of late been seriously questioned.

The writer's experience with tuberculosis of the skin, so much more common in Europe than America, has helped him to write an excellent chapter on this perplexing subject.

The book is of octavo size, containing 246 pages. There are forty-six black and white illustrations of rather mediocre value, and twelve excellent colored plates made from wax models. The paper, printing and general appearance of the book are all that could be desired.

X RAY MANUAL

Manual of Practical X Ray Work. By John Muir, B. Sc., M.B., Ch.B., in collaboration with Sir Archibald Reid, K.B.E., C.M.G., L.R.C.P., and F. J. Barlow, B. Sc., F. Inst. P., A.R.C.Sc. With 456 Illustrations. Being a third edition of the manual by Arthur and Muir. New York: Paul F. Hoeber, Inc., 1924. Pp. 524.

It is a pleasure to give unqualified endorsement to this volume as a guide to the use of the x ray in diagnosis. He describes the stereoscope as employed for two plates which have been taken with the x ray tube shifted the distance that separates the human eyes. The two pictures are seen combined in one with perfect perspective and increased diagnostic value.

A similar effect is produced by standing about six feet away from plates set side by side and holding at arms length between the eyes and the plates a piece of cardboard, having in its centre a rectangular aperture about two by one and a half inches. The card must be adjusted till with the left eye closed the right eye sees the left hand picture framed by the aperture and the left eye similarly sees the right hand picture. On opening both eyes and looking fixedly at the aperture the two pictures will coalesce.

Radiology now being a necessary subject for British medical students, its use by them has been kept specially in view and it is admirably adapted for use as a textbook. The value of the book to the general practitioner lies in its excellent chapters on diagnosis.

The description of x ray apparatus and technic is complete. There is an excellent special chapter on diagnosis of the alimentary system. The book is not intended as a guide to the therapeutic use of the röntgen ray.

EYE DISEASES

Diseases of the Eye. A Handbook of Ophthalmic Practice for Students and Practitioners. By George E. de Schweinitz, M.D., LL.D., Professor of Ophthalmology in the University of Pennsylvania. Tenth Edition, Reset. With 434 illustrations and 7 colored plates. Philadelphia and London: W. B. Saunders Company, 1924. Pp. 865.

Manual of Diseases of the Eye. For Students and General Practitioners. By Charles H. May, M.D. Director and Visiting Surgeon, Eye Service, Bellevue Hospital, New York. Eleventh Edition, Revised. With 374 illustrations, Including 23 Plates with 73 Colored Figures. New York: William Wood and Company, 1924. Pp. iv-445.

The tenth edition of de Schweinitz's deservedly popular textbook of ophthalmology has been most thoroughly revised and brought up to the very last minute, as it were. It thus embodies in its contents, along with the revised and rearranged material from previous editions, everything of recent date that has been sifted and found of real value to the practising ophthalmologist. A great deal of the latter material has not as yet found its way into any of the extant textbooks, and the "predigested" treatment by the author of such subjects as Gullstrand's diaphragm lamp, contact illumination, ophthalmoscopy with red free light, Barraquer's method of extraction of cataract by suction, O'Connor's "cinch" shortening operation, etc., not only places the reader *au courant* with the advance of ophthalmology, but obviates the necessity of hunting for them through periodical literature and transactions of various medical societies.

It would be work of supererogation to pick out any portion of the book for special praise, but the chapters on refraction, diseases of the cornea, glaucoma, cataract, and sinus diseases in their relations to the eye, have particularly impressed the reviewer with the conciseness of their contents, lucidity of style, and preciseness of expression.

The make up of the book as to print, paper and illustrations, is of the high order we have grown accustomed to expect from the publishers of this volume.

* * * *

The eleventh edition of May's well known manual fully justifies the popular esteem in which it has been held by the profession since its first successful launching in 1900. The author, indeed, solved the problem of presenting to the general practitioner an excellent compilation of all that is essential and practically important in ophthalmology, in a lucid and easily intelligible style, supplemented by numerous illustrations, plates and colored figures that still further help in elucidating the contents of the text. The edition has been thoroughly revised and

brought up to date, every page having been carefully gone over by the author. The work occupies a unique position as probably one of "the best medical sellers," and this distinction it has acquired exclusively by its own merits which render it indispensable to every general practitioner into whose hands fall many eye cases before they come within the ken of the specialist.

BOTANY

The Pharmacist's Botany. By George B. Rigg, Ph. D., Associate Professor of Botany, University of Washington. New York and London: The Macmillan Company, 1924.

Botany and medicine have been intimates from the days of the primitive medicine man to the present. All of the ancient physicians and many of the moderns have been keenly interested in this branch of natural history and have derived from their observations much pleasure and profit.

As a subject for the premedical curriculum it should not be neglected and it is with pleasure that we commend this manual, which although primarily devoted to the needs of pharmacy students nevertheless will prove of service to the student of medicine.

THE CANCER PROBLEM

El Problema del Cancer. Por William Seaman Bainbridge, A.M., Sc.D., M.D., C.M., LL.D. Apendice: La Terapeutica Fisica de las Neoplasias Malignas. Por el doctor Vicente Carulla Riera. Barcelona: Cervantes, 1924. Pp. 646.

This is an annotated translation of the third English edition of Bainbridge's work with an appendix by Vicente Carulla Riera, Chief of the Physical Therapeutic Service of the Faculty of Medicine of Barcelona, on *Physical Therapy in Malignant Neoplasms.* Malignant disease is taken up from every possible angle including the historical and zoological, and the plates and illustrations of the English edition are retained in the Spanish translation. The bibliography is remarkably complete and there is an index of authors as well as of publications, which is a feature where American treatises usually excel. The book is of interest, not only from the importance of the subject but from the high standing of the author as an able writer on medical subjects and from his wide surgical experience.

The paper, impression and binding are better than the usual run of European medical works and its Spanish text will serve to bring it to the profession not only of Spain but also of the rapidly growing and progressive republics of the Western Hemisphere in whose language it is written.

SURGERY

Dictionary of Treatment. Including Medical and Surgical Therapeutics. By Sir William Whitla, M.D., D. Sc., M.P. Seventh Edition. New York: Paul F. Hoeber, Inc., 1924. Pp. 1100.

The object of this book is a worthy one and there are many valuable suggestions for treatment, but the attempt is made to cover too much territory, for instance, to advise the treatment, in a book of this character, of such things as cataract, symblepharon, and clubfoot. No space is lost in introducing a subject, and the treatment advised is direct and brief and mostly commendable, but surgical advice so briefly given can be of but little value. One regrets the author's impartiality in recommending many treatments for diseased conditions in order to cover a large number of undigested recommendations. One would wish he had more frequently given his approval or disapproval of a treatment.

It is impossible carefully to review this book which is almost an encyclopedia of suggestions for the treatment of everything from gunshot wounds to abortion, from corns to cheiropompholyx, and from epistaxis to epispadias.

The treatment of many diseased conditions is thoroughly and well discussed, but the author, with his long practical and clinical experience, could well abstract the book to half its size, which would not detract from, but rather increase its value.

FRACTURES AND DISLOCATIONS

Dislocations and Joint Fractures. By Frederic J. Cotton, M.D. Second Edition. With 1393 Illustrations from Drawings by Author. Philadelphia and London: W. B. Saunders Company, 1924. Pp. 745.

Cotton has a pleasing style and the ability to forcefully express his opinions and methods of treatment. The book is well illustrated with drawings, x ray reproductions and photographs. He takes up the different portions of the skeleton in a very systematic manner, dealing first with dislocations and then fractures.

It is obvious from a study of this work that Cotton is not a great believer in the traction method of treating fractures. No notice was made in the fracture of the surgical neck of the humerus of traction and external rotation, which the reviewer believes often gives better results, as it prevents the contraction of the lower portion of the capsule. In clavicle fractures one is surprised to see that there is no mention made of the cross splint, recently developed, which tends to give a better type of union. As a whole the book is satisfactory and gives a comprehensive study of fractures about joints and dislocations.

BIOCHEMISTRY

Handbuch der Biochemie Des Menschen und Der Tierce. Auflage 2; Lieferung 5-10, 14 und 15. Edited by Dr. Carl Oppenheimer. Jena: Gustav Fischer. 1923 and 1924.

Parts 14 and 15 of the well known Oppenheimer *Handbuch der Biochemie* have just appeared, the preface being dated April 24th, and a footnote is appended to a number of the articles stating that the revision has been brought down to March 18, 1924. There is no especial change in the form from the first edition. While the very elaborate bibliography does contain many references to the German work up to 1924, some of the most important American chemical papers are not referred to. There is, however, a good deal of variation between the different authors, as is inevitable in a handbook of this kind. For example, the article on Animal Ferments by the editor is extremely good, and it contains an abstract of almost all of the recent important American work. Other sections are but little changed from the first edition. Despite these irregularities these numbers give promise that the completed text will remain as a great source book for information on biochemical matters. Parts 5 to 10 date from 1923.

HIGH ALTITUDES AND TUBERCULOSIS

Das Hochgebirgsklima. Physiologische Einflüsse, Indikationen und Kontraindikationen. (Erfolge und Dauerresultate bei Tuberkulose-Erkrankung.) Von Dr. O. Amrein, Chefarzt des Sanatoriums Altein, Arosa. Arosa: F. Junginger-Hefti, 1922. Pp. 40.

In this monograph the value of the climate of high altitudes in the treatment of tuberculosis is emphasized. After discussing the physiological effects of residence at a high altitude on the various vital organs of the body, the author dilates upon the indications and contraindications and also the temporary and permanent results of high altitude therapy in tuberculosis of the different organs. This is an excellent treatise and well worth reading as the value of this form of treatment is constantly gaining recognition. The bibliography is extensive.

HOME TREATMENT OF TUBERCULOSIS

Domiciliary Treatment of Pulmonary Tuberculosis. By F. Rufenacht Walters, M.D., M.R.C.P. Second Edition. New York: William Wood & Co., 1924. Pp. 288.

This is the second edition of a very useful work, the first edition having had quite a large circulation in England as well as in the United States. The book, although intended for the medical profession, is written in language comprehensible by the intelligent layman. The first chapter is devoted to the etiology of the disease, followed by a review of the well known diagnostic signs and symptoms. The author wisely insists upon a study of the home conditions before consent is given for the patient to remain at home and install treatment there. He makes an interesting statement which might be taken to heart by all phthisiotherapeutists prior to giving a definite prognosis. It is as follows: "It has been often asserted that the chances of recovery depend on early diagnosis; but although this is true, it is not the whole truth. There are many cases which will do badly even if discovered early, and others which, though discovered after a long time, yet make a good recovery."

Of sea voyages as a means to cure tuberculosis, the author does not speak too favorably and he strongly condemns this method of travel for advanced cases. In his chapter on climate, he does not advance anything that is not known and practised every day by up to date phthisiotherapeutists. In the chapter on open air he maintains that the effect in hyperventilated rooms is equal to that in an outdoor shelter. It is very gratifying to see the author emphasizing the fact that there is no danger of contracting tuberculosis from a consumptive individual even at home if the necessary precautions are taken.

In the chapter on diet the following sentence might well be remembered by physicians as well as patients: "A patient's own idea as to the amount of food he needs is not trustworthy; it may indicate what he can easily digest, but not what his body should get. The appetite is no guide to the digestive capacity of the stomach, as shown by the success of Debove's method of *suralimentation* by means of an esophageal tube." In the reviewer's experience it is not necessary to demonstrate this maxim by the Debove method. Urging the patient to eat regularly, even if the appetite is wanting, suffices in the majority of cases.

In the chapter on specific remedies Dr. Walters devotes considerable space to the use of tuberculin in its various forms without committing himself to any one particularly, but concerning the use of tuberculin in general he says: "Since many slight cases get well under hygienic treatment alone, and many cases are not suitable for tuberculin treatment, it is more especially in the slowly progressing groups that the treatment is indicated, i.e., those who cease to make progress under hygienic conditions, or who get relapses." Besides mentioning the various tuberculins, he also devotes some pages to the description of Marmorek's, Maragliano's, and Bruschettini's sera and Spengler's I. K. treatment.

Under general remedies the usual drugs, such as creosotes, styracol, thyocol, benzosol, phenols, etc., are mentioned and doses given. A description is also given of the iodine group and arsenical remedies. The remaining chapters are devoted to family life, the care of children, and aftercare of the patient. A diet list is appended to the volume.

Taken as a whole, this second edition is more complete and up to date than the first, and it is well worth a careful perusal by all interested in the treatment of the tuberculous. The value of the book would have been materially increased had the author seen fit to illustrate some of the numerous devices, such as outdoor tents, home sleeping porches, window tents, etc., which so much facilitate the sanatorium treatment at home, or as the author chooses to call it, "domiciliary treatment."

MEDICINE

Ergebnisse der gesamten Medizin. Unter Mitwirkung hervorragender Fachgelehrten, herausgegeben von Prof. Dr. Th. Brugsch, Oberarzt der II. med. Klinik der Charité in Berlin. Fünfter Band. Heft 1, mit 12 Abbildungen im Text und 12 Kurven, 1923. Heft 2, mit 10 Abbildungen im Text und 6 Kurven. Hefte 3 und 4, mit 29 Abbildungen im. Text. Berlin und Wien: Urban & Schwarzenburg, 1924.

In the first part Franz M. Groedel thoroughly analyzes the theoretical basis of the action of carbonic acid baths in circulatory disturbances and also the proper technic of the treatment in the various types of disorders. Ludwig Hofbauer explains the nosological significance of apical catarrh and hilus disease of the lungs, asserting that only functional tests can give definite information regarding the proper etiologic functional therapy. Otto Schmidt writes about mastitis and the most recent methods of treating it. Gottwald Schwarz discusses the röntgenotherapy of exophthalmic goitre. Emil Bürgi describes the narcotics, dividing them into the fatty series (true narcotics), opium alkaloids, scopolamine and the solanaceæ bromides, cannabis indica, etc. Pluriglandular insufficiency is discussed by Leo Borchardt and he divides these cases into the thyrotesticulohypophyseosuprarenal and the thyrosexual types. He also discusses pluriglandular insufficiency as part of the disease picture of other conditions, such as infantilism, cretinism and hypophyseal tumor with pluriglandular insufficiency. Hans Elsner writes about the present state of gastroscopy, its technic and indications and the diagnosis of cancer and ulcer of the stomach. He also describes his own instrument. K. Fahrenkamp discusses hypertension—the arterial increase in blood pressure—as a symptom and its treatment.

In part two there is an article by Walter Wolff on the latent causes of fever. Rudolf Degkwitz discusses immunobiology and the immunobiological methods in diagnosis, prophylaxis and therapy of the infectious diseases of children. Arvo Ylppö is assigned the subject of icterus neonatorum. Arnold Durig discusses the application of the principle of division of labor (called in America the Taylor system) to the practice of medicine. D. Kulenkampff discusses the subject of trigeminal neuralgia in a most comprehensive manner. Carl Bachem describes various remedies recently introduced into therapeutic practice in Germany.

In the third and fourth sections a chapter on the latest drugs is concluded. W. Cimbal writes about the neuroses of the mental struggle, in which he differentiates between neuroses, nervousness, neurasthenia and hysteria. S. Isaac deals with the changes induced in diabetic therapy as a result of the introduction of insulin. The operative treatment of trachoma is discussed by A. Peters. Life insurance medicine is taken up by L. Feilchenfeld. The chapter on metabolic movement, distribution and changes, which gives a somewhat different aspect to metabolism from that usually considered, is written by W. Arnoldi.

The use of caramel in the treatment of diabetes is discussed by E. Grafe. W. Weitz discusses the importance of heredity in the causation of disease. S. G. Zondek writes about the fundamental principles of calcium therapy. Syphilis in the child is discussed by E. Müller. Bronchial asthma is taken up by W. Schultz. Denker and Nühsmann write about pharyngeal sepsis.

CHEMICAL ANALYSIS OF THE BLOOD

Handbuch der biologischen Arbeitsmethoden. Abt. IV. Angewandte chemische und physikalische Methoden, Teil 3, Heft 3. Edited by Dr. Emil Alderhalden. Berlin und Wien: Urban and Schwarzenberg, 1923.

This portion of Abderhalden's *Handbuch* deals with the chemical analysis of the blood, covering both the organic and inorganic constituents. It is well up to date, and unlike some of the other numbers, it refers very largely to the chemical methods which have been developed recently in this country. It forms a useful laboratory reference book on the subject.

LABORATORY METHODS

Guide Pratique d'Analyses de Chimie Biologique. By René Clogne. Paris: Librairie Le Francois, 1924.

This second edition of René Clogne's book is a useful collection of laboratory methods for those who read French with more facility than English. It is interesting to note that Clogne follows the method of attack chosen by American writers of such guides, that is, the description of each procedure is considered under the heading of, first, principle; second, necessary apparatus and reagents, and third, technic, following which the normal values are given. The methods chosen are clearly described. This edition contains a new chapter on the chemical methods of water analysis, and one on the detection in the urine of arsenic, cacodylates, bromides and iodides, chlorates, mercury, salicylic acid and its derivatives, and so forth.

STEKEL

Nervöse Angstzustände und Ihre Behandlung. Von Dr. Wilhelm Stekel. Vierte, Vermehrte und Verbesserte Auflage. Berlin und Wien: Urban und Schwarzenberg, 1924. Pp. 685.

Stekel is a voluminous writer. He has ideas—some original, some quite radical. He is always worth reading for he gives one food for thought. His spirit is to be admired. Though he at times seems flighty, one can always find a juicy kernel in the hasty turning over he has given his material. Orthodox analysts shout anathema, yet make use of much he has to offer. One must separate the chaff from the grain. Yet one cannot in truth deny that Stekel has a flair for this sort of thing. Anyone who is sincerely interested in the psychoneuroses and the most modern form of therapy will do well to read Stekel's work.

MEDICINE FOR THE LAYMAN

National Health Series. In Twenty Volumes. New York and London: Funk & Wagnalls Company, 1924.

The best way to give an idea of the value of this practical little series, prepared for supplying the layman with the basic facts of medicine and personal hygiene, is to give a list of the subjects covered by the set, and the names of the authorities who have contributed the discussions. The list follows:

Man and the Microbe: How Communicable Diseases Are Controlled, by C. E. A. Winslow, professor of public health in Yale Medical School; The Baby's Health, by Richard A. Bolt, M.D., director of the medical service of the American Child Health Association; Personal Hygiene; the Rules of Right Living, by Allan J. McLaughlin, M.D., Surgeon, United States Public Health Service; Community Health; How to Obtain and Preserve It, by Donald B. Armstrong, M.D., executive officer of the National Health Council; Cancer; Nature, Diagnosis and Cure, by Francis Carter Wood, M.D., director of the Institute for Cancer Research at Columbia University; The Human Machine; How the Body Functions, by W. H. Howell, M.D., associate director of the School of Hygiene and Public Health at Johns Hopkins University; The Young Child's Health, by Henry L. K. Shaw, M.D., professor of diseases of children at Albany Medical College; The Child in School; Care of Its Health, by Thomas D. Wood, M.D., professor of physical education at Teachers College, Columbia University; Tuberculosis; Nature, Treatment and Prevention, by Linsly R. Williams, M.D., managing director of the National Tuberculosis Association; The Quest for Health; Where It Is and Who Can Help Secure It, by James A. Tobey, M.S., administrative secretary of the National Health Council; Love and Marriage; Normal Sex Relations, by T. W. Galloway, Ph.D., associate director of educational measures of the American Social Hygiene Association; Food for Health's Sake; What to Eat, by Lucy H. Gillett, M.A., superintendent of nutrition, New York Association for Improving the Condition of the Poor; Health of the Worker; How to Safeguard It, by Lee K. Frankel, Ph.D., chairman of the National Council; Exercises for Health, by Lenna L. Means, M.D., medical director of the Women's Foundation for Health; Venereal Diseases; Their Medical, Nursing and Community Aspects, by W. F. Snow, M.D., general director of the

American Social Hygiene Association; Your Mind and You, by Frankwood E. Williams, M.D., medical director of the National Committee for Mental Hygiene; Taking Care of Your Heart, by T. Stuart Hart, M.D., president of the Association for the Prevention and Relief of Heart Disease; The Expectant Mother; Care of Her Health, by R. L. DeNormandie, specialist of Boston; Home Care of the Sick, by Clara D. Noyes, R.N., director of nursing, American Red Cross; and Adolescence; Educational and Hygienic Problems, by Maurice A. Bigelow, Ph.D., professor of biology and director of the School of Practical Arts, Teachers College, Columbia University.

Such an array of authorities in their special fields is sufficient to testify to the character of the treatment of the subject matter in the twenty little volumes. Any physician would do well to recommend these practical little books to his patients for information along both general and particular lines.

COSMOPOLITANISM IN THE MIDWEST

The Tattooed Countess. A Romantic Novel with a Happy Ending. By Carl Van Vechten. New York: Alfred A. Knopf, 1924. Pp. 286

One suffers from a variety of reactions in laying down this book, a mixture of rage and humility. We are baffled by the author's intentions.

The fashions of the nineties in Maple Valley, Ia., are minutely described. French novels had this town enthralled. It repressed and thoroughly submerged them in its unconscious. But they have a way of flaring out in the behavior of even the most modest, so that after all, nothing is astonishing in this ordinary book.

In the character of Gareth Johns, the boy seducer, or victim—we cannot be certain which he is—there is something grim and pitiful. He buys his way to freedom more studiously than any prostitute. He will use women everywhere, without pity, selfishly, as he has used his mother, whose life is the price of his permission to go to college. We can see no future for him. As for the tattoed countess, she will only be a little older, a little more jaded, but no wiser! Altogether such a regressive tale that we wonder how it ever came to be born.

FEMALE CHARACTERS IN WAGNER

Women Characters in Richard Wagner. By Louise Brink, Ph.D. Nervous and Mental Disease Monograph Series No. 37. New York and Washington: Nervous and Mental Disease Publishing Company, 1924. Pp. 125.

Psychoanalysis has been employed in a most scholarly fashion to interpret the actions of the varied female characters in Wagner. A most suitable selection this has been, for in no other author who comes to mind have so many types of womanhood been portrayed. From childhood to old age, in all their perplexing situations, their plans, hopes, love life, and disappointments, we follow the trail. Attachments to family members, the severance of the bond, the taking up of new relationships, new goals—all these are covered. So keenly has Wagner identified himself with the versatile characters that valid conscious and unconscious conflicts are covered with meticulous precision. We are fortunate in having so careful a worker as Dr. Brink essay the task and do it so thoroughly. To many readers this book will prove a real treat; to others, a revelation and an inspiration to carry the worker to wider fields.

Medicoliterary Notes.

At last we have a literary review that is really literary and that really reviews! It is called *"Books:* a weekly review of contemporary literature," and is issued with the Sunday edition of the New York *Herald Tribune.* Stuart Pratt Sherman, formerly professor of English at the University of Illinois, is the editor. All reviews of any length are signed and are written by authorities on the subjects covered by the books. Although *Books* is only a few weeks old, it has contained already a number of excellent reviews and criticisms of works on scientific subjects, including medicine and psychology. Among these have been a review and criticism by Dr. James Ewing of J. Ellis Barker's book on *Cancer,* another by Alexander Goldenweiser of Fritz Wittels' recent work on *Sigmund Freud, His Personality, His Teaching and His School;* and a series of articles on Sir William Osler as a bibliophile. One of the most useful columns of this new publication is entitled *Books of the Week,* a classified list of current works with a line or two of pertinent descriptive annotation.

* * *

The *Nation's Health* for September contains an interesting article by Alice Ravenhill, Fellow of the Royal Sanitary Institute, on *The Human Machine, How to Multiply Human Energy,* with a view to lessening the needless and futile expenditure of energy in many households which leads to ill health and general inefficiency. The writer has estimated that in inconveniently arranged homes the service of three meals a day to a family of six represents a total weekly load of one and a third tons; that the distance covered in the preparation of single light meal is about 127 yards; and that stair climbing in a week is equivalent to the ascent of a three thousand foot mountain.

* * *

One of the books of the month is *Little Novels of Sicily,* a translation by D. H. Lawrence of some of the best short stories by Giovanni Verga, published by Thomas Seltzer.

* * *

The State Boards of Health of Massachusetts and Connecticut have brought about the passing of a law requiring that no dealer shall sell clinical thermometers within the borders of those states without a seal engraved on each thermometer, the use of the seal being granted after the examination of a number of samples and revoked if thermometers are found bearing it and varying from specified conditions. Other states would do well to follow this example, for physicians have in recent years found marked carelessness in the manufacturing and standardizing of many makes of clinical thermometers.

* * *

Half a million readers have delighted in *Bob, Son of Battle.* Probably not one per cent. knew the author was a sick-room prisoner when he wrote it. Alfred Ollivant injured his spine in a riding accident just after being graduated from Woolwich with a commission in the Royal Artillery. He spent fourteen years flat on his back. At the same time he was writing himself into fame. He's just finished a novel, *Devil Dare.—Books, Herald Tribune.*

* * *

The *International Book Review* for September is a number of unusual interest. Benvenuto Cellini Enlivens Manhattan is the title of an article by Chester T. Crowell describing how he came to appreciate Cellini by reading him in Macdougal Street; Percy A. Hutchinson tells us about Joseph Conrad, Alchemist of the Sea; Roselle Montgomery writes of Sheila Kaye-Smith In and Out of Fiction; and Clifford Smyth in an editorial entitled A Dying and a Living Art laments the deterioration of the "colyumist" in the daily papers. Admitting that the daily column had originally high standards of literary excellence, the writer feels that now it has drifted into a sort of artificial decadence that must ultimately bring about its own extinction. "After

all," he says, "How can one be spontaneously witty, genuinely clever, all day and every day, without resorting finally to expedients that make spontaneity impossible."

* * *

The Canadian Council on Child Welfare has issued a chart showing the child labor laws of the various provinces, with their bearing on related problems, such as compulsory school attendance, educational requirements for children engaged in or entering employment, minimum age for factory workers and those in shops and office buildings, prohibition of night work, and kinds of labor in which children may engage.

* * *

A Berlin newspaper reports that the mortality rate of children in that city was doubled between the years 1914 and 1918. Out of 885,000 children, 30,000 were found to be tuberculous, and 80,000 otherwise diseased, while 130,000 were suffering from malnutrition.

* * *

A recent article on the new socalled synthetic lumber describes it as primarily the poor man's home building material; it is cheaper than natural lumber, and weighs only one fourth as much as pine, so can be transported with much less expense. It is an almost complete insulator of heat and cold, and a sound deadener.

* * *

A recent report from Washington shows that the month of August marks the peak of automobile accidents at grade crossings. In 1921, 229 persons were killed and 512 injured; in 1922, 213 were killed and 535 injured. During the whole year of 1923, 2,263 persons were killed and 570 injured in such accidents.

* * *

The *Atlantic* for September contains an interesting contribution by a writer who signs himself "90," entitled Ferguson Rex. It is a study of the presentday student in college, who, the writer admits, has his faults, but he finds these less pronounced than the corresponding ones of his prototype of the '90's.

* * *

For the first time since 1920 a drop has been registered in mortality from alcoholism, as shown by the figures for mortality experience for the first quarter of 1924.

* * *

The two literary personalities at present arousing the greatest interest in France seem to be the late Raymond Radiguet, poet and novelist of note at seventeen, whose last novel, *Le Bal du Comte d'Orgel*, a study in psychology, promises to sustain the reputation made by his first, *Le Diable au Corps*, a realistic study of precocious love; and Arthur Rimbaud, poet, drunkard, explorer, soldier, and commercial agent, who wrote some of the most beautiful poetry ever produced in France before he was nineteen years old, and then renounced literature.

* * *

A committee of New York City members of the American Association of Social Workers drew up a scheme for coordinating New York City social and welfare work which won the $1,000 prize offered by *Better Times*. The prize money will be spent in establishing the proposed central welfare council, which will have citywide functional divisions on health, child welfare, recreation, neighborhood activities, delinquency, and industrial welfare.

* * *

Among recent publications of interest (nonfiction) are *The Criminal as a Human Being*, by George S. Dougherty, former Deputy Commissioner and chief of detectives of the New York Police Department, taken from the official files and from memory (Appleton); *Straws and Prayer Books*, by James Branch Cabell, comments and reflections, philosophical and otherwise (McBride); *Scientific Research and Human Welfare*, by Franklin S. Harris, an outline of the progress of medicine and social hygiene during the last century (Macmillan); *The Conduct of Life*, by Benedetto Croce (Harcourt, Brace); *Racial Realities in Europe*, by Lothrop Stoddard (Scribner); *A Century of Work for Animals*, by Edward G. Fairholme and Wesley Pain, a history of the work of the Royal Society for the Prevention of Cruelty to Animals (Dutton); *Colloid Chemistry*, by Jerome Alexander (Van Nostrand); *The Inner Discipline*, by C. Baudouin and A. Lestchinsky, a discussion of "the new psychology" (Holt); *How to Keep Well*, by Dr. A. F. Currier (Century); *Economics of Fatigue and Rest*, by P. Sargent Florence, a study of labor in industry (Holt); *Yourself and Your Body*, by Dr. Wilfred T. Grenfell (Scribner); and *Parents and Sex Education*, by B. C. Gruenberg (American Social Hygiene Association).

* * *

In the recently uncovered buried city of Leptis Magna, an ancient Roman metropolis in the desert of Northern Africa, one of the most important finds from an artistic and historical point of view was a statue of Æsculapius, the Father of Medicine.

* * *

The National Child Labor Committee has recently published an interesting little book called *Poems of Child Labor*. These are not limited to any period or type, but all deal with the topic in hand. Among authors to be found in the collection are Elizabeth Barrett Browning, Robert Frost, and Arthur Guiterman.

* * *

Beginning September 30th, the New York City Department of Health opened an extension institute in industrial hygiene for nurses at Fordham University. All registered nurses are eligible. The course is an outgrowth of the large attendance at the lectures on industrial hygiene for nurses given at the university during 1921 and 1922.

* * *

A mental hygiene survey of Wyoming made at the request of the Governor and with the participation of the Division on Mental Deficiency of the National Committee for Mental Hygiene has recently been completed.

* * *

Muirhead Bone, the well known British etcher and painter who was during the war an official artist on the Western Front, has an interesting article in the Manchester *Guardian* for August 6th on *Joseph Conrad—A Modern Ulysses*, which he concludes with the statement that "centuries may come and go before anyone so gifted, so strange, and such a charming human being as Joseph Conrad comes this way again."

* * *

In a recent report of the Department of Commerce it is stated that on January 1, 1923, there were 893,679 persons confined in Federal, State, city, county, and private institutions for defectives, hospitals for mentally diseased, institutions for feebleminded and epileptics, homes for adults and dependent or neglected children, institutions for juvenile delinquents, penal institutions, and almshouses. The report shows that, in addition, 4,973,032 patients were treated in hospitals during 1922, and there were 21,621,761 visits of patients for treatment in dispensaries.

* * *

The London *Times* has recently been running a series of articles on the Isles of Greece by Sir Arthur Shipley, who is well known also for his works on natural history. In one of these articles he tells of a visit to Crete, and emphasizes the fact that, Epimenides and St. Paul to the contrary, the Cretans "lied no more than any other people we came across, and they are an abstemious and thrifty folk." In confirmation of this statement, he tells us that, during the war, huge quantities of coal were thrown into the sea from the many battleships stationed there, and that the Cretans, being thrifty if not mechanical, retrieved this treasure by hitching a large octopus to a rope and lowering it over the coal deposits. As soon as the octopus had clutched bottom with its tentacles, it was hoisted to the surface again and relieved of the tightly clasped lumps of coal. This coal heaving process was repeated until the supply was exhausted.

A recent significant publication of the University of Chicago Press is the volume entitled *Origins of Sociology*, by Dr. Albion Woodbury Small, professor of sociology at the University of Chicago.

Abstracts from Current Literature

FRACTURES AND DISLOCATIONS

Fractures of Elbow Joint.—E. L. Gilcreest (*Surgery, Gynecology and Obstetrics,* October, 1923) says that as structure is subservient to function, it is only natural to presume that the maximum return of usefulness in a limb would be brought about by the exact reconstruction of the deformed bone, but as perfect reduction is not infrequently impossible or inexpedient, the chief aim should always be complete restoration of function.

For the treatment of fractures in the vicinity of the elbow joint, with the exception of fracture of the olecranon process, the fully flexed position offers the best results. Often a splint is unnecessary, the forearm being strapped to the upper arm and fixed to the chest with a bandage. The advantages of the flexed elbow position are: I. It gives the most complete anatomical reposition of fragments and the best fixation. 2. It favors the retention of the more important flexion function of the joint. 3. It cooperates with gravity in the subsequent restoration of function. In correcting the initial deformity the following procedures should be carried out: 1. Strong traction is exerted on the forearm with the elbow fully extended and supinated. 2. At the same time the joint is manipulated, the displacement being corrected as far as possible; usually the upper fragment is displaced forward and the lower backward. 3. While maintaining No. 1 and No. 2, the elbow is slowly but firmly flexed to an acute angle and so fixed with the forearm supinated.

As to how long this position of acute flexion should be maintained, of course, will depend somewhat on the case, but usually after about two weeks the forearm can be lowered a few degrees every four or five days. This should be continued until the arm can be fully extended.

In conclusion the author calls attention to the serious complications which may ensue from failure to reduce fragments by traction and flexion in a first operation. A satisfactory result is attained only when, after the fracture is healed, the range of motion is sufficient to bring the hand to the mouth in flexion and to place it in the trousers' pocket in extension.

Fractures of the Elbow.—C. W. Cutler and H. W. Cave (*Surgery, Gynecology and Obstetrics,* May, 1924) discuss the diagnosis and the different types of elbow fractures. They report on several cases in which every effort was made to produce and maintain hyperflexion after reduction, the advantages of this method of treatment being as follows: 1. By this position the tendency of the forearm when extended to press backward the distal fragment is done away with. 2. The tendinous expansion of the triceps is put on tension and acts as a firm splint or sling in holding the reduced fragments in place. 3. In fractures above the condyles the periosteum is stripped up above the line of fracture. If not restored to its normal position by hyperflexion, this may lead to callus formation which will subsequently embarrass function. 4. A certain amount of stiffness is bound to follow these fractures, because of injury to soft parts and extravasation of blood and effusion in the joint. If, at the start, flexion is assured, the more useful functions of the arm are maintained. Subsequent mobilization in the range of extension is more easy and is aided by the rational forces of gravity and the relatively strong pull of the triceps.

A New Splint for Fracture of Humerus.—C. R. Steinke (*Surgery, Gynecology and Obstetrics,* June, 1924) says that this splint is applicable for fractures of the humerus and clavicle in the newborn. The splint is permeable to the x ray, and seems to meet most of the requirements for the proper reduction and retention of the fragments. The curved wire is covered with muslin or cheesecloth to support the head. The inside measurement is six and a quarter inches across. The lateral arm piece is adjustable as to length and angulation of the arm with the body. It may be adjusted for the right or left arm. The two perforations in the upright piece at the outer end of the extension are for the attachment of a windlass; or a rubber banjo type of extension may be employed. The arm extension is eleven inches in length when it is closed up and thirteen inches long when it is extended, and is one and three quarter inches wide. The body piece is also adjustable as to length, being six and a half inches long through its centre when closed up and eight and a half inches when the extension piece is drawn out. The width of the body piece is three and three quarter inches at the narrowest point and four and a half inches at the widest.

The infant is bandaged to the body piece and the extension is applied to the arm. Coaptation splints are used at the point of fracture in the humerus. The fragments can be adjusted under the fluoroscope and when they are in good position the body and arm of the infant, along with the splint, are encased in plaster of Paris. This allows for easy handling and caring for the baby who can be placed at the mother's breast without inconvenience. The infant's toilet is easily and safely cared for as there is little danger of displacing the fragments after the plaster is employed. The method is applicable in bad fractures of the clavicle.

The Skate in Lower Extremity Fractures.—R. M. Yergason (*Surgery, Gynecology and Obstetrics,* April, 1924) says that maintenance of the foot in proper position is a problem invariably present in fractures of the lower extremity. With compound, comminuted fractures near the ankle and open splint methods of treatment the problem is particularly difficult. To meet the varying requirements of different cases, splints and traction methods, a skate has been devised, which, when properly attached to the foot with celluloid, allows leverage as well as traction to be applied with all the effectiveness and none of the dangers of the heel pin or the Finochietto stirrup. The skate will hold the foot in any position or combination of positions, with or without motion, with none or with any method of traction desired and in splints the side bars of which are either round or flat. The author hopes that the skate will prove as valuable to others as it has to him.

Complete Outward Dislocation of the Patella.—N. Winslow (*Annals of Surgery,* March, 1924) comments upon the rarity of this complication. He gives a detailed anatomical explanation of its rarity, and offers the following methods of treatment: In recent cases a closed reduction with or without anesthesia is generally feasible. When such efforts fail an open replacement must be made. This can be done either by a straight or a curved incision. Habitual luxation has been cured by nonoperative treatment, but usually requires an operation. Bajardi has accomplished a cure by cutting out of the inner side of the capsule an oval slice of redundant tissue and suturing the margin of the defect, thus created, together. Le Dentu has obtained satisfactory results by reefing the relaxed capsule. Albee splits up the front of the condyle and elevates the fragment until a wedge shaped hiatus is formed into which he inserts a chunk of bone cut from the tibia, holding the graft in place with a pin. In some instances it has been found necessary to chisel off the tubercle of the tibia and transplant it upwards. While these methods, either alone or in combination, generally suffice to effect a cure, on occasions some more complicated technic needs to be exploited. Whenever a rent is found in the capsular ligament, be it in a fresh dislocation or in a recurrent displacement, the hole must be sewed up, regardless of what else is done.

Simultaneous Dislocation of Both Shoulder Joints.—A. P. Heineck (*Annals of Surgery,* May, 1924) makes a study of fifty-eight cases, reaching the following conclusions: The prognosis in bilateral shoulder dislocations is influenced by many factors, chief among which should be mentioned the age of the patient and of the dislocation, the patient's occupation, the associated injuries and the treatment instituted. As a rule, the older the patient the longer the period required for recovery. As to the age of the luxation, it is agreed that dislocations call for immediate reduction. Sequelæ are thereby forestalled; nothing is gained by delay. Convalescence is slower in handworkers than in intellectuals; delicate hand movements are late in returning. Associated injuries require appropriate treatment. In some cases full function is not restored before the detached muscles or tuberosities are permanently fixed in their normal place. Bloodless manipulative methods, supplemented by electrotherapy, mechanotherapy and hydrotherapy give the best results. The two dislocations, right and left, are reduced

separately, usually by the same method and at the same sitting. The duration of immobilization varies in different cases: twelve days, five weeks, etc. The author is of the opinion that most clinicians err in prolonging complete immobilization beyond two weeks. About the tenth day gentle passive motion and massage and electrical treatment should be instituted. After an arthrotomy and division of extensive adhesions, even though the bone is replaced to its normal position, some joint stiffness is to be expected. This is generally compensated for by a movable scapula. The restoration of the rotundity of the shoulder and the absolute relief of pain give much satisfaction to the patient. After reduction of the dislocations both shoulders are immobilized during the period of repair, the arms fixed in front of the chest by adhesive plaster, bandages, etc., for from two to three weeks. The patient is practically helpless, he cannot feed himself, he cannot dress himself, he cannot attend to many of his other needs; he must be provided with an attendant.

Healing of Fractures.—A. Kolodny (*Journal of Bone and Joint Surgery, October,* 1923) reports on an experimental study of the periosteal blood supply as follows: 1. An adequate blood supply of the periosteum is essential for normal union of fractures. 2. The periosteal callus plays a far greater rôle in the union of fractures than the endosteal callus.

Recurrent Dislocation of the Shoulder.—W. R. McAusland (*Surgery, Gynecology and Obstetrics,* June, 1924) offers the following conclusions: From a study of the literature of this subject, it appears that the treatment of recurrent dislocation of the shoulder has been one of varying technic. No consistent method, adaptable to a large number of cases, has been reported. On the contrary, each treatment differs according to the importance attributed by the surgeon to the pathological condition of the bone, capsule, and muscle. The majority of cases have been treated by some form of capsulorrhaphy, and in most of them satisfactory results have been obtained.

THE ANEMIAS

Sickle Cell Anemia.—John G. Huck (*Bulletin of the Johns Hopkins Hospital,* October, 1923) discusses the etiology, pathology, blood findings, symptomatology, diagnosis, prognosis, and treatment of sickle cell anemia. To the four cases already on record, he adds fourteen from the Johns Hopkins Clinic, two of which are reported in detail. From experimental studies Huck concludes that the sickling of the cells is an inherent property of the red blood cells, and that the patients' sera are without effect on normal erythrocytes. Attempts to transmit the disease to animals were unsuccessful. Sickle cell anemia is a specific disease entity, thus far described only in the negro race. It is transmitted according to the Mendelian law.

Anemia in Nephritis with Nitrogen Retention.—C. Aubertin and J. Yacoel (*Bulletins et mémoirs de la Société médicale des hôpitaux de Paris,* June 19, 1924) report cases showing that in many instances of nephritis of the azotemic type the accompanying anemia, though clinically manifested only in a distinct pallor of the patient, is nevertheless sufficiently pronounced to lower the erythrocyte count to about two milions. These cases constitute a transition stage between the mild anemia of Bright's disease and the pernicious anemia of cases with severe nitrogen retention. In general, the anemia and azotemia show simultaneous progression. On the other hand, in chronic nephritis without nitrogen retention, anemia is generally absent.

Pernicious Anemia.—An analysis of the clinical histories of patients with pernicious anemia in the Johns Hopkins Hospital, from 1918 to 1922 inclusive, by Charles R. Willson and Frank A. Evans (*Bulletin of the Johns Hopkins Hospital,* February, 1924) is based on the histories of one hundred and eleven patients with pernicious anemia, eighty-two men and twenty-nine women, of whom eight were negroes. Seventy-one per cent. of the cases occurred between thirty and sixty years of age. There were only five patients who had had other members of their families die from anemia. The analysis of the clinical and laboratory findings is too detailed to abstract, but the authors have summarized a few of the points demonstrated by the study as follows: The anemia once established practically never completely regenerates. Anisocytosis and poikilocytosis are constant findings; basophilia is rather uncommon; a leucopenia is a characteristic finding. An eosinophilia as high as seventeen per cent. may be found, but an actual increase in eosinophile cells is rare. This also applies to the large monouclear and transition cells. Myelocytes, as high as ten per cent., are occasionaly found. Free hydrochloric acid in the gastric contents of these patients is so rare that, when present, it should put the diagnosis under suspicion. The spleen is palpable in only about twenty per cent. of these patients, and the liver in about thirty-three per cent. All patients, whatever other discomforts they may suffer, have one or more of the following symptoms: weakness, disturbances in digestion, and nervous disorders of the extremities.

Pernicious Anemia.—Charles F. Martin (*Medical Clinics of North America,* May, 1924) summarizes his findings as follows: The blood picture of pernicious anemia is not pathognomonic *per se* and where no etiological factor is found and the course of the disease is characteristic, and where in addition, the type of anemia is "hemolytic" the diagnosis of idiopathic or pernicious anemia may be made.

In the treatment, the various forms of arsenic have given some degree of success. Hydrochloric acid in sufficiently large doses is of great value in counteracting the effects of the achylia. The results of transfusion are: 1, Improvement in the symptoms—noises in the ears, vertigo, the nervous symptoms, and the general condition; 2, a gradual rise in the blood count, and 3, longer remissions, often lasting for several years. The immediate results of splenectomy are: 1, Improvement in the symptoms and general condition; 2, improvement in the red cell count; 3, diminished urobilin in the duodenal content, in the feces, and in the urine; 4, increase in the number of nucleated red cells in the peripheral blood. Complete cures are apparently rare, but life is often prolonged.

Splenectomy should be attempted under the following conditions: 1, Only after focal infections have been removed; 2, when transfusions have already been tried and found beneficial; 3, preferably during a remission and when the blood is in relatively good condition; 4, probably the earlier the splenectomy, the better. Splenectomy should not be attempted under the following conditions: 1, In the aplastic type of anemia; 2, where the spinal cord changes are marked; 3, where transfusions have failed to give benefit.

Sprue and Pernicious Anemia.—Byrom Bramwell (*British Medical Journal,* March 1, 1924) believes that there is a close relationship between sprue and pernicious anemia. The profound anemia in both conditions appears to be due to the absorption of some blood destroying toxin. In both diseases the blood destruction seems to take place chiefly in the portal circulation, with resulting deposits of pigment in the liver. In pernicious anemia, as in sprue, the author believes that the mouth and tongue lesions are probably part and parcel of the lesions in the gastrointestinal tract. In both conditions, the etiologic factor seems to be a blood destroying toxin which is derived from the gastrointestinal tract and the clinical history of both have many points in common. It is suggested that in cases of Addison's (pernicious) anemia parathyroid extract should be tried as the author had some very favorable results with it.

Relationship of Some Hemolytic Disorders to Pernicious Anemia.—P. N. Panton, A. G. Maitland-Jones and George Riddoch (*Lancet,* March 15, 1924) review five groups of cases as examples of obscure hemolytic disorders related to pernicious anemia. The generally accepted evidence for this view is the serious diminution of erythrocytes, in the absence of external blood loss, associated with signs of greatly increased red cell formation as shown by hyperplasia of the red marrow and the presence of abnormal and immature red cells in the peripheral circulation; also by increased pigment excretion in the urine, coloration of the blood serum, the deposition of free iron in the viscera, splenic enlargement, and red cell phagocytosis. In the first group there are the blood changes of pernicious anemia, jaundice and hemoglobinuria. The second group were cases of arseniuretted hydrogen gas poisoning. The third group showed severe internal hemolysis of years' duration with partial storing of the broken down blood pigment in the skin instead of in the viscera. The fourth group were cases of socalled paroxysmal hemoglobinuria. One case

of the fifth group the diagnosis lay between pernicious anemia and acholuric jaundice. The fact that this was of the familial type suggests a different etiological factor. The important factors in the determination of the clinical picture are the main incidence of the lesion and the rapidity of the pathological process.

The Platelet Count in Cases of Pernicious Anemia, Using Thomsen's Method of Counting.—Hobart A. Reimann (*Buffalo General Hospital Bulletin,* January, 1924) found that the platelet count varies widely in pernicious anemia, the lowest count being 800 and the highest 333,000 to the cubic millimetre in different cases, and that it may vary between 80,000 and 250,000 in the same case at different times. He also showed that the number of platelets usually increases in proportion to the number of erythrocytes and in inverse proportion to the excretion of urobilin. The relationship of platelets and erythrocytes has been frequently observed by others and is interpreted as an indication of the activity of the hematopoietic system.

The Value of Germanium Dioxide as a Therapeutic Agent in the Anemias of Childhood.—Herbert W. Schmitz (*The Journal of Laboratory and Clinical Medicine,* March, 1924) presents the results obtained by the use of germanium dioxide in thirteen selected cases of anemia in childhood, given by mouth in 0.2 per cent. water solution. The dose ranged from thirty to sixty mg. daily, or every other day, until about three hundred to one thousand mg. had been administered, based on one hundred to one hundred and fifty mg. to the kilo of body weight. All the cases studied, except one of von Jaksch's anemia, showed a definite response by marked and sustained increases in the number of red blood cells and in the hemoglobin content. The most notable results were obtained in the cases of anemia following malnutrition and acute infections. Some clinical improvement was noted in a number of cases.

Addison's (Pernicious) Anemia and Subacute Combined Degeneration of the Spinal Cord.—Arthur F. Hurst (*British Medical Journal,* January 19, 1924), states that symptoms referable to the spinal cord are frequently found if carefully looked for and that anemia is also frequently found in degeneration of the spinal cord. Subacute degeneration is often associated with a family history of Addison's anemia. The author does not believe that oral sepsis and glossitis are specific symptoms in Addison's anemia, but he believes that achlorhydria is an essential predisposing cause of Addison's anemia and subacute combined degeneration of the spinal cord and is due to the loss of the antiseptic action of the gastric juice, which enables the bacteria to reach the stomach from the mouth in the presence of oral sepsis and thus to infect the intestine. The combination of achlorhydria and oral sepsis favors the development of Addison's anemia in the presence of a special streptococcus, which produces hemolytic and neurotoxic poisons when it reaches the intestine. When the production of the toxins is arrested, the blood shows spontaneous improvement. Symptomatic treatment accelerates the improvement.

NEUROLOGY

Transient Postpartum Paralysis of the Recurrent Laryngeal Nerve.—Karl Herold (*Zentralblatt für Gynäkologie,* March 15, 1924) reports a case showing an afebrile paralysis of the right vocal cord. It was presumably due to the strain of labor even though the labor was not very difficult. The hoarseness disappeared spontaneously in about two weeks and therefore it could not be definitely decided whether it was due to a circumscribed cerebral edema, a slight paralysis, or a peripheral toxic effect. The laryngological and neurological examinations were negative.

Recklinghausen's Neurofibromatosis.—B. Brooks and E. P. Lehman (*Surgery, Gynecology and Obstetrics,* May, 1924) give several illustrated histories and discuss them from the point of view of bone involvement. They conclude that these observations emphasize the fact pointed out by Gould that Recklinghausen's neurofibromatosis is a condition affecting bone as well as skin and nerve. The fundamental process in the disease is one of tumor growth. It has long been known that the result of this tumor growth is to produce characteristic clinical manifestations in the skin and nerves. These observations indicate that equally characteristic clinical manifestations develop in the bones. The recognition of these changes in the bones is of diagnostic importance, particularly in those instances in which the complete clinical picture, heretofore considered classical, is not developed.

Intractable Pain Relative to Rhizotomy and Spinal Section.—R. C. Shaw (*British Journal of Surgery,* April, 1924) shows that the posterior roots are actively concerned in the conduction of stimuli in most cases. Early or late recurrent pain, of ten without psychical disturbances, indicates the presence of some other conducting channel. In concluding the case for rhizotomy the following facts must be weighed: 1. In cases of stump neuralgia of the upper or lower limbs all ventral and dorsal roots should be severed, if the prognosis is at all favorable, in every case. This procedure will abolish intractable stump neuralgia of a thermalgic type; but there may be a residual pain due to sympathetic mediation, in which case, if the opportunity presents, where there has been a double cervicodorsal rhizotomy, the extirpation of the last cervical and the first dorsal sympathetic ganglia should be considered. 2. Posterior rhizotomy is occasionally successful for limb neuralgias, but the prognosis is completely uncertain. 3. In only rare cases is a localized rhizotomy for localized pain successful. 4. In tabes cases the considerable proportion of successes after posterior root section justify the operation in localized unilateral cases. 5. This should be accompanied by anterior rhizotomy. 6. The great disadvantage is considerable exposure of the cord necessary for extensive root section, with consequent shock. If the pain stimuli are intercepted, the anterolateral column of the spinal cord muust be considered.

Epidemic Encephalitis with Painful Abdominal Spasm.—Arthur J. Hall (*Lancet,* March 29, 1924) observed an epidemic of encephalitis in which abdominal myoclonus was a very prominent symptom. The muscles affected were either the upper part of the rectus abdominis, unilaterally or bilaterally, or the left external oblique. The spasms recurred at frequent intervals and varied in depth and in regularity. With bilateral involvement of the upper recti muscles the spasms were often synchronous but they may alternate from one side to the other. The cases that showed nothing else than the painful abdominal myoclonus (of Cruchet) were identical with other forms of the disease. The stigmata of the disease were quite plainly evident.

Histological Study of the Central Nervous System in Experimental Botulinus Poisoning.—E. V. Cowdry and F. M. Nicholson (*Journal of Experimental Medicine,* June, 1924) state that except for a slight degree of vascular engorgement all the lesions noted in the brains of mice, guineapigs and rabbits suffering from botulinus poisoning are readily susceptible of some explanation other than that they are produced by the direct action of the toxin upon the central nervous system. This absence of microscopical evidence of a central action of the toxin is not, of course, conclusive proof that the cells in the brain are not primarily involved, as it is conceivable that, owing to the delicacy of the nervous mechanism, the toxin might well act centrally without leaving any traces microscopically visible. The observations tend to show that there is no histological evidence inconsistent with the results of physiological experiments indicating that the site of action of the toxin is upon peripheral nerve terminals.

Management of Injuries to Cranium.—J. O. Bower (*Annals of Surgery,* October, 1923) presents ten cases with the following summary:

1. In injuries to the cranium or its contents, lumbar puncture with spinal fluid pressure observations is essential to proper management.

2. In certain cases, withdrawal of fluid may so reduce intracranial pressure as to render operation unnecessary; in borderline cases it is a means of determining early the least degree of intracranial tension; blood pressure readings at definite intervals may accomplish this in part, but one may have an increase in intracranial pressure and no corresponding increase in blood pressure.

3. Cerebrospinal pressure observations are important before and after plastic operations on the skull.

4. Finally, repeated examinations of the spinal fluid for microscopic blood are of importance in differentiating the less severe types of cerebral trauma.

Communication Between the Vagus and the Cervical Sympathetic.—R. C. Shawe (*Lancet,* March 29, 1924), asserts that the importance of the vagosympathetic fibres depends upon their two main spheres of distribution: first, to the cardioaortic region, and second, to the thyroid gland. In the former association they mediate, at least in some cases, as shown by the success of Jonnesco's operation, the critical nervous impulses of angina pectoris, transmitting the afferent stimuli from the heart and aorta, and probably transmitting efferent stimuli to that region. These nerves form a concentration point for the sympathetic cardiac fibres from the upper dorsal segments, and as such present a readily accessible isthmus at which to attack the vicious cycle of irritation by surgical methods. In the latter association these same communicating nerves probably mediate secreting fibres to the thyroid, and it is the pathological hyperexcitability of such fibres which may form a most important etiological factor in the production of exophthalmic goitre; consequently, in suitable cases, in association with the other sympathetic ganglia, their extirpation would appear to be justified in this disease, as judged by the results of Jonnesco's work.

Pain in Upper Abdomen and Chest.—C. H. Peck (*Surgery, Gynecology, and Obstetrics,* February, 1924) points out that the pain in the upper abdomen or chest is an outstanding symptom common to many pathological conditions not always easy to differentiate, that a number of nonsurgical conditions may cause upper abdominal pain, gives a comprehensive survey of the pains of abdominal diseases, and concludes: Upper abdominal pain must never be taken lightly or casually. Many cases are due to lesions which call for prompt surgical intervention. Many, when first seen by the surgeon, are masked by the previous administration of narcotics. On the other hand, surgical intervention without proper preoperative study and diagnosis on the plea of exploration, may mean unnecessary operation for some trifling nonsurgical condition and should not be tolerated.

Etiology of Stammering.—M. Sachs (*Wiener klinische Wochenschrift,* January 31, 1924) points out that, although the speech centre is localized unilaterally in the brain, the act of speaking is the result of a pronounced bilateral innervation and muscular activity. As a result of this arrangement there may be incongruities in the formation of sound, which might explain some of the disturbances involved in stammering, just as in certain forms of squint of the eye. It is a noteworthy fact that a number of stammerers are lefthanded and also that many individuals who have lost the use of their right arm become stammerers.

Passage of Iodides Into the Cerebrospinal Fluid.—Henry Cohen (*Lancet,* January 19, 1924) injected fifty c.c. of a 10 per cent. potassium iodide solution intravenously and he withdrew the cerebrospinal fluid at intervals of twelve to sixty minutes and tested it with starch. The meningitides gave positive results; other diseases, such as tabes, disseminated sclerosis, meningismus and normal cases gave negative results. If the passage of the iodide occurred it was found to be less than 0.5 mg. to the 100 c.c. of cerebrospinal fluid. The concentration of iodides is many hundred times greater in the blood than in the cerebrospinal fluid. In view of the great diffusibility of iodide through tissue cells—witness their rapid excretion by the kidney—no physicochemical theory of the formation of cerebrospinal fluid will be satisfactory until it explains the phenomenon of the resistance of the cells of the choroid plexus to this salt.

Diagnostic Value of Sugar Concentration in Spinal Fluid.—Herbert B. Wilcox and John D. Lyttle (*Archives of Pediatrics,* April, 1923) show that normally the spinal fluid sugar concentration is about one half that of the blood and that its range of variation corresponds to that of the blood. In disease of the central nervous system there is no constant definite relationship between blood and spinal fluid sugar concentration, but there is an inconstant disturbance of the usual relation found in the majority of normals. In tuberculous meningitis there is a wide divergence, produced by the low spinal fluid content and the, at times, high blood content. In epidemic encephalitis there is an approximation, produced by the high sugar content of the spinal fluid—the direct opposite to the relationship seen in tuberculous meningitis. The relation between the sugar concentration in blood and spinal fluid in anterior poliomyelitis shows no consistent deviation from the normal.

The Kottman Reaction in the Insane.—A. M. Saunders (*Journal of Laboratory and Clinical Medicine,* March, 1924) recommends the employment of the Kottman test, which is used to determine the amount of thyroid secretion by physicochemical means. The technic is given, and is said to be simply and rapidly carried out. The test is of especial value in the insane and neurasthenic patients, and provides a method to estimate the frequency and extent of impaired function of the thyroid. Saunders has used it in four hundred cases on the blood serum, and in fifty cases on blood sera and spinal fluids from the same patients. Of the one hundred and five case giving a retardation, a little less than half were frankly hyperthyroid, with rapid pulse, excitability, and goitre. In most of the others there were very indefinite symptoms.

MALIGNANT GROWTHS

Giant Cell Tumor of Bone.—J. C. Bloodgood (*Surgery, Gynecology, and Obstetrics,* June, 1924), says that on careful reinvestigation of all his material he is unable to find a central lesion with an intact bone shell which resembles the giant cell tumor in the gross and more or less microscopically, that has not remained free from metastasis. Many of them are free of recurrence after curetting. Therefore, at the present time, if a surgeon explores a central bone tumor in which the x ray, palpation, and exploration exclude tumor tissue outside the bone shell, or the capsule about the bone shell is destroyed, he can be certain that the only possible sarcoma is one resembling in the gross and in the section the osteogenic sarcoma of the chondromyxoma type—a tumor easily to be distinguished from the giant cell tumor or ostitis fibrocystica. If this statement is true, it simplifies the diagnosis, because the cellular pathology of the giant cell tumor in a certain percentage of cases, especially under the high power, has been confusing to experienced pathologists, and even today is incorrectly diagnosed sarcoma leading to unnecessary amputation or mutilating resections. The mutilation is especially great when the resection is done in the jaw.

Hyperplasia of Breast Tissues (Mazoplasia—Chronic Mastitis).—G. Lenthal Cheatle (*British Medical Journal,* April 12, 1924) prefers the term mazoplasia to that of hyperplasia of breast tissues. There are three forms: 1, desquamative hyperplasia of the epithelium lining the ducts and acini; 2, permanent cysts of the duct and acinus; 3, those with the character of papillomata, and 4, nondesquamating epithelial hyperplasia. The author believes the latter to be a cystic condition and that a breast containing them should be removed because of the inherent danger. They usually show infiltration of the surrounding tissues and should therefore be regarded as part of a carcinamatous process. Both the duct and acinus are affected. The duct epithelium also becomes markedly papillomatous as well as lactiform. The term chronic mastitis, as usually understood, includes several totally different pathological changes. Generally, these breasts contain small cysts with an active epithelium. Even breasts containing big cysts ought to be amputated because unsuspected carcinoma and papillomata may be found in them. The presence of papillomata may be diagnosed by a careful examination of the ampulla and ducts of the breast. Frequently one ampulla can be felt enlarged and painful, manipulation of which gives rise to a bloody discharge from the nipple. The duct leading from the tumor containing ampulla is regularly enlarged and convoluted. The existence of one multiradicular papilloma of the breast is very rare and the presence of these signs are an indication for the removal of the whole breast and the axillary glands.

Fibroadenoma of the Stomach.—R. Matas (*Surgery, Gynecology and Obstetrics,* December, 1923) reports an unusual case of a pediculated polypoid fibroadenoma of the stomach of the ball valve type, causing an unusual and complex syndrome. He emphasized the following points.

It is the failure to realize that a benign and especially a pediculated tumor in the stomach may assume a very malignant aspect ending in death—that is largely responsible for the little attention that is given to these tumors in scanning the differential diagnosis.

The one salient fact that comes out of this discussion and that is to be retained by the surgeon in approaching a surgical gastropathy is that the most perfect clinical picture of cancer of the stomach may be imitated even to a fatal issue by a perfectly operable benign growth.

Strain and Family Differences in Susceptibility to Cysticercus Sarcoma.—M. R. Curtis and F. D. Bullock (*Journal of Cancer Research,* April, 1924). More than ten years ago Murray pointed out that by breeding together mice with cancerous ancestry an increase in the frequency of spontaneous cancer was observable in the descendants. Bullock and Curtis have approached the problem from another angle. They have taken a species of animals in which a sarcoma never occurs in the liver, except after prolonged irritation by the cysticercous form of Tænia crassicola. The average rat is not very susceptible to this irritation, rarely more than one per cent. reacting by the production of a sarcoma of the liver, but the writers, by the means of selecting those animals in which sarcoma did develop, and breeding together the descendants of such animals, infesting these descendants, and eliminating the ones which did not develop sarcoma, and breeding those which did, have obtained a strain of an astonishing susceptibility to this particular type of irritation. In one litter of this strain, out of nine animals, eight tumors were obtained. The paper is a model of scientific accuracy. All of the facts reported have been subjected to statistical analysis to show that the statements made are justified. The great interest of their discovery lies not so much in its application to heredity in cancer in human beings as in the fact that there has been discovered in one strain of animals a new biological reagent for inheritable tissue alterations, this reagent being the production of sarcoma following the irritation of the cysticercus of Tænia crassicola.

Endothermy in Neoplastic Diseases.—George W. Wyeth (*Annals of Surgery,* January, 1924), says that when we come to summarize the advantages of endothermy we find that by its quickness and cleanness of application, its accuracy of dosage, its reduction of the dangers of metastasis and the likelihood of recurrence, the rapidity of convalescence and the good cosmetic results, it has made for itself in the treatment of accessible neoplastic diseases a place which no other agency can fill.

Excretion of Lactic Acid in Carcinosis.—K. Glaessner (*Wiener klinische Wochenschrift,* April 10, 1924) reports the excretion of lactic acid in the urine in patients afflicted with carcinoma and in concerous mice following the intravenous injection of glucose solution. This is not to be found in persons not afflicted with carcinoma nor in healthy mice.

Malignant Disease of the Testis.—W. B. Coley (*Annals of Surgery,* September, 1923), says that the number of permanent cures following surgical removal of the testicle for malignant disease is comparatively small, the proportion being not over five to ten per cent. The author believes that this number of cures is not sufficiently increased by the radical operation of removal of the retroperitoneal glands by the abdominal route, to warrant the very considerable risk of such an operation. Long continued systemic treatment with the mixed toxins of erysipelas and bacillus prodigiosus, combined with thorough radiation of the abdomen and supraclavicular glands by radium or x rays, in his opinion offers a far better hope of permanent cure than any form of operative treatment alone. If one waits after operation until a recurrence has taken place, marked regression of these recurrent tumors, and in some cases complete disappearance, may be expected from radium treatment; but in the great majority of these cases, the regression or disappearance will prove only temporary and death from extension of the disease will occur.

Primary Sarcomatosis of the Leptomeninges.—Frank R. Ford and Warfield M. Firor (*Bulletin of the Johns Hopkins Hospital,* March, 1924), give the histories of four cases of this condition, and have collected from the literature and abstracted the histories of twenty-eight others. They state that the clinical picture is composed in varying proportions of signs of increased intracranial pressure, cranial nerve palsies, signs of meningeal irritation and of involvement of the cord and posterior spinal nerve roots. The pathological basis is a diffuse invasion of the cerebral and spinal leptomeninges and the subarachnoid spaces by malignant neoplasms resembling sarcomas, which metastasize by way of the cerebrospinal fluid. These growths are of doubtful origin, but many are probably gliomas. The diagnosis depends on the demonstration of "tumor" cells in the spinal fluid and the recognition of the clinical picture, which is variable but usually characteristic.

DIABETES

Blood Sugar and Diabetes.—J. Pal (*Wiener klinische Wochenschrift,* April 10, 1924) maintains that hyperglycemia, which is due to bound sugar (glycemia) is not the cause of the diabetic glycosuria. The cause should rather be sought in the presence of free sugar in the blood, which may be the result of either a splitting off of sugar from the glycemia or of an advance beyond the assimilating power. The diabetes of pregnancy is a condition analogous to the involvement of the island of Langerhans mechanism similar to that of the kidney in pregnancy.

Diabetes and Infantilism Treated with Insulin.—E. Apert (*Bulletins et mémoirs de la Société médicale des Hopitaux de Paris,* June 26, 1924) reports the case of a boy of seventeen years passing two hundred grams of sugar a day and weighing but twenty-nine kilograms. After one year of insulin treatment his condition was completely transformed. His skin previously so shrunken as to suggest gerodermia, became clear and rosy, and he gained eleven kilograms in weight, though only three centimetres in height. The infantile genitals showed beginning development. The glycosuria ranged from nil to twenty or thirty grams and the acetonuria disappeared. An operation under ether for undescended testicle was well borne. No remedy other than insulin had been administered.

Neurological Observations on the Pathogenesis of Diabetes Mellitus.—Otto Binswanger (*Schweizerische medizinische Wochenschrift,* March 27, 1924) asserts that glycemia is fairly independent of the rate of sugar production and disintegration. He ascribes to the nervous regulation of the blood sugar and the disturbances of this regulation which lead to diabetes the same rôle as to the hormones which act as activators to the central nervous system. He shows how constitutional inferiority may also involve all the organs that are concerned in the regulation of sugar, so that diabetes suddenly develops, how psychoneuropathy and glycosuria may be closely associated, and how "involutional diabetes" occurring beyond the fourth decade may be associated with a hereditary organic weakness of the endocrine system, frequently combined with psychicnervous elements (for example, climacteric melancholia with diabetes). Insulin acts as a stimulant to the parasympathetic system. A deficiency of insulin affects the metabolism of the liver and the parasympathetic centres at the base of the brain.

The Pancreas and Diabetic Metabolism.—Horst Oertel (*Lancet,* April 5, 1924) does not believe that insulin is a secretion of the islands of Langerhans and that it furnishes a product which "aids in the burning of blood sugar" and that the islands are not wholly independent structures, embedded in the pancreas. The islands are a phase in the constant morphological fluidity of the pancreas. Pathological evidence of island changes in diabetes as evidence of independent function is now discredited, as hyaline changes, very similar to those occurring in diabetes, are also observed in nondiabetics, especially in older persons or cachectics. However, the independent anatomical and functional position of the islands rests on an uncertain basis. The whole pancreas is in constant regression and progression, just like other endocrine organs. While normally these two processes proceed side by side in orderly physiological balance, they may become upset and, by exaggeration or inhibition of one or the other, lead to pathological states. The author believes that in this manner the essential atrophy of the pancreas develops which is more commonly found in severe diabetes of the young than the cirrhotic (inflammatory) atrophy. There is still a reasonable uncertainty in the exact mechanism of the relationship of the pancreas to sugar metabolism. There is enough morphological and experimental evidence to question the independence of the islands and the conception of them as organs of internal secretion which are essential for the combustion of sugar.

Arteriosclerosis and Diabetes.—Byron D. Bowen, Edward C. Koenig and Anne Viele (*Buffalo General Hospital Bulletin,* April, 1924), in a study of the lower extremities in diabetes as compared with nondiabetic states, from the viewpoint of x ray findings, with particular reference to the relationship of arteriosclerosis to diabetes, remark that their study appears to justify the clinical impression that diabetes, especially when uncontrolled, is a contributing

factor in the production of arteriosclerosis which is usually of the senile type. The relationship between diabetes, arteriosclerosis, and gangrene seems to be very close and suggests the following sequence: first, the diabetes contributing to the arteriosclerosis, and secondly, the combinations of the two diseases favoring gangrene. The data on the cases of arterial hypertension, when compared with the data on the nonhypertensive group, strongly suggest that diabetes, when associated with arterial hypertension, as it frequently is, pursues a definitely progressive course, and that the combination tends to the production of arterio-arteriosclerosis and eventually perhaps gangrene. The x ray has proved to be a very satisfactory method of diagnosing arteriosclerosis of the lower extremities and has yielded information of some value. Furthermore, the authors believe that the diagnosis of early arteriosclerosis of the lower extremities, which is difficult to make in any way but by x ray, is of considerable importance in the prognosis and management of vascular conditions, especially when combined with diabetes.

New Method of Treating Glycosuria.—Gustav Singer (*Wiener klinische Wochenschrift,* February 14, 1924), reports several cases of diabetes that were favorably influenced by parenteral injections of protein. Among these was one of an elderly woman, to whom an injection of milk was given for a serious complication of the eyes. The reduction of the excretion of sugar and the striking reduction in the blood sugar gave additional support to the author in his belief that the parenteral injection of proteins affects the metabolism of diabetics in a favorable manner. Among ten diabetic patients, five showed improvement after the parenteral injection of proteins.

Sixty-four Cases of Diabetis Mellitus Treated with Insulin.—Leon Jonas (*American Journal of the Medical Sciences,* November, 1923) says that thirty-four of the sixty-four patients did not gain weight; twenty-seven were two or more pounds heavier at discharge than their lowest weight in the hospital; two gained twenty pounds; four gained between ten and fifteen pounds; nine gained between five and ten pounds, and twelve gained between two and five pounds. His conclusion is that gain of weight is not immediate even on very liberal diets. Apparently an adjustment must take place before a gain in weight begins.

ENDOCRINOLOGY

Lugol's Solution in Exophthalmic Goitre.—A. S. Jackson (*International Journal of Medicine and Surgery,* April, 1924) presents a tabulated report on a series of twenty cases, and says:

In this series are reported twenty patients with a severe or moderately severe exophthalmic goitre; all received Lugol's solution and in all there was a remarkable clinical improvement. The administration of the solution was carefully gauged by a study of the basal metabolic rate by the Tissot gasometer method. As shown by the table, there has been an average reduction in the basal metabolic rate of eighteen per cent. The clinical improvement has been proportional. The patients no longer thrash about in bed and chafe their extremities; the staring expression so characteristic of their disease disappears, although exophthalmos persists until after thyroidectomy. The extreme nervousness accompanied by insomnia is abated, the patients are more quiet, and their demeanor is more composed. Apparently the greater the toxicity, the greater the degree of clinical improvement. Results in the treatment of toxic adenoma with Lugol's solution have not been satisfactory and its administration to these patients is not advised.

Simplified Treatment of the Goitre Question.—T. L. Deaver (*International Journal of Medicine and Surgery,* April, 1924) discusses the origin and distribution of goitres, the forms of enlarged thyroid, peculiarities of the thyroid, diagnosis, and treatment, in the light of his twelve years' experience. Among the most interesting of his observations are the following:

The thyroid gland is a necessary element in the work of internal secretion, and is closely related to the reproductive organs. Our records show a number of cases in which a large colloid goitre completely disappeared after hysterectomy for fibroids. Some ovarian tissue was left in each instance. Our custom now is never to remove a simple goitre when doing a hysterectomy. We have never yet encountered the combination of goitre and infantile uterus in the same patient. Because of its equalizing influence upon the other glands of internal secretion, the thyroid should never be removed during adolescence, except for unavoidable reasons.

The important features in the matter of diagnosis, we believe, are to determine whether a patient has a goitre or not; whether it is simple or toxic; and whether it is medical or surgical or both. The finer delineations between the toxic and nontoxic adenoma, and the toxic and exophthalmic goitre are scientific as well as therapeutic, but belong largely to the realm of treatment.

Concerning treatment the author says:

Electricity, violet ray and all forms of massage are of questionable utility. They may even do harm. X ray exposure in toxic and exophthalmic cases, before thyroidectomy, has many advocates. It appears to raise the patient's resistance to postoperative toxemia. Very little benefit is to be derived from such treatment in simple goitre.

To know when to operate and how to control hemorrhage are two great essentials in goitre surgery. And further, we need only say that, up to the present moment, no method or appliance has been devised by which the cardiac reserve can be absolutely determined. Sudden calamities in unsuspected instances, even when the metabolic rate and other findings were favorable, lend weight to this statement.

We should cease talking about bloodless tonsillectomy and work toward bloodless thyroidectomy. Control of hemorrhage is a life saving element in thyroid surgery. A quick operation, attended by excessive loss of blood, is much more shock to the patient than a bloodless procedure covering twice as much time. That the thyroid is closely connected with the sympathetic nervous system, is shown by intermittent dilatation of the pupil from traction on the gland. A very slow pulse during operation—sixty or below—is a danger signal, and indicates a weak myocardium. One should also take warning from a rapidly rising pulse rate, with a noticeable decrease in volume. A fall in blood pressure precedes this condition.

The preparation of the patient is of the utmost importance, and in exophthalmic cases may take weeks or months of time. It includes rest of body and mind, proper medicines, a selected diet, refreshing sleep and the free ingestion of water, especially during the last few days preceding the operation. Relatives and solicitous friends should be held in abeyance. While there is marked cerebral excitability with tachycardia, the room should be kept dark, sedatives given and ice applied to the precordium, the forehead and back of the neck. These patients cannot stand heat, and the mortality, operative and nonoperative, is apt to be higher during July and August.

Anent operative treatment Dr. Deaver says:

If it is possible to do a primary ligation of the polar vessels before removing the mass, much time and anxiety may be saved.

Traction on the windpipe and the pneumogastric, particularly in elderly people, should be strenuously avoided.

The recurrent laryngeal nerve and the parathyroids are protected in three ways: By avoidance of undue traction and rough handling of tissue; careful use of clamp and ligature deeply and about the inferior thyroid vessels, more especially the left; and by leaving the posterior aspect of each lateral lobe.

Of great importance is the fact that, after partial thyroidectomy for any form of goitre, stress being laid upon the toxic variety, the patient shows less resistance to intercurrent disease, rheumatism, pneumonia, acute endocarditis, tuberculosis, and so on. This apparent reduction of immunity may cover a considerable length of time. In our followup review of several hundred cases, operated on from two to twelve years, a study of the fatalities and their cause would seem to show that the thyroid gland may be a vital part in the chain of defense against disease.

X Ray Therapy in Exophthalmic Goitre.—Jose Gutierrez (*La Semana Medica,* April 3, 1924), writes that radiotherapy (not ultrapenetrating), cures hyperthyroidism whether pure or associated (Basedow's disease or cystic goitre). It alleviates both the goitre and the exophthalmos but does not cure them. It is a painless treatment and convenient as it necessitates merely a monthly session of short duration. It in no way contraindicates other treatments and the number of applications required is between ten and fifteen.

Medicolegal Notes.

NEGLIGENCE IN TREATMENT OF SPIRAL FRACTURE OF TIBIA NOT SHOWN.

In an action for malpractice in the treatment of a spiral fracture of the tibia, the testimony showed that the leg as set had good alignment, though the ends of the bone were not in full apposition. The Washington Supreme Court holds, Kemp v. McGillivray, 225 Pac. 631, that the defendant could not be successfully charged with malpractice, under the rule that a surgeon is not guilty of malpractice if the treatment he employs is that which is recognized and approved by those reasonably skilled in his profession, practising in the same neighborhood and in the same line of practice, and if he administers that treatment with such a degree of skill and diligence as such practitioners ordinarily exercise in like cases.

Medical witnesses all testified that the method of treatment used by the defendant—traction weights and pulleys—is recognized and approved by those skilled in the profession practising in that community and generally, and the most if not all of them testified that was practically the only method, and that, while the plaintiff was under the defendant's care, he was given that treatment with skill and diligence.

It was held not obligatory on the defendant to say anything to the patient early in the course of treatment about a probable shortening of the leg where he was not asked about it and he knew he was getting a good result, and this was not a willful concealment of negligence and lack of skill.

INSUFFICIENT EVIDENCE OF SURGEON'S NEGLIGENCE IN LEAVING GAUZE IN WOUND.

In an action for malpractice against the plaintiff's family physician and an operating surgeon, where it was claimed that defendants had negligently left a roll of gauze packing in the patient's body after an appendical operation, resulting in death, there was no claim of improper diagnosis by the family physician or negligence in procuring or recommending the services of the surgeon or want of care while present in the operating room. There was evidence that both hospital staff and surgeons exercised the highest possible degree of care at the time of the operation. It was held that the physician could not be held liable. "Standards of duty for a family physician attending an operation under circumstances appearing in this case cannot be established by argument or assertion. What constitutes ordinary care in a case such as this is to be determined by the testimony of those who know what it is, not as a matter of common knowledge."

The burden was held to be upon the plaintiff to satisfy the jury to a reasonable certainty that the pack was left in the body of the deceased by the surgeon. It is not sufficient for the evidence to raise a suspicion or to indicate a possibility. It must be sufficient to remove the controverted question from the field of doubt and speculation into that of reasonable certainty. Three years before the first of the two operations by the defendant in 1920 the patient had been operated upon for appendicitis and the evidence showed that such packs are ordinarily used in appendical operations or were at the time of the first operation, in 1917, in the place of operation. The court held that, upon the whole evidence, a finding that the pack was left in 1917 would have as much support as a finding that it was left in 1920, and as a verdict cannot rest upon mere speculation judgment for plaintiff was reversed.

CHIROPODY NOT A BRANCH OF MEDICINE OR SURGERY.

The Idaho Supreme Court holds, in the prosecution of a chiropodist for practising medicine without a license, State v. Armstrong, 225 Pac. 491, that under a reasonable interpretation chiropody does not involve the practice of medicine or surgery, either major or minor. Chiropody, however, has some relation to the public health and may be regulated by the Legislature. Such regulation must be reasonable, and must bear some relation to the object sought to be attained, which is to protect the public from being mistreated or misled by incompetent or unscrupulous practitioners. To require a chiropodist to obtain the education and license of a physician and surgeon, an osteopathist or a chiropractor, is held not to be a reasonable regulation, and utterly unnecessary for the protection of the public.

Idaho, Sess. Laws 1923, provides that it shall be unlawful for one to treat any physical condition of any person for a fee. It is held that the general language used in the cat would make it apply to chiropody, and in so far as it does affect the practice of chiropody, the act is unconstitutional and void.

The acts charged against the defendant were the removal of corns and callouses and the treatment of a Morton toe by binding and strapping the foot. The court was of opinion that the former constituted chiropody, but was not so sure about the latter. If that fell within the scope of medicine and surgery, the defendant would be guilty. The stipulated facts did not make possible an intelligent answer to this question, and judgment of conviction was reversed for a new trial.

BREAKING OF NEEDLE DURING REMOVAL OF TONSILS.

In an action for alleged malpractice in the removal of plaintiff's tonsils, during which a hypodermic needle broke, the first specification of negligence, that the doctor should have used a general anaesthetic and not a local one, was held negatived by expert testimony that the general practice is to use a local anaesthetic instead of a general one, in removing tonsils from an adult.

The second specification of negligence was that the defendant should have known of the breaking of the needle and at once informed plaintiff. Defendant testified that he did know, but judged it proper not to inform plaintiff until she had an opportunity to recuperate through rest and sleep.

On discovering that the needle had broken, defendant's efforts to extract it failed and he decided to proceed with the operation. It was held that the correctness of his judgment was subsequently shown by the fact that the part of the needle which had broken off could not be found in the tissues of plaintiff's neck without the aid of X-ray plates, and after its position had been ascertained the efforts to remove it were not successful.

Malpractice was held not shown by the fact that the needle broke, or that part of it remained in plaintiff's body.—Mandelbaum v. Weil, 208 N. Y. App. Div., 409, 203 N. Y. Supp., 289.

TYPHOID FEVER NOT ARISING OUT OF EMPLOYMENT.

The Michigan Supreme Court holds, Ames v. Lake Independence Lumber Co., 197 N. W. 499, that the contraction of typhoid fever is an industrial accident within the State Workmen's Compensation Act, but contracting typhoid fever by drinking water from a pipe at some distance from the place of employment without the knowledge of defendant, the owner of the premises on which work was being done by the plaintiff's employer, an independent contractor, was not an industrial accident caused by exposure to some special hazard incidental to or arising out of his employment; and an award of compensation was set aside.

Trustworthy!

The extent to which innumerable practitioners of medicine are today employing

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

whenever a dependable reconstructive tonic is called for, tells in no uncertain way of its therapeutic utility and gratifying efficiency.

During the thirty-five years this reliable tonic has been at the service of the profession, the quality of its ingredients and the unvarying character of the composite product have been consistently and faithfully maintained.

Thus it is easy to understand why the host of medical men who have learned how reliable it is in its character and results, not only take pains to order the original Gray's Glycerine Tonic Comp. (P. F. Co.), but also to see that their patients get no other!

Such care is well worth while, for it often measures the difference between success and failure.

The Purdue Frederick Co., 135 Christopher St., New York

Valentine's Meat-Juice

In **Typhoid, Gastric** and **Other Fevers,** where it is **Essential** to **Sustain** the **Patient** without **Irritating** the **Weakened Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening** when **Other Food Fails.**

J. R. Wood, M. D., *Physician Sheltering Arms Hospital, Paint Creek, W. Va., U. S. A.:* "I have been using VALENTINE'S MEAT-JUICE in the treatment of Typhoid Fever cases in the Sheltering Arms Hospital, for the last two or three weeks, with the most gratifying results both to the patient and physician. I consider it the best preparation of animal food I have ever seen, in fact, the only one I have ever had any success with."

Dr. Genevaix, *Assistant Surgeon-Major, First Class, Hotel Dieu, Creusot, France:* "The patients to whom I have given the excellent preparation, VALENTINE'S MEAT-JUICE, have found their general condition rapidly improved by it, and in the convalescence from continued Fever (Typhoid and Para-Typhoid) it gives the best results."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

PREPARATION
NUTRIO PERVIE
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS–Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Contribution for a Marine Hospital at Bath, Me.—In 1878 a grateful patient or friend of the Marine Hospital Service (now the Public Health Service) donated $523.50 "for the benefit of the Marine Hospital at Bath, Maine." The amount was placed at interest by the Collector of Customs, and is still on deposit, because there was no Marine Hospital at Bath, Maine, and never has been, the nearest ones on that coast being located at Portland, Maine, and Boston, Massachusetts. Practically all cities in the United States are increasing in size, and the city of Bath is no exception to this rule. It is not at all improbable that the time may come when a new Marine Hospital will be needed on the Maine Coast to serve those who go down to the sea in ships, in conformity with the Government policy established in 1798 to provide medical care for merchant seamen. Students of compound interest may compute the period necessary for the donation to grow to the necessary amount.

Vaccination Two Thousand Years Old.—Vaccination is an outgrowth of man's effort to protect himself from pestilence by using nature's methods of defense. Primitive man noticed that recovery from a first attack by most diseases gave immunity against other attacks; and, some two thousand years ago, he began to inoculate his fellows with smallpox when conditions seemed propitious instead of waiting for nature to do it at some time when conditions might be very unpropitious. Inoculations against smallpox were made in India and in China as early as 300 B.C. Later, when the disease reached Europe, inoculation went with it, supplemented by a new method called "selling smallpox"—exposing a well person to contact with one ill with the disease so that, if he survived, he would be proof against it. . . . Before the days of vaccination, conservative estimates show that one third of all persons had smallpox and one tenth of all deaths were due to it. . . . Formerly, smallpox was considered a children's disease; and it still is a child's disease—where infantile and school vaccination are neglected. —*Dr. G. W. McCoy.*

The Smallpox Peril.—The history of smallpox shows conclusively that there is an ever present danger to the unvaccinated community, and in modern times this danger is intensified by the increased and rapid communication between towns and cities, says the Connecticut State Department of Health. Indeed, so rapid has travel become that a person infected with smallpox can travel almost half way around the world before the incubation period of the disease has expired. It is common in this country to find persons suffering with smallpox who received their infection in Canada, Mexico, Portugal, Sweden and other European and South American countries. The danger zone for us therefore, is any point in the world which can be reached or from which persons can arrive in from fourteen to twenty-one days, this being the period between the infection by smallpox and the appearance of the symptoms of the disease.

In Fitchburg, Massachusetts, in 1918, smallpox was imported from Canada; in New Bedford in 1919, from Portugal; and the epidemic in Worcester in 1917 which resulted in 48 cases and 10 deaths, originated in Finland. This latter invasion was particularly interesting for the reason that passengers from the ship carrying the Worcester infection were also responsible for outbreaks in New York, Minnesota and several other states.

Foreign ports are not by any means responsible for all the original infection in this country; in Connecticut in 1921 outbreaks occurred which were due to infected individuals coming from North Dakota, New York, South Carolina, Illinois and Rhode Island; and in 1924, the outbreak was due to infection from Canada.

It is fortunate that most of the outbreaks of smallpox in this country have of late years been of the mild type with relatively few deaths, but malignant smallpox with high mortality is ever present in Mexico and some of the European countries and this malignant type may at any time appear among us. Malignant smallpox is particularly liable to occur in communities where vaccination has been long neglected and where epidemics are allowed to run uncontrolled. The type of smallpox in Connecticut in 1924, one in eight being fatal, is more fatal than for twenty-five years in the state.

Diseases Under Investigation at the Hospital of the Rockefeller Institute.—The following conditions are being studied in the Hospital of the Rockefeller Institute for Medical Research; patients suffering from these diseases will be admitted to the extent of the hospital facilities:

1. Chickenpox: Either children or adults with chickenpox will be admitted to the Isolation Ward of the Hospital; it is desired that they be referred early in the disease.

2. Nephritis: Patients suffering from acute nephritis or from moderately severe or severe chronic nephritis. Young persons with these diseases, particularly those with edema, are especially suitable.

3. Rheumatic fever: Patients should be referred early in the course of the disease, preferably before receiving antirheumatic drugs. Those suffering from one or more of the following manifestations are desired: acute rheumatic polyarthritis; subcutaneous rheumatic nodules; chorea accompanied by polyarthritis or subcutaneous nodules; rheumatic carditis accompanied by polyarthritis or subcutaneous nodules.

4. Acute pulmonary infections, including acute lobar pneumonia: It is desired to receive patients suffering from atypical forms of acute infection of the respiratory tract as well as patients with acute lobar pneumonia. Patients with the latter condition should be referred as early in the disease as possible. A chamber is available in which patients suffering from severe cyanosis may be treated in an atmosphere rich in oxygen.

5. Cardiac disease: In continuing the study of the treatment of chronic heart disease, it is planned to admit patients, either young or old, in the more advanced stages of heart failure. Those having completely irregular pulse and fibrillation of the auricles are especially desired.

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

Literature on Request

Schieffelin & Co.
NEW YORK

IN CHRONIC CONSTIPATION

the bowel contents are abnormally retained in the intestinal canal. As a result, over-digestion takes place, with over-absorption of fluids from the fecal mass, leaving them hardened and reduced in bulk. In this condition the bowel contents, failing to provide the normal stimulus to the intestinal muscles, are still further delayed in their passage, thus preventing the elimination of toxic wastes.

In AGAROL COMP.—a palatable preparation of pure mineral oil, agar-agar and phenolphthalein—the practitioner has at his service a true bowel corrective. Administered in proper doses, it mixes thoroughly with the feces, making them soft, plastic and increased in bulk. In this condition they furnish the natural stimulus to peristalsis, and this, with their incidental lubrication, assures their ready passage.

Used over a reasonable period, therefore, Agarol Comp. restores the muscular tone and functional activity of the bowel, with the gratifying assurance that natural evacuations will follow regularly without the need for any further medication.

AGAROL is the *original* Mineral Oil-Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbances—Not habit forming.

Fur Dermatitis.—The report of an inquiry into the causes of fur dermatitis by Dr. Allan C. Parsons has just been issued. From a study of the literature it appears that nothing was published until 1909, and although isolated instances had been seen by dermatologists from time to time, there is no history of any aggregation of cases previous to the winter of 1922-23. Early in the latter year, Dr. J. H. Sequeira, of the London Hospital, informed the Ministry of the existence of several cases, and it was due to his initiative that it was decided to pursue further inquiries into this subject. In March, 1903, Dr. H. C. Semon, of the Royal Northern Hospital, and Dr. A. C. Roxburgh, of St. Bartholomew's, contributed papers to the medical press giving clinical details of fur dermatitis which then for the first time began to attract public attention.

It is no new experience to come across persons who are unable to wear any sort of fur without discomfort, and various chemical preservatives against moths had long been recognized as capable of producing irritation of the skin. But the sudden increase in the number of cases pointed to some new method of preparing or dyeing the skins, and the widespread nature of the socalled epidemic, suggested some common factor.

Fashions in furs change from year to year, but since the war there has been a great increase in the use of cheap varieties, and to meet the demand substitution products have been supplied. The pelt of these comes from the rabbit and is dyed to resemble beaver, the finished product being known as beaver-coney; and almost without exception this has proved to be the fur used by those who have developed dermatitis. One Manchester firm alone is said to have sold nearly twenty thousand coats, with collars of this material, in two months.

On developing the inquiry it was shown that the personal idiosyncrasy is not the paramount factor, and that the use of arsenic in the preparation of the pelt is very unlikely to be the cause; and attention was concentrated upon the dyeing of the fur, which in the end was held to be the responsible agent in the production of irritation.

But even now it is difficult to indicate with certainty the exact dye developer used in any individual case, though the Fur Trade Association and their technical advisers were unanmious in thinking that paraphenylenediamine was the agent employed in dyeing the furs complained of. And the more so since this, when used as a human hair dye, has been frequently known to produce similar symptoms.

On the other hand one analyst considered that metaphenylenediamine, an isomer of the above, which is now constantly used in the dyeing industry, was the irritant in question. These two divide between them the responsibility for producing fur dermatitis. The skin being immersed in a bath of the developer, the dye is developed by oxidation with hydrogen peroxide, the first oxidation product, whose chemical identity is undetermined, being actively irritant. The result of the inquiry shows that so long as the oxidation is complete—which ever agent be employed—the dyed article is innocuous; and that the cause of the trouble lies in defective or careless technic in the use of potentially dangerous dyes, and not in the skins themselves.—*Medical Press,* September 24, 1924.

Upper Abdominal Postoperative Infection

HOWARD M. CLUTE, M.D.,
Boston.

The occurrence of suppuration in the upper abdomen following trauma or operation is not infrequent, but the recognition of this condition is often long delayed or completely overlooked.

Since the publication of a recent paper on subphrenic abscess (1), I have operated upon four further cases of this type and two others have been seen. Obviously the condition is not rare and more attention should be given to the possibility of subphrenic or subhepatic infection in cases which are not doing well after operation.

Subphrenic abscess is not a disease which always presents outstanding diagnostic features. We find that with our increasing familiarity with this lesion we now suspect it until we prove it is not present in cases which do badly after operation. We are certain that in Case VII we would not have made a diagnosis had we not persisted in directing our efforts distinctly toward proving the presence or absence of a subphrenic abscess.

In common with other surgeons, we have found that when a continued fever develops in a postoperative case the trouble lies, ninety per cent. of the time in the wound of operation. Continued fever after an abdominal operation means that we must disprove the presence of the following things: 1, wound infection either superficial or deep; 2, abscess formation in the pouch of Douglas; and 3, subphrenic infection.

Abstracts of the histories of nine patients who showed evidence of the last named cause of postoperative fever are presented. Seven of these patients had suphrenic abscess. One showed a bile peritonitis following cholecystectomy and one presented multiple abscesses of the liver.

CASE REPORTS

CASE I.—A. P. Bullet wound of abdomen. Wound of entrance over xiphoid process; wound of exit over right posterior iliac spine. No symptoms of any sort until several weeks after the injury. Patient then began having daily fever which increased in severity and persisted. Some fullness and lack of mobility of the right chest. Pain with deep (fist) percussion. Marked loss of weight and strength. X ray showed right diaphragm high and fixed. Needle puncture revealed pus. Operation; two stage drainage. Recovery.

CASE II.—Mrs. L. Operated upon for perforating appendicitis with diffuse peritonitis. Appendectomy with abdominal drainage and an enterostomy were performed. Ten days after operation patient began having fever which persisted. Toxic psychosis developed. Abdomen showed some fullness in the upper right quadrant. Some edema over the skin posteriorly. Rectal and vaginal examination negative. X rays showed high fixed diaphragm on the right with a clear costophrenic angle and a definite gas bubble with fluid line below the diaphragm. This abscess was drained by the two stage method. Recovery.

CASE III.—Mrs. M. Operated upon for a ruptured appendix with diffuse peritonitis. Four days after operation persistent fever developed with no abdominal signs save tenderness in the right upper quadrant. Later some bulging just below lower ribs in the midaxillary line. A large subphrenic abscess was incised below the rib margin in the right axillary line. Recovery.

CASE IV.—Mr. B. A. Operated upon for large pyloric ulcer. A Polya operation was performed. Ten days later rise in temperature developed. This varied daily between 97.6° and 103 or 104°. He had no abdominal signs save some fullness over the right upper abdomen and deep tenderness. There were some râles over the right base with bronchovesicular breath sounds. A large subhepatic abscess lying along the right lateral colic groove was incised below the rib margin in right midaxillary line. Recovery.

CASE V.—Mrs. W. Operated upon at another hospital for acute cholecystitis with gallstones. A cholecystectomy was performed. On the third day after operation the drain was removed. A few days later fever began which persisted. Examination was entirely negative save for dullness over the base of the right lung. Deep tenderness over the liver anteriorly with some fullness of the upper right abdomen. X rays showed a high fixed right diaphragm. A large subphrenic abscess was drained by the two stage operation. Recovery.

CASE VI.—Mrs. W. E. L. A cholecystectomy was performed on this patient and a badly infected gallbladder full of stones was removed. Recovery was uneventful until the sixth day after operation, when her temperature began to rise. On the twenty-first

Copyright, 1924, by A. R. Elliott Publishing Company.

day after operation she had a fever of 103.6°. She presented some tenderness in the right flank and some deep tenderness over the liver. X rays showed a high fixed right diaphragm. Hot poultices were applied over the right upper abdomen and a probe inserted into the drainage track remaining from the cholecstectomy. In a few days much purulent discharge came from the wound and the excessive temperature cleared up. Later x rays showed improvement in the relative position of the diaphragm with a final return to normal. This was undoubtedly a beginning subphrenic abscess which was drained through the original drainage tract and cleared up. At the time this patient was in hospital we took x rays of the diaphragm of several patients who had recently had a cholecystectomy. In no case was the diaphragm either high or fixed in its motion.

Case VII.—Mr. B. This man fell three feet and struck his right loin against the point of a pickaxe. He sustained a small wound in the right midaxillary line, just above the iliac crest, which healed in a short time. Ten days later there developed a moderate rise in temperature which rapidly grew more severe. In the hospital he showed no abdominal symptoms, but closely resembled an empyema. His temperature ranged from 104° to 105° and his respirations were 35 to 40. He presented well marked dullness over his right base with bronchial breath sounds just above. The heart was pushed well over to the left. There was some fullness over the right upper abdomen with deep tenderness on fist percussion. Repeated x rays were indistinct and no definite elevation of the diaphragm could be seen because of the general haziness over the right chest. Two chest taps were done, with negative results. A needle was then inserted on a later date between the ninth and tenth ribs in the midaxillary line on the right because we felt sure subphrenic abscess was the most reasonable diagnosis. At a depth of four and one third inches, pus was obtained. A large subphrenic abscess was drained by the two stage operation. Some days after the second operation the patient had a severe coughing spell and spat up several ounces of thick odorless pus. He continued to cough up this pus for some days. X ray of his chest showed no new pathology. He soon improved and ultimately made an excellent and complete recovery.

Case VIII.—Miss W. Three weeks prior to admission a cholecystectomy was performed in another city. The drain was removed a few days later and after two weeks the patient returned to her home. One week ago rise in temperature developed which persisted. Examination showed a very sick, emaciated girl with a high fever. Some abdominal fullness. Tenderness especially over the lower border of the liver, edema over the right loin posteriorly. We believed this girl had a subphrenic abscess following her cholecystectomy. X rays, however, showed a normal diaphragm on each side as to height and excursion. A small incision was made over the right lateral abdomen below the rib margin. Several large pockets of cloudy bile were found and drained. A catheter was sewed into a piece of distended gut and the belly closed. This girl had a bile peritonitis largely localized to the right upper abdomen but below the liver. She died after her second operation.

Case IX.—Mr. L. A man of forty-eight who had been sick with persistent irregular fever for three months. Recently he had spent several weeks in another hospital, where every method of examination, including an exploratory laparotomy, had been made use of without reaching a diagnosis. In this case no known cause for a possible subphrenic abscess could be found. X rays of the chest, however, showed that the diaphragm was markedly elevated and fixed on each side. There was some fullness and restricted motion in the right upper quadrant with tenderness to deep percussion. Needle puncture in the right midaxillary line in the ninth space gave foulsmelling pus. Under local anesthesia the first stage of a drainage operation was performed. Thirty-six hours later the patient became deeply jaundiced, had several chills and passed away in about eight hours.

Autopsy showed multiple abscesses of the liver varying in size from a very minute focus to cavities 1.5 cm. in diameter. No etiological factor could be found.

The outstanding point in every case which led us to consider the possibility of a subphrenic abscess was the history of an abdominal injury or operation and subsequent continued fever not readily explained. Because of this, we admit to having looked for a subphrenic abscess many times in vain. On the other hand, we believe we have not overlooked one in recent years.

In Case VII there was a wound of the right loin with a pickaxe. The wound healed and the patient did well for two weeks, when he developed a daily fever that grew steadily worse. In Case V a cholecystectomy had been performed and the drainage removed on the third day. A week later persistent fever developed with mild abdominal distention. In Cases II and III a gangrenous appendix had been removed with improvement for a time. Later fever and marked prostration developed with no remarkable abdominal or rectal signs. In two cases we had bullet wounds of the upper abdomen followed by fever of long duration. Case IV was a resection of the pylorus with excellent recovery for fourteen days, when fever developed with some upper abdominal fullness and tenderness. Thus in every instance in this series there is a history of preceding trauma which becomes of great importance when later complications arise.

The second important feature in all these cases has been the lack of localizing symptoms recognized by the patient. In some cases there has been a sense of epigastric fullness. In one instance there was some pain with deep breathing.

Every case has had well marked fever which, in general, has been of the picket fence type with a wide daily range of temperature. Loss of weight and strength have been unusually marked in every patient whose illness was at all prolonged. Neither diarrhea nor constipation has been a feature of any case. Vomiting has not occurred in this series.

The physical signs present in these patients have been quite constant. Most noticeable has been the limitation of motion of the right chest with respiration. At the base of the right lung there has been some dullness due to the presence of sterile fluid in the pleural cavity and to the compression of the lung

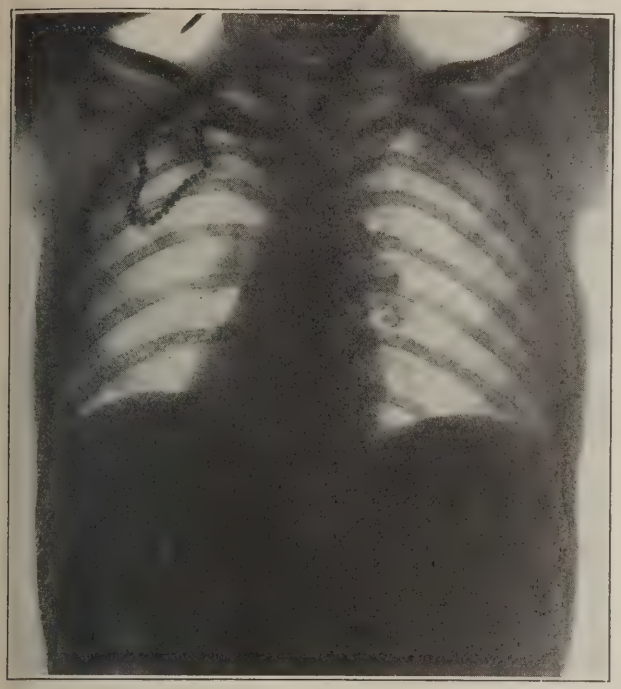

FIG. 1.—Case VIII. Bile peritonitis after cholecystectomy. Subphrenic abscess was ruled out in this case by the normal relative position of the right and left sides of the diaphragm.

by the high diaphragm. Pain on deep percussion or "fist percussion" (Murphy) has been very constant and we consider this a very important sign when it is present. Edema of the subcutaneous tissue over the right lower back has occurred twice. We have once seen the apex of the heart pushed well over to the left by a moderate sized subphrenic abscess on the right (Case VII). It returned to its normal position after drainage of the abscess.

We consider a typical x ray picture of the greatest value in making a diagnosis of subphrenic abscess. The diaphragm of the affected side will be found high, smoothly rounded and fixed. Its normal excursion of two or three inches will be reduced to a quarter of an inch. The costophrenic angle will generally be clear, but this picture may be clouded by accompanying fluid or bronchitis in the right chest. In a few cases a gas bubble will appear just under the diaphragm with a straight line fluid level below when the patient is in the sitting position. This has occurred in but one case in this series.

In Case IX we found the diaphragm high and fixed on both sides. This was not consistent with a subphrenic abscess, but when considered with the clinical symptoms it did point to pathology below the diaphragm on each side. The finding of multiple abscesses in each lobe of the liver at autopsy confirmed this belief. In Case VIII we found many clinical symptoms which made us believe a subphrenic abscess was present. The history of a cholecystectomy three weeks before; of irregular fever beginning after two weeks of normal postoperative convalescence; the presence of fullness and deep tenderness in the upper right quadrant; and edema of the superficial tissues over the right loin were all consistent with a subphrenic abscess on the right side. An x ray, however, showed both the right and left side of the diaphragm at a normal level. This ruled out the presence of a pathological condition in the immediate neighborhood of the diaphragm.

It is, of course, well known that the diaphragm is occasionally found high and fixed with a rounded domelike surface on one side when no abdominal pathology can be demonstrated. We have seen one such picture in a chest x ray taken to determine the presence of an intrathoracic goitre and we were unable to discover any clinical symptoms referable to it. Paralysis of one side of the diaphragm with consequent elevation and lack of mobility is seen very rarely by the x ray men. It may be congenital in origin or it may arise from a precedent disease or injury of one phrenic nerve. This lesion offers little difficulty in the diagnosis of subphrenic abscess because of its rare occurrence and the lack of accompanying symptoms.

When the history and physical findings point to the diagnosis of subphrenic abscess but are not conclusive, we resort to an exploratory puncture with a long needle. We have made such a puncture in four cases in the midaxillary line at the eighth or ninth space to confirm our belief when other measures were insufficient for making a diagnosis. We believe that tapping in this location should be done with great care and only when other positive diagnostic signs fail. We have seen no ill effects from it.

We use a lumbar puncture needle with a syringe attached. Under novocaine anesthesia, the needle is inserted in either the ninth or tenth space in the right midaxillary line. Usually the pus will be found at a depth of two inches or less in thin patients, though it may be advisable to push the needle farther in if reasonably certain that pus is present. In Case II we obtained foul smelling gas and only a little pus with aspiration. If the puncture is made at a level higher than the ninth space, the needle may pass through the pleural cavity at a point where the parie-

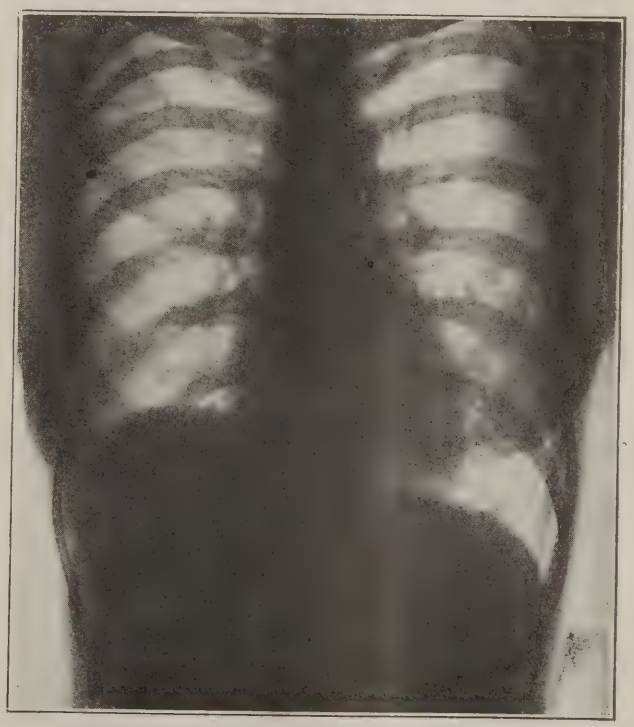

FIG. 2.—Case IX. Right subphrenic abscess. Note high, fixed diaphragm on the right with evenly rounded dome and clear costophrenic angle.

tal and visceral pleura are not in contact. Clear serous fluid from the chest cavity may thus be obtained on aspiration followed by pus as the needle passes through the diaphragm. This occurred in Case I. Infection of the pleural exudate may well follow this procedure. If serous fluid is obtained with tapping, therefore, the needle should be withdrawn and inserted in the next lowest interspace.

Recovery from infection in the subphrenic space demands, 1, the establishment of early and wide dependent drainage, and 2, the prevention of infection of the adjacent serous cavities with consequent empyema or peritonitis. In two cases in this series a palpable tender mass presented in the anterior axillary line just below the costal margin. In such a case an incision should be made below and parallel to the last rib over the mass and the abscess carefully drained. The general peritoneal cavity in such a case is not liable to contamination. In all the remaining cases of subphrenic abscess we have found the two stage operation described in our previous paper entirely satisfactory. In the first stage two or three inches of the right ninth or tenth rib in the posterior axillary line is removed. The parietal pleura is opened and sutured to the diaphragm. The wound is packed with sterile gauze and left for forty-eight hours. This walls off the pleural cavity. In the second stage of the operation, the diaphragm is incised through this wound and the abscess cavity drained with a rubber tube.

Neither empyema nor peritonitis has occurred in this series of cases of subphrenic abscess. All patients made excellent recoveries.

The Pineal Gland and Its Function

JAMES H. HUTTON, M.D.,
Chicago, Ill.

This peculiar gland lies between the anterior quadrigeminate bodies, just above the sylvian aqueduct and weighs about 0.2 gram. It is largest in the early years of life and undergoes retrogressive changes after puberty. Microscopally it consists of epithelial cells arranged loosely in trabeculæ with long sinuslike capillaries between them. Neuroglia and sometimes muscular fibres are also present. Curious globules of calcareous material (brain sand) are also found in it. This is especially true in the pineal of man. Contrary to the statements recently seen in the lay press it does not calcify at thirty, or, for that matter, at any other age. The same calcareous changes that occur in the arterial walls seem to occur in the pineal. In later life these sometimes become sufficient for the pineal to cast a shadow in x ray films of the skull. That this is only an occasional occurrence is shown by the fact that few of us have ever seen such a shadow while all of us have seen a great many x ray pictures of the head. It is developed from the evagination of the third ventricle and is homologous with the socalled reptilian mideye.

Most investigators, clinicians and experimental physiologists alike, agree that the pineal is a gland of internal secretion, that it has some relation to the other endocrine glands, and that its sphere of influence is exerted on the body and sexual growth. The exact nature of this influence, whether inhibiting or stimulating, is a question which is not agreed on. One group of observers believes that the gland produces a secretion which inhibits the growth of the body and restrains mental and sexual development from exceeding the rate accepted as normal for preadult life, while the other group holds that this secretion has a stimulating effect in the same sphere.

Our scant knowledge of its function has been obtained in three ways. First, by removing it in young animals and ascribing the changes that follow this operation to lack of function of the pineal. Second, by noting the train of symptoms that occur in the presence of tumors of the gland in children. Third, by feeding experiments, the dried gland being fed to animals both laboratory and human.

Extirpation experiments. In most cases where the gland has been successfully removed it has been found that the body growth is stimulated and that the sexual characteristics develop more quickly than in the normal controls. The work of Dandy of Baltimore does not agree with this. He devised a new approach to the pineal involving a minimal amount of brain trauma. He removed the gland from puppies and kept them in apparently perfect health for months afterward. Neither the clinical history nor the autopsy disclosed any evidence that complete extirpation of the pineal had any effect on puppies.

SYMPTOMS ACCOMPANYING TUMORS OF THE PINEAL

It is an interesting fact that tumors occur much more frequently in boys than in girls and that they usually occur before the age of fourteen. Teratoma, which is a rather rare tumor form in any location, makes up twenty-five per cent. or more of all tumors of the pineal. There is a rapid body growth so that a child of six or seven years may have the appearance of a child near puberty. A precocious growth of pubic and general body hair, enlarged genitalia, early sexual development and early change in voice. Precocious mental development manifested by a maturity of thought and speech. Besides these things that are peculiar to pineal tumors there are the usual signs of increased intracranial pressure and the symptoms due to pressure on surrounding structures of the brain.

One group of observers have attributed the symptoms in the case of tumors to a deficient function of the pineal, it being assumed that the tumor destroys the pineal tissue and that the accompanying metabolic and neurological disturbances occur as a result of lack of pineal secretion. Another group of observers hold the opposite view, that the tumor causes an increased amount of pineal secretion to be produced and that the symptoms are due to a hyperfunction of the gland. Dana and McCord especially hold this view. Knud Krabbe believes that we may recognize a clinical picture in which pubertas precox coincides with teratoma formation in the pineal. Thus we may be permitted in a number of brain tumors in children to diagnosticate with great certainty that the tumor is a teratoma of the pineal. Krabbe expresses no opinion as to whether the tumor causes an increase or decrease in the amount of pineal secretion.

Feeding of pineal has been done on a considerable scale by Berkeley. He claims accelerated somatic growth in kittens, rabbits and guinea pigs, while a number of backward children to whom the gland preparation was administered for sufficient periods of time made an advance in mental age considerably in excess of any previous progress for a like period. The fresh glands of young bullocks were rapidly dried, mixed with milk sugar and put up in capsules, each capsule corresponding to one hundred and fifty pounds of bullock live weight. The ordinary dose for a child weighing twenty-five to fifty pounds was two capsules a day. He also found that when the pineal gland was fed to babies it caused an increase in the metabolic activity as evidenced by an increase in the nitrogen in the urine.

It is reported by others that the administration of pineal substance to young mammals hastens growth and sexual maturity.

Following are some of the theories that have been advanced regarding the function of the gland. Dana and Berkeley believe that the pineal furnishes a ferment or catalytic agent which facilitates the exchange of nutrient material by the brain cells.

DeLyon advances the idea that the gland has a mechanical function regulating the inflow and outflow of the cerebrospinal fluid from the third ventricle. While this theory has not been substantiated the finding of striped muscle fibres in the pineal of cattle attaches some significance to it.

Cushing and most others believe there is a definite relation between the pineal and the sex glands; but do not agree as to what this relationship is. McCord and Allen state that the pigment cells (melanophores) of tadpoles become contracted after pineal feeding. As the receptors of the reflex governing such reactions of various animals are situated in the retina these investigators give significance to their observations by correlating them with the fact that the pineal is the homologue of the reptilian mideye.

McCord states that the essentials of pineal pathology are as follows: 1, early sexual development, enlarged genitalia, precocious growth of pubic and general body hair and early change in voice; 2, precocious mental development manifested by a maturity of thought and action; 3, general overgrowth of the body to the extent that a child of six or seven years may have the appearance of a child near puberty. Timme believes that disturbances of the pineal play an important part in the pathology of progressive muscular dystrophy.

It is not difficult to differentiate a pineal disturbance from an overactivity of the pituitary especially the anterior lobe which it would most closely resemble. The pituitary overactivity leads to an over development of the body but it does not manifest itself, as a rule, as early as the pineal disturbance. There is no early maturity of the sexual apparatus and no precocious development of the body or pubic hair or of the mentality.

The author's experience with this gland has been limited entirely to the administration of the dried gland to underdeveloped children. The results so far have been nil. My feeling at this time is that our knowledge is so limited and the views regarding its function so conflicting that it has very little interest for the average practitioner. Our knowledge at this time would permit us to recognize certain rare brain tumors in children as being teratoma of the pineal. Such an opportunity would hardly occur more than once in the life of the average man.

So far as we know it does not calcify at thirty or any other age. There is little or no evidence to support the statement recently appearing in the lay press that it has anything to do with regulating either judgment or emotion or their interplay. Neither is there any evidence that pineal pathology has any relation to criminal tendencies in either the young or the old.

Outdoor Sleeping in Winter for the Sick and the Well

S. ADOLPHUS KNOPF, M.D.,
New York.

The fall campaign number of the Bulletin of the National Tuberculosis Association contains a most interesting news item. It is printed under the title, National Tuberculosis Association Inaugurates Winter Outdoor Sleeping Campaign. Among other things it says, "While the campaign is for rich and poor alike it must of necessity be aimed at the well to do, for it is the latter who can best afford to sleep outdoors comfortably in cold weather."

If I did not know that the publicity director and all those connected with the publication of the Bulletin of the National Tuberculosis Association had the welfare of the masses at heart, I confess that the foregoing sentence would be rather depressing to me. To the uninformed it might seem that the association cares less for the welfare of the poor than for the rich, but having been associated with this society and its activities from its very inception, I can vouch for the contrary. The officers and members of the association, knowing only too well that tuberculosis is a disease of the masses, have always been most eager to reach those in greatest need of their assistance, i. e., the poor and less well to do.

The statement has gone out in print, however, and no doubt has been copied and thousands have read it. This is why I desire, by the publication of this article in the widely read MEDICAL JOURNAL AND RECORD, to counteract whatever unfortunate effect has been caused by this statement. All connected with the National Tuberculosis Association, in any capacity whatsoever, know that the poor are just as much in need of outdoor sleeping as the well to do. In fact, the men or women who work all day in shop or factory do not get the best of air during working hours, and for them the better, purer, less dusty night air will prove as much a godsend as to the rich who can afford outdoor sleeping porches, verandas, or outdoor tents and other expensive and elaborate devices, such as electric heaters, costly woolen blankets, and other means.

I am happy to be in a position to suggest to physicians for their poorer patients and to the not "well to do" healthy individuals a method of outdoor sleeping without veranda, without balcony, without outdoor tent, or the like. It consists of my modest invention, the indoor window tent, of which I presented the first model to the medical and lay public in February, 1905, and the description of which appeared in the NEW YORK MEDICAL JOURNAL of March 4, 1905. The tent, the mechanism of which has been improved from time to time, is no longer a patented article. An ungrateful and unscrupulous assistant of mine had patented my tent for selfish purposes shortly after I had shown it to the profession in as nearly perfect a model as possible, at a meeting of the New York Academy of Medicine. This patent made the price for the simple device so high that it was impossible for poor patients to purchase the tent. My protest to the Commissioner of Patents that the device was my invention and that it was against all medical ethics to patent lifesaving devices, and that the tent was mainly intended for the consumptive poor living in tenement houses, was respectfully but regretfully considered. The patent had been taken out in legal form and granted before I was made aware of it. I am glad indeed to announce today that by a recent decision of the Commissioner of Patents, Department of the Interior, the patent has expired and that the device disclosed therein has become public property and may be manufactured and sold by any one.

Anybody who wishes to enjoy the outdoor open air at night can do so even if he has only one room. If he is handy with tools, or has a friend who possesses this accomplishment and is willing to help him, he can soon construct my window tent, simplifying or modifying it in any way, without fear of being prosecuted for infringing on patent rights. The following is a simple description of the device which can be constructed for a few dollars:

The window tent consists of an awning, which, instead of being placed outside of the window, is attached on the inside of the room. It is so constructed that the air from the room cannot enter or mix with the air in the tent. The sleeper lying in the bed, which is placed parallel with the window, has his head and shoulders resting in the tent (Figs. 1, 2 and 3). By following the description (Fig. 4) closely, it will be seen that the ventilation is as nearly perfect as can be produced in so simple a device. The tent is attached to the frame of an American window, but it does not quite fill the lower half. A space of about three inches is left for the escape of the warm air in the room. By lowering the window, this space can be reduced to one inch or less, according to need. On extremely cold and windy nights there need not be left any open space at all above the tent frame. The sleeper's breath will rise to the top of the tent, the form of which aids in the ventilation. The tent is constructed of a series of four frames, made of Bessemer rod suitably formed and furnished with hinged terminals; the hinges operating on a stout hinge pin at each end with suitable circular washers interposed to insure independent and easy action in folding the same, the Bessemer rod being hardened to make a stiff, rigid frame to insure its maintaining the original form.

The frame is covered with extra thick yacht sail twill, or similar material, properly fitted, and having elongated ends to admit of their being tucked in under and around the bedding to prevent the cold air from entering the room. The sleeper enters the bed and lowers the tent over himself with the aid of a cord and a little pulley attached to the upper portion of the window. By this means he also raises the window tent when wishing to get out of the bed. Shutters or Venetian blinds, whether they are attached on the inside or on the outside of the window, can be utilized in conjunction with the window tent as a screen to intercept the gaze of the neighbors, and

FIG. 1.—Dr. Knopf's window tent, when in use. Interior view of bedroom.

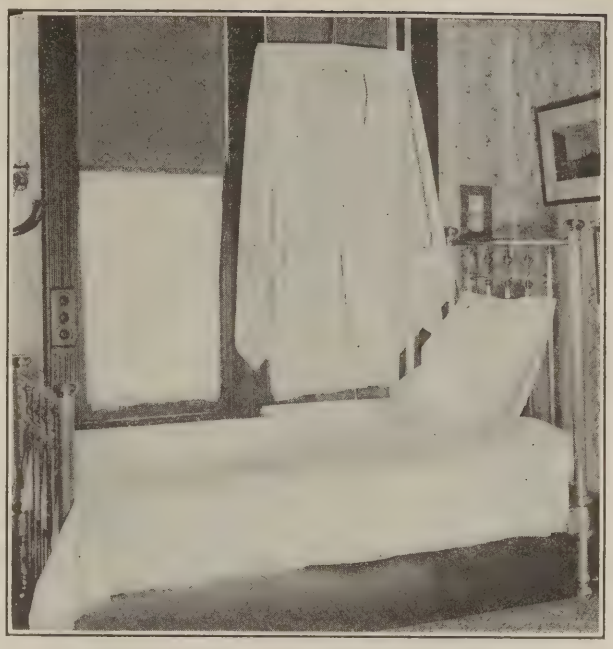

FIG. 3.—Window tent, when not in use, removed by pulley arrangement.

in stormy weather as a protection. The bed can be placed by the window to suit the sleeper's preference for sleeping on his left or right side, so that he has the air most of the time in his face. Another advantage of the window tent is that it will not attract attention from the outside. The bed being placed alongside of the window will be convenient for the majority of the poor who have small rooms. If, however, the bed must be placed at a right angle to the window, this can be arranged as well. A piece of transparent celluloid is placed in the front of the tent to serve as an observation window for the nurse or members of the family to watch the sleeper in case of illness. It also serves to make the occupant feel less outdoors and more in contact with his family, as he can, if he desires, see what is going on in the room. If the bed must be placed at a right angle to the window, the observation glass can be put in on either side. It goes without saying that one should not smoke in the tent because of the danger of the celluloid window becoming ignited. I prefer celluloid to glass, because there is no danger of its breaking when the tent is raised or lowered.

If it is necessary to raise the bed to the height of the window sill, this can be done with little expense. If the bed is of iron, a few additional inches of iron piping can be attached to the legs by any plumber or one handy with tools; raising a wooden bed can be accomplished with equal facility. If the window tent is to serve only during the night, the tent can be pulled up and the bed moved away from the window during the day, and the window closed. Or the tent can be taken from the hooks and put out of the way.

FIG. 2.—View of the window tent, seen from the house opposite.

The folding of the tent and the pulley arrangement are of course not absolutely necessary. A rigid frame can be constructed so as to retain the form with very much less trouble and with a great deal less expense. A cross piece of wood at the top attached to the window frame by a hook at each end, and connected to another cross piece at the bottom by about three curved hoops, giving the form of the tent, will make a good support for the covering. Stiff wire may also be used for the hoops and the covering may be of any material that is sufficiently airtight (Fig. 5).

The window tent, of course, is of greatest service in winter, whether to the well or to the sick. In hot weather the tent is likely to become stuffy, there being little difference in the temperature of the air in and outdoors to aid in the circulation. In cold weather, however, it is ideal, and if the sleeper is not feeling well, or is actually sick and feverish and his stay in bed is advisable, he can spend his entire time in the tent.

Those unaccustomed to sleep out of doors will often complain that the bright light awakens them too early in the morning, and that they have difficulty in going to sleep again. In such instances I counsel to have some light weight but dark colored material (such as a black lisle thread or cotton hose) to put over the eyes.

It will be observed that by merely closing the window and raising the tent the sleeper finds himself in a warm room, ready to wash and dress, refreshed for his daily task by a good night's rest in the freshest and purest air possible.

Since it has been demonstrated that pure, fresh and cold air by day and by night is most valuable,

not only in tuberculosis but also in many cases of pneumonia, the window tent may serve also in such cases. It has been advantageous in certain nervous

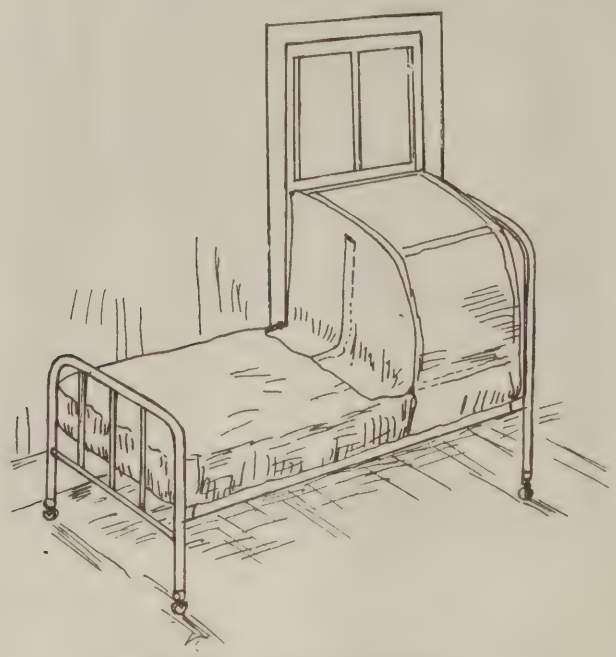

FIG. 4.—Diagram showing ventilation of window tent.

afflictions and anemia. In fact, in order to remain well and strong and guard against disease, sleeping in the fresh, pure air is perhaps one of the best known means. The appeal for winter outdoor sleeping in the Bulletin of the National Tuberculosis Association justly concludes: "The lungs that inhale outdoor air for eight hours out of twenty-four are not a fertile field for the tubercle bacillus." The window tent may be helpful where the sleeping on roof or veranda is not feasible. In a well constructed window tent it is utterly impossible that there could be any draught, nevertheless the sleeper should be warmly clad and should especially protect the upper portion of his body which is in the tent.

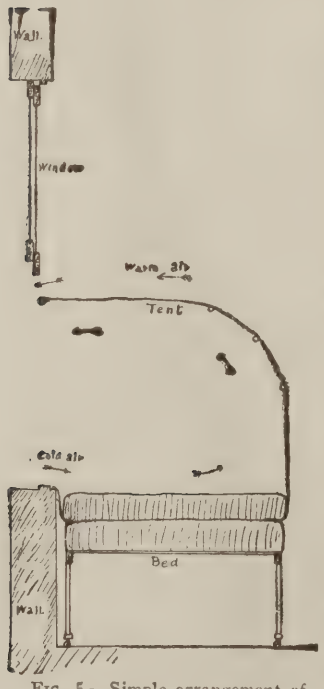

FIG. 5.—Simple arrangement of a window tent.

My own personal experience in sleeping outdoors for many years at all times of the year, even on extremely cold nights in the city in my window tent, has taught me a few things about the necessity of being properly dressed and prepared when sleeping outdoors in excessively cold weather. Even warm coverings and night gowns or robes will not keep the body sufficiently warm unless one wears closely fitting drawers and undershirt or union suit of cotton flannel. It may be, however, that wool is preferable for some. Individualizing is here as essential as in many other things appertaining to the prevention or cure of disease. The sleeper must have a sufficient number of blankets to assure his absolute comfort and warmth throughout the night. Still, the covering should not be so heavy as to press down upon the body and make one feel uncomfortable. To the poor, whose disposal of blankets is, alas, often limited, it may be good advice to tell them to put several layers of newspapers between the coverings, or to sew half a dozen layers of papers between two layers of flannel will make a cheap, light and warm covering. The feet must be kept warm with the aid of hot water bottles or heated sand bags. Even when the weather is only moderately cold, to have the bed warmed before entering it will be found pleasant and help to induce sleep. In extremely cold weather, while sleeping in the window tent, one should dress, so to speak, for the occasion, protecting one's head and ears with a woolen cap, shawl or woolen helmet, such as is shown in Fig. 6. Some will not feel the cold in their face, no matter how low the temperature, except in the tip of the nose. A simple way to keep this portion of the olfactory organ warm is to put over it a piece of absorbent cotton and fasten it with the aid of a strip of adhesive plaster along the crest of the nose, taking care not to occlude the nostrils.

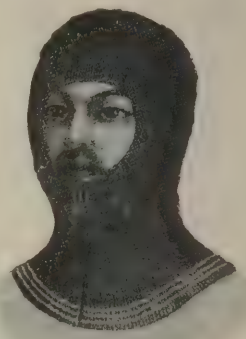

FIG. 6.—Woolen hood for outdoor sleeping in winter.

I am grateful to the late Dr. Theodore C. Janeway for having called my attention to a good method of protecting the shoulders which, with the ordinary arrangement of pillows, are insufficiently covered in extremely cold weather. The same method had been described in the *Journal of the Outdoor Life*, from which I quote as follows: "In the ordinary arrangement an open space is almost sure to form between the pillows, the bed clothing, and the shoulders, allowing the cold wind to blow down one's back. A good way to avoid this is to arrange the two pillows in the shape of a narrow V, with the apex at the head of the bed and the other ends reaching down underneath the clothing. With this arrangement one places his head upon the apex of the V, with his one shoulder between the pillows; the pillows can then be tucked closely up on each side, the covers lie closely down upon them, and no air space can form. This arrangement has the added advantage of making the pillows support a part of the weight of the clothing."

The article mentioned in the fall campaign Bulletin of the National Tuberculosis Association concludes as follows: "Why should not the United States become a nation of outdoor sleepers?" I take it upon myself to assure all the readers of the an-

nouncement in the Bulletin, entitled "National Tuberculosis Association Inaugurates Winter Outdoor Sleeping Campaign" as well as the readers of the MEDICAL JOURNAL AND RECORD, that the campaign is intended to reach the rich and poor alike, and I hope the publication of this article will remove any possible misunderstanding about the aims and objects of the National Tuberculosis Association, and the outdoor sleeping campaign in particular.

The majority of the readers of the MEDICAL JOURNAL AND RECORD are general practitioners who, being also the health counsellors of many patients and their families will, I am sure, be glad to cooperate in promulgating this healthgiving measure. In this way the National Tuberculosis Association's Winter Outdoor Sleeping Campaign will get a splendid start.

16 WEST NINETY-FIFTH STREET.

Determinations Necessary to Adjust Insulin Doses

H. E. LE FEVER, A.B.
Glouster, Ohio

Insulin has now been used in the treatment of diabetes mellitus for a period of three years and during that time many things have been learned concerning this drug. Of the things learned, the one, perhaps, which is the most important, is the knowledge that the mere fact that the patient has diabetes is not an indication for the administration of insulin. The patients, therefore, who present themselves for treatment should definitely be placed in one of two groups, i. e., those who require and those who do not require insulin. It has been conservatively estimated that seventy-five per cent. of the diabetic cases can be controlled by the diet and limited exercise alone; so it should ever be borne in mind that the introduction of insulin did not in the least minimize the importance of careful and scientific dietary management of the diabetic patients, but, on the contrary, greatly increased the importance of it; for, except in the cases of severe acidosis or other serious complications, it is the manner in which the patient responds to the dietetic management that determines whether or not insulin is indicated.

DETERMINATION OF ENERGY REQUIREMENTS

The diabetic diet is essentially a restricted diet and while it should meet the caloric requirement of the patient, it should not exceed it. This minimum requirement will vary in different patients; however, it is thought that from twenty-five to thirty calories for each kilogram (2.2 pounds) of body weight is perhaps sufficient for the majority of cases of diabetes. For example, a man weighing fifty kilograms will require as a basal diet ($50\times30=1500$) fifteen hundred calories.

If the patient is of normal weight or below normal weight, one gram of protein may be given per kilogram of body weight daily, but in the event that he is above the normal weight for the age and height it is wise to cut the protein intake to two thirds gram per kilogram of body weight. As each gram of protein will yield four calories, the total number of calories derived from the daily protein intake will be ($1\times50\times4=200$) two hundred calories.

Diabetics who are not obese may safely take 2.5 grams of fat per kilogram of body weight daily and those who are inclined toward obesity should receive but two grams per kilogram of body weight. Each gram of fat will yield nine calories and therefore the daily required amount of fat will give ($2.5\times50\times9=1,135$) 1,135 calories.

As diabetes is a condition in which the fundamental defect lies in the fact that there is a lowered limit of utilization of glucose, an intermediary product of not only carbohydrates but of protein and fat as well, then it is essential that the diet be so adjusted that the quantity of glucose may be brought within the limits of utilization. This is accomplished by first getting the patient sugar free, which can usually be effected by an initial diet of thirty grams of carbohydrates, thirty grams of protein and thirty grams of fat daily for three days. If at the end of this time the patient is sugar free then the amounts are gradually increased until the basal requirements are approximated, during which time the urine should be most carefully watched to determine the moment sugar appears. If by this procedure a satisfactory diet can be attained without glycosuria, excessive glycemia or acidosis insulin is not indicated and the patient can be controlled by dietary measures alone. When, however, the patient does not respond to this management and the glycosuria persists when the carbohydrate given is equal to the minimum protein intake (two thirds gram to the kilogram of body weight), then insulin is indicated.

TO ESTIMATE THE INITIAL DOSE

The initial dose of insulin is based on the number of grams of sugar excreted in a twenty-four hour output of urine, one unit of insulin being administered for each two grams of sugar excreted (the method of determination to be described later). It is far better to separate the twenty-four hour output into three specimens, one from breakfast to luncheon, one from luncheon to dinner and one from dinner to breakfast of the following day. Each specimen is examined, the number of grams of sugar determined and the three sums totaled. Thus if it is estimated that there were ten grams of sugar excreted in the twenty-four hour output, then the patient would receive five units of insulin as an initial dose.

QUANTITATIVE DETERMINATION OF SUGAR IN URINE

The quantitative determination of sugar in urine is of utmost importance during the time the patient is under the insulin treatment. The quantitative method for the estimation of sugar in urine enables

us to determine the severity of the disorder as well as to follow its course under treatment. As long as the patient excretes a very slight per cent. of sugar in the urine it is an indication that too much insulin is not being administered, but should the urine continue to be sugar free, and if within from three to six hours after the treatment has been given the patient complains of sudden weakness, sweating, tremor, diplopia and anxiety or fear, it is a certain sign that the drug is either being given in too large doses or that it is being administered too frequently. Therefore by running a quantitative test for the amount of sugar present in the urine the results will be an index which will aid us to determine the amount and frequency of the dose.

A test which is both simple and accurate is one known as Benedict's micromethod. The reagent is inexpensive and stable. It consists of:

Copper sulphate (crystallized)	18.0 grams
Sodium carbonate (crystallized)	200.0 grams
Sodium or potassium citrate	200.0 grams
Potassium thiocyanate	825.0 grams
Potassium ferrocyanide (5 per cent solution)	5.0 c.c.
Distilled water q. s. ad.	1000.0 c.c.

The carbonate, citrate and thiocyanate are dissolved by the aid of heat in enough water to make about eight hundred c. c. of the mixture. Dissolve the copper sulphate separately in about one hundred c. c. of water and pour the solution slowly into the other liquid with constant stirring. Add the ferrocyanide solution, cool and dilute to exactly one litre.

Procedure: Five c. c. of this reagent are placed into a test tube and about one gram of sodium carbonate added. The solution is brought to a vigorous boil with continued gentle agitation, the tube being held in the left hand, employing a folded paper as a test tube holder. The urine is placed in a five c. c. burette and with the right hand the urine is run in, a drop at a time, until a chalk white precipitate begins to form. The urine is now run in carefully until one drop dissipates the last trace of the blue color, indicating the end point of the reaction. The height of the urine in c. c. is then read on the graduations of the burette.

Calculation: Since five c. c. of the reagent require exactly ten mg. of glucose for reduction the calculation may be made simple, the urine used in c. c. divided into one will give the percentage of glucose present. As for example: If one quarter c. c. of urine were used, $.25 \div 1 = 4$ per cent. glucose present. With this method the urine should be diluted if the percentage exceeds 3.5 per cent. To estimate the number of grams in a daily output of urine the calculation is equally as simple. If the daily output is one thousand c. c. and the amount of urine required to reduce the five c. c. of the reagent was found to be one c. c., therefore each c. c. of the urine will contain ten mg. of glucose, $1{,}000 \times 10 = 10$ grams of glucose in the daily output.

The percentage of glucose may be determined daily by this method as long as the patient is under treatment. It will not only minimize the danger of reducing the blood sugar to such a point that the condition of hypoglycemia exists, but will be an ineffable aid in ascertaining the carbohydrate tolerance.

A curve may be plotted showing the daily percentage by using the horizontal line or the abscissa upon which to place the number of tests and employing the vertical line or the ordinate upon which to place the percentage, starting at zero and running to five per cent.

The presence of acetone and diacetic acid in the urine may mean that too much fat is being ingested in proportion to the carbohydrate intake; for it is indeed the truth that fats will burn in the flame of carbohydrates, or it may mean that the carbohydrate metabolism is faulty, in which case the amount of insulin should be increased. It is therefore of great importance to determine the moment these substances appear in the urine, for it is the accumulation of these properties in the blood which result in acidosis and coma. When acidosis or coma occur in diabetics, the insulin treatment is to be begun at once without determining the effect of diet.

TEST FOR ACETONE

A most satisfactory test is the one devised by Legal. It consists of introducing five c. c. of urine in a test tube, adding a few drops of an aqueous solution of sodium nitroprusside and rendering the mixture alkaline with potassium hydroxide. A ruby red color results which is either due to creatinin, a normal urinary constituent, or to acetone. Add an excess of acetic acid; if acetone is present the red color will be intensified, whereas in the absence of acetone a yellow color results. A control test on normal urine will show that this is true.

TEST FOR DIACETIC ACID

A simple method for determining the presence of this substance in pathological amounts in the urine is by means of the ferric chloride test of Gerhardt. The technic is as follows: Place five c. c. of urine in a test tube and add ferric chloride solution, drop by drop, until no more precipitate forms. In the presence of diacetic acid a Bordeaux red color results.

A positive result from the above manipulation simply indicates the possible presence of diacetic acid and in order to assure one the test should be repeated, first boiling the urine, and then if the test is negative after boiling one can be certain that diacetic acid is present. A positive result after boiling indicates that the red color is due to some other substance.

Antidote for Arsenic, Bismuth, and Mercury Poisoning.—Henry C. Semon (*British Medical Journal,* April 12, 1924) obtained some very good results in cases of arsenic, bismuth, and mercury poisoning with chemically pure dehydrated sodium thiosulphate put up in ampules in doses of 0.45, 0.6, 0.75, and 0.9 gram. Although the results are suggestive of a specific antidotal action they are by no means conclusive because of the limited number of cases. If, as is presumed, the action of the thiosulphate is to neutralize the arsenic, good results can only be confidently expected if treatment is commenced immediately the toxic symptoms are apparent. The importance of early recognition and treatment of these cases cannot therefore be overemphasized. This treatment may be found to be an indispensable adjunct in the treatment of all cases of acute metallic poisoning.

A Synopsis of Physiotherapy to Date

JAMES T. WRIGHT, M.D.,
Pittsburgh, Pa.

The equipment for a modern physiotherapy clinic should include all the recognized modalities, such as in electrotherapy, static high frequency, galvanic, faradic, sinusoidal, x rays, and ultraviolet rays (Alpine sun lamp and Kromayer lamp); in mechanotherapy, massage, Swedish movements, vibration, etc.; in hydrotherapy, Scotch douches, sprays, needle, shower, sitz, continuous aud whirlpool baths; in light and heat therapy, electric light cabinets, and a full set of radiant light and heat applicators. This outfit is used in government reconstruction hospitals, as well as in others.

Physiotherapy is really a help to establish medical and surgical treatment in any class of cases, including the insane, after first using laboratory, operating room and ward treatments, and where the reaction of the body to disease is inadequate and the disease continues, eventually becoming chronic; and the effort is made to convert this inadequate reaction into an adequate one through physiological response, and the result of the prognosis depends on the patient's response to the treatment.

Physiotherapy is a word coined by the army and includes treatment by all physical measures, and may be divided into electrotherapy, phototherapy, thermotherapy, hydrotherapy, actinotherapy, röntgenotherapy, massage and exercise.

ELECTROTHERAPY

Electrotherapy is the use of electricity in its various forms and includes galvanic electricity, the action of which current is purely chemical and is used where ionization is required for the induction of chemicals into the tissues. The positive pole has analgesic, antiseptic and hemostatic properties and repels bases, metals and alkaloids. The negative is opposite and repels acids and acid radicals. The negative will soften scar tissue and is used in treating urethral strictures, and galvanism with electric needle is used in removing hair. The faradic current is used merely in exercising muscles and improving the circulation, and abolishing local anesthesia.

The sinusoidal current is a sine wave that gradually increases from zero to its highest peak of intensity, from which it recedes back to zero. It causes powerful and painless contraction of both voluntary and involuntary muscles and stimulates metabolism. It is employed in muscle testing, in the treatment of muscle spasm, paresthesia, and paralyzed muscles. It is useful in the treatment of amenorrhea.

High frequency currents are alternating in character and of very great frequency (800 to 1,000 alternations a second) and when these currents of high voltage and frequency pass through living tissue tremendous resistance is encounted and a great portion of the electricity is converted into heat within the body, and the therapeutic result is due to the heat. This is known as diathermia, and spasm and congestion are relieved as well as other types of neuritis, and active leucocytosis induced. The two currents used are the D'Arsonval and the Oudin and can be used for autocondensation and diathermia. Autocondensation will reduce high blood pressure and is much used for that effect. The Oudin current is used in the destruction of warts and moles. The static current is soothing to the nerves, acts mechanically, and generates ozone.

PHOTOTHERAPY

Phototherapy is treatment by means of white and other lights. When light energy is stopped it becomes heat, and sunlight and other lights penetrate to the muscles and generate heat in the muscles. Light also gives off radiant heat and will accomplish all that poultices, mustard or other counterirritants will do. Hemoglobin absorbs light, and gives up its oxygen more readily than when dark. The mercury Alpine sun lamp and the Kromayer water cooled lamp have proved very efficacious in treating intractable skin diseases, infected tonsils, enlarged lymphatics, and similar conditions, and are generally included with every x ray treatment outfit. Finsen has done a great work in heliotherapy. The ultraviolet light is not only germicidal to a great degree, but also tonic in its effect. It does not pass through ordinary glass. The wave lengths are shorter than the shortest rays of the sun and are more efficient. The unit of wave measurement is called an angstrom unit.

HYDROTHERAPY

The use of hydrotherapy is too well known to admit of discussion and the only new thing is the whirlpool baths in the treatment of injured peripheral nerves, and stumps after amputation.

RÖNTGENOTHERAPY

Some time ago I read a paper on x ray treatment in which I stated the wonderful effects obtained in tuberculous glands, in chronic infected tonsils and various skin diseases—notably eczema, the tineas, psoriasis and epithelioma; also in exophthalmic goitre, and enlarged joints.

MECHANICAL VIBRATION AND MASSAGE

By this means some really marvelous results may be obtained in certain chronic diseases. Kellogg says the spine may be likened to "a harp with a thousand strings" and by accurate manipulation of certain spinal areas the function and metabolism of distant viscera in neural connection with the spinal segment, over which the stimulation is applied, may be modified at will. If vibratory stimulation is applied over the posterior branch of a spinal nerve the stimulus is imparted to the sympathetic ganglia with which it is connected, which in turn conveys the stimulus, or inhibition, to the distant viscera which it controls, thereby modifying its function.

The use of massage as a means of stimulating flabby inactive muscles, increasing circulation and

nerve tonus—besides its soothing effect—is well known and practised in all modern hospitals and sanatoria.

EXERCISE

Various forms of exercise are used in modern hospitals. These include the use of parts of the body which have been limited in their motion, from whatever cause, such as partial paralysis, ankylosed joints, contracted scars, atrophied muscles; and in the reeducation of the leg muscles of tabetics, etc.

The Army found boxing and dancing very beneficial as well as the "setting up exercises."

CONCLUSION

1. A fully trained physiotherapy aide is an essential in present day hospital or private practice.

2. Much can be done by this means that medicines alone will not reach, and the same should be duly considered.

3. The general profession should study and know these modalities and apply them, and thus weed out quacks and irregulars.

4. A complete course in physiotherapy should be given in our medical schools.

Interpretative Value of the Physical Signs of the Heart in Acute Rheumatic Endocarditis in Children*

SAMUEL A. BLAUNER, M.D.
New York.

It is a strange fact that despite rapid strides in medicine, especially in hematology and bacteriology, the origin of rheumatism still remains shrouded in mystery. As we survey the morbidity tables of the first two decades of life we realize how deep an influence rheumatism with its manifold manifestations and complications plays upon the growing child and recognize that if we are to overcome some of the maiming effects of this disease we must at least gain more accurate knowledge of its etiology.

The importance of rheumatism is not within the disease itself but rather in its great tendency to attack the heart. If with an initial attack, an immunity would be conferred, its depredations would not be so evident, for despite a severe onslaught, the child's heart is usually capable of adjusting itself to the increased demands of the growing organism. It is this lack of immunity together with the tendency to repeated attacks on the endocardium that makes the problem of rheumatism in childhood one of prime importance.

Rheumatism manifests itself in various ways, not infrequently with such slight fleeting pains that its importance is minimized. Irrespective of the manner of onset it must be remembered that the cardium can become involved and discovered only by an incidental examination. In fact, primary rheumatic endocarditis with no other general rheumatic manifestations often occurs, and not infrequently we see patients who have fairly well developed organic lesions having no knowledge of either previous pains or febrile conditions. It is possible that in these cases a slight increase in temperature giving but slight inconvenience might have been present and overlooked, but notwithstanding, these cases prove that an acute rheumatic endocarditis can run a more or less afebrile course and escape attention of patient.

Rheumatic endocarditis is a most common condition in childhood, and although organic heart conditions may follow from other infectious conditions, the latter are so infrequently the underlying cause that it is well to look upon all acquired heart lesions in childhood as of rheumatic origin. The origin would not make any difference were the initial attack the final one; but the likelihood of rheumatic endocarditis to recurrence and exacerbations and the impossibility of measuring the severity and termination of the separate attacks, necessarily make our judgment on the prognosis and particularly the general advice on the manner of life and habits of the patient dependent on the presumption that further insult will occur. As a matter of fact rheumatism is by far the predominating cause and even though other agents may play their rôle the latter are relatively so few that it is better, for prophylactic reasons, to consider all acquired organic heart lesions on a rheumatic basis unless otherwise disproved by a history.

It is well at this point to review briefly the anatomy and physiology of the child's heart, to help us understand more clearly some of the manifestations of this disease. It will give us a clearer rationale for our interpretations of symptoms and diagnosis and what is most important a clearer insight into the prognosis and mode of treatment. The child's heart is relatively a much larger organ proportionately than the adult's, and even though the volume and weight steadily increase, the circumference at the beginning of the seventh year remains practically the same as at the end of the first year. During the first year the thickness of both ventricles is practically alike, approximately 0.5 cm., and at the beginning of the seventh year despite a steady increase of weight, the right ventricle has practically remained unchanged, while the left ventricle has instead steadily grown in thickness to approximately four to eight cm. In other words, we have an organ, compact in its make-up, steadily increasing in weight, and developing in such a fashion as to throw its entire strength into the left ventricle. Besides there is an additional factor of no little value. To the already powerful ventricles the child's arteries, which possess circumferences and elastic tissue relatively larger than in adults not only help diminish the contractive requirements of the heart but hold instead a reserve strength to be used as occasion requires.

*Read January 8, 1924, before the Society of Alumni of Lebanon Hospital, New York.

Clinically, as a result of this developmental arrangement, we should expect to find in our endocarditis cases a clinical picture not only different from that in adults, but our interpretation of the separate symptoms and particularly our prognosis should keep these added factors in view. It should constantly be borne in mind that as a consequence of these added benefits the left ventricle can usually take care of the circulation, even in moderately diseased conditions, to such an extent, that neither enlargement of the right ventricle nor accentuation of the second pulmonic tone need necessarily take place. In fact in the ordinary mild or moderate type of endocarditis we must not be surprised to find an absence of these physical signs. If these are present and show no tendency to recede after a reasonable lapse of time, we are in a position to say that the left ventricle alone is unable to take care of the circulation. As a result a poor mediate prognosis is in view, for if a child's heart at an early age indicates symptoms that the left ventricle with its powerful reserve is incompetent to take care of the circulation without producing back pressure symptoms, we can confidently expect that this same heart will be unable to take care of the demands of growing childhood, and this not taking into consideration the increasing damage and weakness that will ensue from the further recurrent endocarditic attacks that come with rheumatism.

Rheumatic endocarditis may start with frank physical signs with or without a previous history. However, just as frequently, the signs will keep themselves in the background so that the diagnosis will only be suspected. In the latter instance the first thing that draws our attention to the condition is the finding of a murmur, but as murmurs are not pathognomonic of organic lesions, it tests our acumen to decide. Of course if the lesion is definitely developed the difficulty is obviated, but in the milder cases with the physical signs confined to an indecisive murmur, particularly in the apparent nonfebrile types, our hesitation begins. A conclusion is not only important for the early precautions that can be instituted, but is of great import in the need of rearranging the entire plan of education and economic preparation to fit in with a steadily increasing infirmity rather than with the patient's social status.

Unfortunately an early diagnosis in these milder cases is not always possible, and only by careful observation may we bring the condition to light. The child's ventricle is sufficiently strong to easily take care of a slight defect in the organ to the extent that neither an enlargement of the ventricle nor an accentuation of the second pulmonic tone will occur —two important diagnostic signs.

The only sign that does present itself is that indecisive murmur; but here we are met with the difficulty of this murmur being similar in character to several other murmurs frequently heard over the precordium which are nonorganic.

For the sake of review it would perhaps be better to mention some of the more common murmurs heard over the precordium in childhood and to enumerate them according to their clinical and diagnostic importance. 1. The true acquired organic lesion usually rheumatic. 2. The various forms of congenital heart lesions. 3. A systolic murmur not organic in character heard at the base and heard more or less persistently till early adolescent life and extremely difficult to separate from a true congenital murmur. The nonrecognition of this murmur accounts to my mind at least for the occasional report of cure of congenital heart lesions. 4. The true functional murmurs heard so frequently in childhood and elicited both at the base and apex and when heard at the later situation if at all persistent, so extremely difficult to differentiate from a mild form of true organic lesion. 5. The cardiovesicular murmurs, extracardial in character yet often enough confusing for a true evaluation. 6. The murmur described by Eustace Smith in adenopathic children, and called by his name and heard prominently at the upper part of the sternum, in the region of the base of the heart.

In all these instances the murmur is usually systolic in time and while some are heard most prominently at the apex or near the apex, others are heard at the base or over the entire precordium. All with the exception of the Eustace Smith murmur, possess the property of being heard about the apex with sufficient audibility to make it extremely difficult to differentiate from the truly acquired lesion unless other concomitant signs and symptoms come to our assistance.

Even in congenital cases there are instances of mild types, where it is extremely difficult to come to a decision unless a röntgenogram or electrocardiogram comes to our aid. The electrocardiogram will give a typical curve in congenital cases, while in the acquired cases even in the mild types a partial atrioventricular bloc will sometimes be disclosed.

Again, in acute rheumatic endocarditis, irrespective of whether the endocarditis singly and alone signalizes a general rheumatic tendency or whether the endocarditis is present with other rheumatic manifestations, we again meet with difficulty. It is of little importance that a murmur is heard at the apex, because it should be borne in mind that febrile conditions in children readily call forth nonorganic murmurs and if in addition we will consider that acute endocarditis in the beginning can be present with no audible murmur and furthermore that nonorganic murmurs present before the onset of temperature will readily be accentuated, we will understand why the entire problem of early diagnosis is confusing and why many cases are improperly diagnosed. The result is that these patients are either put to bed unnecessarily or go untreated at a time when treatment is most vital.

It would seem that any injury incurred by the cardium in addition to the toxemia that always accompanies the acute cases, would produce sufficient inequality of the circulation to give at least some physical signs of the heart. However true this might be of adults, our picture is changed considerably in children because of the powerful left ventricle and unless the lesion is severe or extensive enough to give us this inequality of circulation, signs of enlargement of the heart and particularly enlargement of the right ventricle and change of character of tone, will be consistently absent, signs so prominent in older patients.

True there is enlargement, and early enlargement of the heart, but it is no more than the usual en-

largement that occurs in children's hearts under stress and with temperature, because of its high accommodative and expansile powers; but the true gradual dilatation and compensation that come with the initial inefficiency of the heart muscle and back pressure in the general circulation and in the lungs are absent. It should be kept in mind that the left ventricle under ordinary conditions is capable of taking care of the moderate lesion and when it becomes inefficient, the point to be remembered is that the left ventricle alone participates in the dilatation and compensation and not both the right and the left ventricle as is usually found in adult cases. The left ventricle, with its ability of quick compensation, is soon able to take care of the circulation so that there need be neither enlargement of the right chamber of the heart, nor the stasis in the lungs to produce the accentuation of the second pulmonic tone. So in observing acute febrile cases with suspected endocarditis, we should remember that we cannot in mild cases at least in the beginning depend on the physical signs of the heart to give us a clue to the diagnosis. Nor can we depend on the murmurs present to clear the picture unless other symptoms are present, for it was pointed out that these murmurs often are indistinguishable from nonorganic murmurs heard over the heart. Nor can we depend, as we have seen, on the heart's reaction in size or change of character of the tones to assist us. As a result of these factors many of these cases are missed or go undiagnosed for a variable period. Fortunately, however, not all cases present these initial difficulties. Depending on the virulence of the infection and extent of valvular involvement the diagnosis in many cases is established early; the murmurs become typical, the left ventricle enlarges and hypertrophies, even the right ventricle participates in the change, and what is helpful even in the milder cases, some form of pericarditis may ensue.

We realize how important it is to make an early diagnosis and yet how unreliable the physical signs can be, but there is one sign I feel not sufficiently stressed, and which I believe is of considerable help in doubtful cases; that is the character and rapidity of the pulse. We must be careful, of course, in interpreting a child's pulse in febrile conditions for the pulse is easily influenced by temperature, but in the presence of other suspicious symptoms, especially a murmur, a persistently rapid pulse disproportionate to the temperature will frequently lead us to a correct conclusion. McKenzie has pointed this out, and I am inclined to believe with him that when present this is a most important and early diagnostic sign of all forms of acute endocarditis. Besides the rapidity of the pulse, to give this symptom greater diagnostic value, there should be an entire absence of sinus irregularity. I do not mean the absence of sinus irregularity which so regularly occurs in children with febrile conditions, reappearing again with the decline of the temperature and slowing of the pulse, but rather that constant regularity irrespective of the degree of temperature, and no doubt as the result of the constant acceleration of the pulse no sinus irregularity can possibly interpose itself.

With the severe and developed case of acute endocarditis the problem of diagnosis is simple. Although the onset may be insidious and the symptoms for the moment in abeyance, it is not, however, long before the signs show themselves; the temperature assumes the remittent character; the murmur is typical and is transmitted along the line of least resistance; the second pulmonic tone may become accentuated especially in those cases where there have been repeated exacerbations and a certain degree of back pressure is already present, and what is of prime importance, the left ventricle progressively enlarges. The right ventricle even here does not have to enlarge to any great extent. If it does it simply means that we are dealing with a severe infection or possibly repeated recurrences and exacerbations have consumed the reserve force of the left ventricle with the resultant participation of the right chambers of the heart, to stave off if possible a threatening decompensation. This is the usual picture of the typical severe case of acute endocarditis and may continue so, with oscillation, for weeks, unless a pericarditis with effusion supervenes, when the entire syndrome may promptly change.

Strange as it may seem and as desperately ill as some of these patients appear, a careful analysis of the symptoms will show that the severity of the illness is not due to circulatory disturbance *per se*, as one would expect, unless, of course, there ensues an accompanying effusive pericarditis when pressure symptoms may arise, but rather the severity of the illness is due directly to the virulence of the infection. As a matter of fact the lesions of the heart will participate little in the production of symptoms even though the lesions present are severe and extensive. To do so there would have to be circulatory disturbance and the favorable fact that even under stress of infection the heart and particularly the left ventricle is able properly to take care of the circulation makes the bedside problem for the moment one of infection rather than one of circulatory disturbance.

Complications in acute rheumatic endocarditis are not common and the most frequent one as we know is pericarditis. It is often a troublesome complication and can become severe enough not only to overshadow the endocarditis but actually to endanger the patient. If the pericarditis is fibrinous in character or the amount of fluid deposited is small, we can then momentarily disregard its influence except for its confirmatory evidence in an otherwise doubtful or suspicious case, or in other instances, its bearing at some future day on the development of the troublesome form of adherent pericarditis. But if it is severe and progressive and producing symptoms of its own, early cognizance should be taken and interference instituted when indicated. The heart enlarges upward and downward to the left and to the right, to the right more than it does in acute endocarditis without pericardial involvement. The tones are muffled and the pressure in all directions may become so great that true decompensation may set in. It is really surprising how large the pericardium may appear on percussion and yet how often the effusion is mistaken for a dilated heart. If we keep in mind, however, that only under exceptional conditions will the right heart enlarge considerably, its presence will promptly arouse our suspicion. Ordinarily with the usual methods of examination it is not a simple matter to map out an effusion, to follow its progress and particularly to decide when to inter-

fere; but in the hospital we have employed the sign developed by Dr. Haas—the socalled double line—and which has helped us considerably to detect all grades of this condition. With the help of this sign, we follow the progress of the effusion, and it is not necessary to interfere unless the pressure signs become advanced. It is not unusual for the heart to take care of considerable fluid and get well without interference, but in a series of cases where the pericardium is stretched markedly, the lungs completely compressed and dyspnea advancing, the symptoms become urgent enough for relief to be instituted. Much need not be withdrawn, just an ounce or two, and then resorption will begin and the fluid disappear. It must be kept in mind also that the pressure of the lungs can become so marked that the entire lung with the exception of a small area, as pointed out by Dr. Conners, high up in the axilla and another area near the costodiaphragmatic sinus may become completely obliterated. The result is that more or less complete flatness is heard over the posterior chest and, together with the bronchial breathing caused by the lungs being compressed over a large bronchus or over towards the hilus, frequently leads to the mistaken diagnosis of either a lobar pneumonia or pleurisy with effusion.

Another important question, in cases requiring interference, is to decide the point of election for the insertion of the needle. The customary place is immediately to the right or left of the sternum. This site has been attended by too many failures even in cases where it is positively known considerable fluid is present in the pericardium. It has occurred to me that anterior puncture is not a rational procedure at least in those cases with marked pressure symptoms. For if such symptoms can be produced, the lungs are either completely pushed aside or there can only be a layer of compressed lung between the sac and posterior chest wall. Under these conditions the rational procedure would be a posterior puncture at about the angle of the scapula. The entering needle will find itself either directly in the pericardial sac or at the most through a layer of compressed lung which can do no harm at all. We have attempted this route in several cases with most encouraging results. On account of one untoward incident it was discontinued for a time but recently it was resorted to again successfully and I am inclined to think with more experience this route will become the one of chonce. Recently, in a lecture on pericardial effusion, I was much gratified to learn that Dr. Conners uses the posterior route exclusively and successfully. He pointed out by diagram and chart of cadavers, that the heart occupies completely the mediastinal space between the spine and sternum and cannot of necessity enlarge nor hold any fluid between these points and can do so only in the lateral direction by pushing the soft lung before it. This route, anatomically and clinically, is and should be the route of election.

Another rather difficult problem is one where an acute febrile condition interposes itself on chronic endocarditis. As exacerbations are common in acute endocarditis, the temperature may be an expression of a reinfection and it is evident that early recognition for the sake of treatment should be as prompt as possible. The reinfection may insinuate itself similarly as with an initial attack of acute endocarditis, that is, mildly or virulently. As a rule, the virulent attack will be promptly recognized for all the physical signs will rapidly change. There are instances where the reinfection is so overwhelming that it is difficult at first thought to decide between a reinfection or acute decompensation. It would seem that a fine differentiation between the later two would be unnecessary, yet if we are to have a clear insight as to the probable immediate outcome an attempt at differentiation should be made. It should be remembered that an acute decompensation means that the powerful reserve force of the child's heart has been entirely consumed and has no where else to look for assistance; but where it is only a reinfection, even though a virulent infection, the reserve strength of the heart, especially that of the left ventricle, may still be there to serve its purpose. Therefore we can give an immensely better prognosis. Important as it is, it is not an easy matter to separate the two and the entire thing will depend on whether we were fortunate enough to have known the nature of the signs immediately before the onset of the present attack. If the signs change rapidly to the right as well as to the left and some of the secondary symptoms as dyspnea, large liver or edema, are present, we are probably dealing with an acute decompensation, but where the changes confine themselves primarily to the left side of the heart, the secondary circulatory symptoms being insignificant, the temperature remaining high and persistent, together with the possible formation of a pericarditis, we can assume a reinfection. On the other hand in the mild types of reinfection, we may have no new symptoms to rely on except a persistent temperature, the heart apparently remaining the same. The signs do not change unless an additional pericarditis, which is always pathognomonic of infection, sets in. In these cases we have no other recourse but to depend on observation, and the rapidity and character of the pulse.

In estimating the prognosis of a particular case, it should be constantly borne in mind that the life of the patient is directly commensurate with the strength of the heart and particularly the left ventricle. It would seem that the heart in its evolutionary development has been endowed with a strength that can be affected only by a tremendous insult and that this strength is particularly evident in childhood. We observe repeatedly at the bedside that despite stress and infection the circulation is usually equably maintained and only rarely is circulatory failure in the sense of a decompensation present and then as a rule because of repeated infections or because of pressure symptoms from an accompanying pericarditis. Only occasionally do patients die and these not in the strict sense from heart failure but rather from the infection or some action of the infection. These patients are often desperately ill, their hearts being under tremendous stress, but the circulation holds and unless the toxemia becomes too great or some unwelcome complication arise, they will frequently rally and recover from the acute attack at least. The immediate prognosis then is good and only when the signs and symptoms indicate a progressive loss of strength of the heart does the outlook become grave, but fortunately because of its developmental strength, as was pointed out above, this is not common.

CONCLUSION

In conclusion, let me add that whatever the sequelæ, the immediate outcome is usually good and good because, despite the severity of the infection, the heart is usually able to maintain its circulation, on account of the inherent strength of the left ventricle given to it by developmental preference.

1323 MADISON AVENUE.

Infection With Staphylococcus Albus*

MARK GORDON, M.D.,
Brooklyn, N. Y.

CASE.—L. J., male, aged twenty-seven, single, born in the United States, by occupation a musician, was admitted to the hospital on February 28, 1923. He complained chiefly of pains throughout the body, sweating, cough, chills and fever. He had had measles but no other childhood diseases. At eighteen years of age he had had an attack of bronchitis which lasted a few weeks. Occasionally, within the last few years, the patient had had attacks of pain in the epigastrium followed by vomiting. This usually occurred after an indiscretion in diet. After vomiting he felt relieved and would fall asleep. Otherwise the patient had been in fairly good health. He was not regular with his meals, eating one or two meals a day with little appetite. He did not use tobacco or alcohol.

His present illness started two months before. Pain developed suddenly in the right knee, which spread rapidly and in about two days involved every joint and muscle in the body. At the same time the patient had spells of dizziness and weakness and felt feverish, which became worse daily. His sleep was disturbed on account of the pain. He would doze off and in half an hour would awaken perspiring profusely, after which he felt weak. This had continued for the past six weeks. Cough had been present from the beginning, with slight yellowish sputum. Four days previous to admission the pain became more severe and he felt chilly at times. He was confined to bed for the first time. He had had very little sleep for the past three or four days on account of pain. During the past two months he had lost twenty-eight pounds in weight. Associated symptoms included cough, some pain in the chest, sputum of yellowish character, poor appetite and constipation. The genitourinary system was negative, also the cardiovascular.

Physical examination showed the patient to be a male, very well developed and fairly well nourished, with hemic component fair and muscle tone fair. He appeared to be in pain. The head was moderately large, with no undue prominences or abnormalities present. Pupils reacted to light and accommodation. There was no ptosis. In front of both ears there were areas of discoloration and tenderness. The nose showed nothing unusual. There was a foul odor from the mouth; teeth were in fair condition; tonsils were not enlarged or reddened; pharynx was injected; tongue was coated. There were no palpable lymph glands about the neck, thyroid not enlarged.

The thorax was fairly well formed and well covered, the upper left being more prominent than the corresponding right. Respiratory movements were equal at the corresponding levels; there was no lagging. Tactile fremitus was felt throughout equally and there was a good resonant note throughout. The breath sounds were somewhat rougher over the right apex; they were heard well throughout the rest of the chest. There were no râles. Heart: no apex impulse was seen; on palpation a forceful beat was noted in the fifth costal interspace; there were no shocks and no thrills; no abnormalities were heard on auscultation.

The abdomen was slightly rigid, this being voluntary. There were no masses and no tenderness. The extremities were normal in appearance, no varicosities, no edema. All joints in the body were tender and painful on motion, no evident abnormalities, no palpable glands. The skin was covered by an erythematous rash, more evident on the palms of the hands. All reflexes were normal. Temperature, 103°, pulse 90, respiration 20, blood pressure 130/84.

Blood examination showed red cells 4,500,000; white cells 3,700; differential of polymorphonuclears, 62 per cent.; lymphocytes, large 6, small 32; hemoglobin 75 per cent. The urine contained albumin, granular and hyaline casts, and red blood cells.

A diagnosis was made of influenza, polyarthritis with acute nephritis, and septic erythema. The patient was placed on salicylates and alkalies.

On March 3rd the patient was found to be better. The joint and muscular pains were greatly diminished and the pain in the lumbar region was less pronounced. The temperature was gradually coming down and the impression was confirmed that this was a case of influenza with muscular and joint pains and acute nephritis.

Improvement continued until March 7th. On that day a swelling of the nose became evident, there was also edema of the upper eyelids, also induration and ulceration of the lips. There was also evidence of ulceration in the throat. The whole looked like an acute streptococcus infection with particular involvement of the throat. On March 13th the patient again showed considerable improvement. All joint and muscular pains disappeared, there was apparently a normal temperature, and there was subsidence of the local infection of the nose, throat and lips. The patient showed signs of progressive improvement until March 20th, when there was a sudden recrudescence of almost all the symptoms, with a heightened temperature. Vaccine treatment was ordered at this time. An injec-

*Read before the East New York Medical Society, Oct. 29, 1924.

tion of half a cubic centimetre of 500,000,000 of Van Cott's combined vaccine was given. The condition grew progressively worse. On March 29th the patient became irrational, very restless, there was retraction of the head, with symptoms of cerebrospinal involvement. A lumbar puncture was done, some fluid was withdrawn under slight pressure, but examination of the fluid was negative. On March 30th the condition grew very much worse, stimulations were administered, but the patient died.

In all, two blood cultures were made of the patient, both of them showing the presence of Staphylococcus albus. Diagnosis was accordingly made of staphylococcemia. All in all we had three blood counts made in this case and in every instance it showed a leucopenia. The Wassermann reaction was negative, blood chemistry was negative, Widal reaction was negative.

This case is of interest in so far as it is quite rare and is one of the few reported in the medical literature. Looking over the literature, I went as far back as 1910, but could not secure any data earlier than 1921. Dr. Hans Landu, in the *Deutsche medizinische Wochenschrift* for September 8, 1921, reported two cases of infection with Staphylococcus albus. Walton Martin, of New York, in the *Annals of Surgery,* 1922, reported eight cases of infection of the face and lips due to Staphylococcus albus. Professor Rockenheimer, of Berlin, described one case of infection with Staphylococcus albus. Kleigler and Kraus, in the *Medizinische Wochenschrift* of February, 1923, speaking of infectious diseases, discussed infection with Staphylococcus albus at great length, dwelling upon its fatality. Hine, in the London *Lancet* of December, 1922, also spoke of this form of infection and of its insidiousness.

In all the cases that have been reported, it is significant that the onset is about the same. It begins with chills and fever, pain in all the joints, induration and swelling of the lips and throat, and erythema of the skin, and all of them terminate fatally.

Dry Diet as a Diagnostic Test as Well as Therapeutic Measure in Acidosis of Children

HERMAN B. SHEFFIELD, M.D.,
New York

Acidosis in children is a manifestation of faulty fat metabolism and hence is most frequently encountered in children from about nine months to three years of age, a period when mothers, in their anxiety to fatten their children, force upon them, in addition to their milk supply, an excessive quantity of fat in the form of cream or butter in cereals and vegetables, rich soups, bacon and the like. When the abominable fad of top milk feeding was in vogue, acidosis was quite common among much younger infants.

As a rule, the attacks occur periodically, the duration of the intervals varying with the degree of tolerance of fat. While the onset of the attack of acidosis is generally sudden with explosive vomiting, rise of temperature, anuria, drowsiness, and often hyperpnea, careful watching generally shows that the actual attack is preceded by habitual anorexia and tendency to nausea and occasional vomiting, particularly in the morning after partaking of milk. It is especially during this prodromic stage that an acute attack is precipitated by the advent of another disease, such as tonsillitis, influenza, or pyelitis, thus explaining the erroneous assumption that acidosis may occur in epidemic form.

The diagnosis of acidosis is readily confirmed at the bedside by the finding of acetone bodies in the urine and by other well known tests where laboratory facilities are at hand. But I wish to call particular attention to a clinical observation that has for years served me as a true diagnostic guide, namely, the acidosis patients, while violently vomiting fluids, almost invariably tolerate solid foods, such as crackers, sweetened biscuits, or palatable cereal pastes without milk. This symptom has proved to me so pathognomonic of acidosis that it has often enabled me to make a positive differential diagnosis between cases of vomiting accompanying acidosis and those of appendicitis, intussusception, polioencephalitis, and similar conditions, in which latter diseases the patients usually vomit everything, fluids as well as solids.

Furthermore, profiting by this experience I have found it no longer necessary to starve the acidosis patients (and thus aggravate their condition), but, on the contrary, direct that small portions of the aforementioned sold foods be given to them. I also find it advantageous to give bicarbonate of soda, mixed with granulated sugar under the tongue, *in dry form,* instead of in solution, when it usually is promptly ejected. In this manner, especially with the aid of a few enemas of sodium bicarbonate (half an ounce to a pint), the acidosis is rapidly controlled. The regular diet, more especially milk or fats, is not resumed until every trace of nausea has subsided and the urine has become entirely free from acetone. Even then only skimmed milk is allowed for several weeks thereafter. Where the acidosis persists, enemas of glucose solutions (one ounce to a pint) three times a day, are of signal benefit, and, when the case is seen late, or is grave in character, the alkalies and the glucose are best given continuously by Murphy drip or intravenously. Blood transfusion often proves a life saving operation in apparently hopeless cases.

Rectal Surgery Abroad

J. F. MONTAGUE, M.D.
New York,
Rectal Clinic, University and Bellevue Hospital Medical College

We are always quite ready to accept a good excuse for exercising the spirit of *Wanderlust*. Whether this is an instinctive trait handed down to us through countless generations of prehistoric nomadic ancestors or is an evidence of the twentieth century spirit of adventure is undeterminable. Be that as it may there is always present a desire to see for ourselves first hand the places, people and things concerned in the circle of our endeavors. In other words we are prone to track tradition, so to speak, to its lair; to search out those places connected by history or tradition to things we are interested in. And as our interests vary so do the paths of our pilgrimage. If this be true it is quite logical for one particularly interested in rectal diseases to make London the Mecca of his pilgrimage. For it was in London that the subject of rectal diseases was first made the object of special study and attention.

Here in 1835 the St. Mark's Hospital was erected and endowed for the study and care of rectal diseases exclusively. Some nine years later this was followed by the establishment of the Gordon Hospital, which follows in form and principle that of its predecessor in that it admits to its wards rectal cases and nothing but rectal cases. Both of these hospitals have adhered to this policy during the years intervening and have been conspicuously successful. These are the only hospitals in London that devote themselves exclusively to rectal diseases but there is at least one other, St. Bartholomew's Hospital, that handles a large percentage of such cases. London, therefore, with its historical significance to proctologists is the chief point of visit to the rectal surgeon abroad. Indeed there are no places on the continent where a proctologist has an opportunity for either observation or study comparable to that afforded in London.

ST. MARK'S HOSPITAL

In London our first visit is to the St. Mark's Hospital. From the fame attached to its name we expect to see a large hospital but such it is not. It is a modestsized hospital of fifty-four beds, some of which are in the wards and some in private rooms. The hospital is efficiently managed and compares most favorably with our American hospitals of the same size. Throughout the last year the hospital cared for 661 patients, which means that out of the fifty-four beds available about forty-seven were occupied throughout the year. The average stay of the patients is approximately twenty-five days. This will strike one forcibly in contrast with our American practice as the average hospital stay of our own rectal cases is considerably under ten days. Some of us make a practice of getting our hemorrhoid, fistula and other rectal cases (exclusive of cancer) out of the hospital in a week. However, we must not judge too hastily on this point. In the first place the average case that comes to St. Mark's Hospital, and I am told that they come from all parts of the empire, is one which has been given up by everybody else. As a result St. Mark's receives a motley assortment of truly bad cases. This undoubtedly partially explains the difference in average stay. It may be further explained on the basis of the difference in national characteristics, that is the leisurely diligence of the Englishmen in contrast to the hurry hurry methods of ourselves. The English surgeon is not usually in a hurry about such things. But one other reason for the longer period of convalescence unquestionably rests in the fact that most patients receive a general anesthetic, or at least some anesthetic in conjunction with sacral block.

These observations hold approximately in respect to the Gordon Hospital, which is a smaller institution, though quite as efficiently run. At the Gordon there are twenty-eight beds available for use and of these an average of seventeen beds are occupied. Last year 325 patients were admitted and cared for and the average stay of these patients was nineteen days.

INCIDENCE OF TYPES OF RECTAL DISEASE

Relative to the incidence of the various rectal diseases, the experience at St. Mark's gives the chief in the following order of frequency: hemorrhoids, fistula, cancer, ischiorectal and anal abscesses, fissure, pruritus and prolapse. During the year of 1925 there were 602 operations performed at St. Mark's Hospital, of which 459 were males and 143 females. Five hundred and seventy-two of these were discharged from the hospital as cured. Experience at the Gordon Hospital runs practically parallel with this.

PERSONNEL

Before proceeding to a description of the various therapeutic procedures employed, it is well to know something of the men using them. Mr. Swinford Edwards occupies about the same position in England as our own Dr. Joseph Mathews does here. To American proctologists Dr. Mathews is reverently referred to as the Father of Proctology—at least as a distinct specialty. Mr. Edwards is similarly regarded as the dean of proctologists in England. With Mr. Aslett Baldwin he shares the honor of being consulting surgeon to the St. Mark's Hospital. Mr. Baldwin is also the chairman of the Subsection on Proctology of the Royal Society of Medicine. Both Mr. Edwards and Mr. Baldwin are elderly gentlemen and both have contributed much to the advancement of proctology in England. It was, I believe, due to their efforts that the Royal Society of Medicine first granted a subsection on proctology. The gentlemen who are preeminently active in rectal surgery are Mr. J. P. Lockhart-Mummery, Sir Charles Gordon-Watson, Mr. W. Ernest Miles and Mr. Graeme Anderson. The

first three hold appointments as surgeons to St. Mark's while Mr. Miles holds appointments to Cancer Hospital and the Gordon. Sir Charles Gordon-Watson holds an appointment at St. Bartholomew's Hospital.

Of these Mr. Lockhart-Mummery is perhaps the

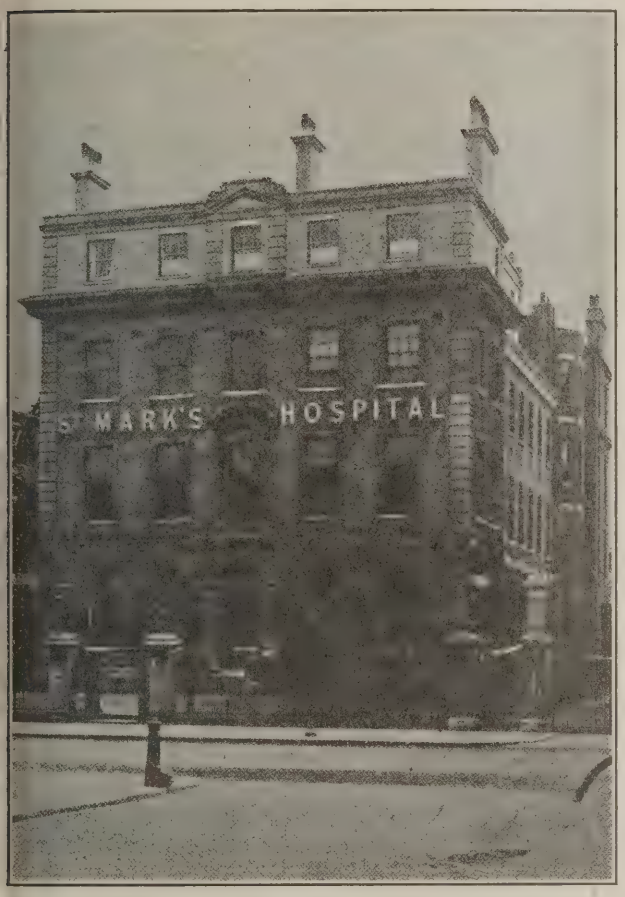

Fig. 1.—St. Mark's Hospital, London.

best known to us in America. This is chiefly through his textbook on *Diseases of the Rectum and Colon.* All four are excellent surgeons and like most Englishmen, polished gentlemen. They have differing views on treatment, particularly on the question of cancer, but their respect for one another is, I must confess, inspiring. Concerning these views more will be said later. Both Sir Charles Gordon-Watson and Mr. Miles are equally active and creditable surgeons. Mr. Anderson, though younger than the others, is a worthy associate, as he is energetic, skilful and exceedingly well informed. Of the younger men, Mr. Cecil Rowntree, Mr. Lionel E. C. Norbury, Mr. W. B. Gabriel and Mr. C. E. Dukes are the best known. Mr. Rowntree is secretary to the Subsection on Proctology of the Royal Society of Medicine and operates at the Cancer Hospital. Mr. Gabriel and Mr. Norbury are assistant surgeons at St. Mark's, while Mr. Dukes is pathologist to the Hospital. The latter has recently completed some very interesting work demonstrating the structure of nerve endings in anal papillæ.

Undoubtedly the big question in most of our minds when we visit a group of such eminent confrères is, "Do they use the same methods as we do?" "What is their experience in the use of these methods?"

In a general way the English use the same methods as we do, with some exceptions to be noted. Considering the fact that the specialty originated in England, this seems only natural. That exceptions are to be found is quite as natural when we reflect on the inevitable modifications each individual makes.

Hemorrhoids, for instance, are dealt with by either surgical or injection methods. The latter method has on the basis of experience been added to the list of approved procedures—wherein perhaps our conservative friends are more progressive than we. Although many American proctologists of repute use this method, it is vigorously denounced by many others and is viewed by the average general surgeon with high disdain. Whether anything more substantial than prejudice or ignorance induces this attitude, is doubtful. Any impartial rectal surgeon who has seen the method used and who has used it himself will come to the conclusions the method is legitimate and has its rightful place among our methods of treating certain types of hemorrhoids. The English, however, seem to prefer carbolic acid (ten per cent. with glycerin and water) to the less dangerous quinine urea hydrochloride. However,

Fig. 2.—Gordon Hospital for Rectal Diseases.

their experience in definite facts and figures seem to substantiate their preference. Mr. Graeme Anderson, among others, is doing much of this work and is having very good results.

Of the operations, the ligature method of Allingham is the one chiefly used, though the clamp and

cautery method is employed in perhaps twenty-five per cent. of the cases. In technic both these are identical with our own methods. Mr. Lockhart-Mummery does not stretch the sphincter in pile operations. It surprises one to learn that the Whitehead operation is still used. Last year nine cases were operated on by this method with resulting cures. In this country the Whitehead is only a relic of the age of the surgical assassin. Surgeons in England still use the "whistle" or "rectal plug." Catgut is used exclusively for the ligatures; neither linen nor silk being employed.

USE OF TERMS

Incidentally it is curious to note the relative frequency in usage of the term piles. Here in America we rather avoid the term as if it were impolite. Be that as it may, it is a more aptly descriptive term than hemorrhoid inasmuch as all hemorrhoids present the symptom of swelling (Latin—pila=swelling or a ball) though not all bleed (Greek—haima=blood+rhoos=flux). The English still cling to the classical spelling of "haemorrhoid" which form is now considered obsolete here.

FISTULA

No one who ever heard Mr. Miles lecture on the subject of fistula could fail to have a clear conception of the nature and variety of fistulæ. The treatment is identical with that in vogue with proctologists here, incision and packing being the procedure in the instance of large fistulæ; excision and suture the procedure in small. The elastic ligature method first devised by Dr. J. Rawson Pennington of Chicago is used occasionally with the modification of using two ligatures instead of one, the object being to prevent any reunion of the severed walls. In conjunction with operations for deep fistulæ, Mr. Miles usually makes four lateral relieving incisions at right angles to the operative incision. The object of this is to increase the surface area of the wound which, according to Mr. Miles, should exceed the combined area of the sides of the wound.

Abscesses about the rectum are believed by Anderson to be due in almost every instance to the perforation and lodgment of a foreign body. He also is of the opinion that in almost all instances if not evacuated promptly they will rupture spontaneously in the posterior wall of the anal canal between the two sphincters.

CANCER

One is very greatly impressed with the work being done on cancer of the rectum and colon and particularly in the conclusions our English friends have arrived at with regard to treatment. They have, like American surgeons, tried all proposed methods of treatment varying from surgery of the conservative type to surgery of a radical type; have tried radium, deep x ray therapy and various other non-operative procedures. Hence, a comparison of their results and their conclusions is most interesting.

Relative to their conclusions as to radium in the treatment of carcinoma of the rectum it may be said that the general sentiment prevailing is not optimistic. Several of the men above mentioned even venture the opinion that the use of radium actually accelerates the growth of the neoplasm. For instance, Mr. Lockhart-Mummery is of the opinion that in rectal carcinomata situated within Others while not holding quite as pessimistic a view, are not at all hopeful on the point of radium therapy. They have come to practically the same conclusions in regard to deep x ray therapy.

SURGERY

In the field of surgery, wide differences of opinion exist as to the most logical procedure to adopt.

Fig. 3.—Holgate Foster Ward in St. Mark's Hospital, London.

the last four or five inches of the anus, perineal excision, combined with a permanent colostomy, is the operation of choice. In this Mr. Anderson concurs. Mr. Swinford Edwards believes that in well defined growths, situated low in the rectum, local extirpation is just as effective. In contrast to this, Mr. Miles is strongly in favor of a combined abdominal perineal excision at one sitting. Sir Charles Gordon-Watson prefers the combined operation in two stages, for high growths; the perineal excision for low growths. All of these men are very greatly impressed with the success of the methods they have chosen and in their hands are, no doubt, satisfactory. The high mortality accompanying the combined one stage operation cannot be denied, while the percentage of recurrences and metastases in the use of perineal excision method is likewise an unfavorable aspect of the situation. They do not use cautery in the excision of rectal carcinomata at all. Regardless of differences of opinion as to the operative method of choice, they all seem agreed upon the point that surgery is, at the present time, the only sure method of treating carcinoma of the rectum. Sir Charles Gordon-Watson does not use either ether or chloroform in his cancer operations but instead uses spinal anesthesia combined with caudal block. Mr. Miles does, however, use general anesthesia. Mr. Lockhart-Mummery uses spinal anesthesia combined with gas oxygen.

VARIOUS METHODS EMPLOYED

To present the arguments advanced by these gentlemen in support of their various methods, the following detail is given.

Mr. Lockhart-Mummery abandoned the use of the abdominoperineal excision in 1913 and at the present time does not use it at all except for high cancers of the rectosigmoidal junction. In the latter instance, he believes it to be the most logical

procedure. The method of perineal excision he believes is much to be preferred in view of the lower operative mortality and the fact that it is applicable to a larger proportion of cases. He has adopted a standardized operation for this type of case consisting of two stages. First a colostomy and the second, which is performed two weeks later, an excision of the rectum and as much of the sigmoid and its mesentery as can be brought down together with the anus and surrounding skin, the contents of the ischiorectal fossæ and parts of the levatores ani. In performing this operation he used spinal anesthesia with the addition of gas oxygen in the case of men and twilight sleep for women. The operation, as outlined, enables the patient to get up in two weeks and to go home in a month. He gives as his operative mortality a little over nine per cent. In regard to recurrence it may be said that in sixty-five cases on whom he performed perineal excision combined with colostomy, thirty were alive and well five years later.

ETIOLOGY OF CANCER INVASION

Mr. Miles is convinced that of the three methods of spread of cancer of the rectum, that is, by direct extension, by way of the blood stream and by way of the lymphatics, that the latter is of the greatest importance. His researches into the anatomical course of the lymphatics lead him to believe that the intramural plexuses of lymphatics do not have very long course along the length of the bowel but are partially separated into the systems, each occupying a short zone in the bowel and each of which give tributaries which drain into the glands lying outside the bowel. In those specimens of cancer of the rectum which he has examined pathologically the anorectal group of lymph glands which comprise ten to twelve glands lying just above the levator ani, are the most important since they were found to be the seat of cancerous metastases even when no other deposits were found. Mr. Miles is much of the opinion that movability of the growth is not a reliable standard by which to judge the amount of spread which had taken place. In support thereof, he showed a specimen where the primary growth had only extended a little over one-half of the circumference of the bowel and yet microscopic examination showed that the cancer cells had already passed through the muscular bowel into the lymphatics. He therefore regards fixation of the growth in the rectum as an indication of a most extensive spread of the cancer and regards it as a great prognostic sign even if complete removal were possible. Since spread has occurred, however, even when a growth is still movable but has extended more than half way round the circumference of the bowel, Mr. Miles contends that the only certain surgical procedure is complete abdominoperineal excision of the rectum and its associated anorectal lymph glands.

Sir Charles Gordon-Watson favors the view held by Mr. Lockhart-Mummery to the extent that while agreeing with Mr. Miles for the theoretical superiority of the abdominoperineal operation, yet he is of the opinion that its practical utility consists in employment for high growths only. He believes that perineal excision of the rectum is the only procedure which is justifiable on clinical and practical grounds.

ECONOMIC CONSIDERATIONS

It would be interesting to note the different economic positions of the specialty in Great Britain as compared to this country. In England, regardless of how great a man's skill is within a specialty, he nevertheless practices general surgery and ofttimes general medicine. Their attitude is that they are all general practitioners and are specially interested in one type of disease. This is, of course, in contrast to our own attitude, where if a man makes any pretense toward a specialty, he is expected to practice this specialty and nothing else. While the latter, or American method, is undoubtedly ideal in many respects, it must be admitted, in justice to our English friends, that their practices in places outside of London are much more limited than ours. Perhaps it would be highly difficult for a man to practice his specialty as strictly as we do here.

THE CHARLATAN PROBLEM

The English appear to have no such problem as the charlatan proctologist. This is perhaps due to the fact that though conservative in manner, they are nevertheless very openminded as to any proposed therapeutic procedure. They do not condemn without trial an innovation, nor do they hastily accept it. They give the new method an impartial consideration, a fair trial and then come to definite conclusions.

In this manner the English remove the fertile field upon which the charlatan thrives, namely, the vague or poorly known therapeutic method. As an instance of this one might take the matter of the injection treatment of hemorrhoids. Because the legitimate proctologists were slow to appraise its value, use and limitations, the charlatan seized upon the method and has since made capital of it; and yet because of its being used extensively by advertising quacks, a large number of legitimate proctologists decry the method. It is quite obvious that the method must be judged on its own merits and not on the basis of the merits of those who use it. It would be just as logical or rather illogical for legitimate proctologists to decry the use of local anesthesia because this same gentry are also using it.

The English have, after an eminently fair consideration of the method, adopted it as one of the methods of treating hemorrhoids. Mr. Anderson, a man of very good standing and eminent abilities, is foremost among those who speak in its favor. Other eminent English proctologists concur in this. In our own country such eminent men as Terrell, Collier F. Martin and Hirschman are thoroughly convinced of its uses in selected cases.

From all that has been said here it may be gathered that by neglecting this method, we have given the advertising quack an advantage that he does not deserve. This has not been done in England, where every proctologist feels entitled to use an injection treatment in cases which he selects as being favorable for its employment.

Practical Therapeutics

VACCINE THERAPY: A REPORT OF THREE CASES

H. L. Frosch, B.S., M.D.
New York

Until recently nothing in medicine was in a more nebulous state than vaccine therapy. It is still in its infancy. It has been exploited to such an extent with the public that a patient expects you to use it. Nevertheless one feels that, as in all things in medicine, the return swing of the pendulum is soon to set in. Before that time arrives, however, vaccine therapy will have reached a surer footing and a more scientific basis. There is great promise in the future for it, especially when such men as A. Wright, A. P. Beddard, W. Leishman have taken the subject in hand and study it scientifically.

By the term vaccine we mean any substance which when injected into the animal body will so incite its mechanism as to produce specific antibodies. This makes the term vaccine synonymous with the word antigen.

In this paper, I propose to report three cases in which vaccine therapy was used. In one the patient was apparently cured while in the other two cases the patients were greatly benefited.

Case I.—A. F., male, fifty-five years of age, had been suffering from emphysema, chronic bronchitis, and myocarditis for thirty years. He coughed a great deal, but that he said did not bother him. What he objected to was the fact that he frequently contracted colds during the wet and winter months which made him miserable. He was well developed but poorly nourished. The head was negative. The chest was large and barrel shaped. The lungs were emphysematous with sonorous and sibilant râles present. The heart was enlarged, no murmurs present, embryocardia. The abdomen was negative.

On account of his frequent colds it was decided to treat him with an autogenous vaccine. He was told to come back during one of his colds, and a throat culture was then made. He was then told to cough and bring up some mucus from the bronchi. A separate culture was made of that. At the end of twenty-four hours a growth of streptococcus anhemolyticus and pneumococcus was present. A vaccine was made from these organisms.

He received twelve injections starting with five millions doubling each succeeding dose every five days. Following the fourth injection he had a focal reaction, consequently the next injection was given after a ten day interval. He said that he had fewer colds than any previous winter for the past ten years. The following winter he received no vaccine and he again had frequent colds.

Case II.—L. K., female, forty-eight years of age, had been suffering from emphysema and chronic bronchitis for eight years. She complained mostly of frequent colds which she contracted during the rainy and winter months. She was a well developed, well nourished, white female, with a large barrel-shaped chest and emphysematous lungs with sonorous and sibilant râles present. The rest of the examination was negative. It was decided to use a vaccine. A throat culture and sputum brought up from the bronchi were used. At the end of twenty-four hours, a streptococcus anhemolyticus and pneumococcus were obtained. She also received twelve injections at five day intervals, as in Case I. She was so well satisfied with the result that she came back the past two winters for vaccine treatment.

Case III.—M. F., male, twenty-seven years of age, a barber by trade, began to suffer three years ago from weekly attacks of what was then diagnosed as asthma. He was told by his physician to go into another trade. After a great deal of suffering he obeyed, with the result that the attacks disappeared. Six months ago on account of his finances he was forced to resume his previous trade. Within two weeks he had a recurrence of his old attacks.

Physical examination revealed nothing. He had no asthma at the time and his lungs showed no evidence of bronchitis or emphysema. The history, however, was very definite. The patient was then told to bring samples of hair and dandruff from as many customers as he saw in two weeks. A sample of this mixture was then put in a twenty per cent. solution of alcohol with normal saline as the diluent for the alcohol. This was kept for five days with an occasional thorough shaking. At the end of that time it was filtered. A drop of the filtrate on the patient's forearm and a superficial scratch through it produced within a half hour a typical wheal surrounded by a zone of erythema. This dispelled all doubt as to the diagnosis.

The crude filtrate was now transferred to a sterile test tube two drops of lysol added to it, thoroughly shaken and allowed to stand for a few days. At the end of that time a loopful of the solution planted on a gluocose serum agar slant showed no growth at the end of twenty-four hours. This solution was now dissolved in normal saline in strengths of one half, one quarter, down to one sixty-fourth of its original strength. A drop from each dilution on the patient's forearm and a scratch made through each gave the following results: one half strength, ++++; one quarter strength, +++; one eighth strength, ++; one sixteenth strength, +; one thirty-second strength, faint wheal but definite; one sixty-fourth strength?

The patient was then given a course of twelve injections at five day intervals beginning with a one half c. c. of one sixty-fourth strength, then one c. c. of that; then a one half c. c. of the next strength and then one c. c. of that, and so on. After the fourth injection he complained of a slight headache, running nose, and a heavy feeling in his chest for twelve hours. After the seventh injection he had a definite attack of asthma which compelled him to go to bed for two days, and it was decided to put off the next injection for two weeks. After that he received the rest of the treatment without any untoward effect except an occasional slight heaviness in the chest.

During the treatment he did not work. He was now told to go back to his shop. He has been free from any attacks now for two months.

THERAPY OF THE NONSPECIFIC PROTEIN REACTION*

Observations Based on the Intramuscular Injection of Venom Protein (Crotalin) Solution in Six Hundred Cases

Ralph H. Spangler, A.M., M.D.,
Philadelphia

(*Concluded from page* 441)

In closing, I want to refer to dysfunctions of the endocrine glands and menstrual irregularities in the female. These conditions are frequently encountered in a series of epileptic patients. The adjuvant effect of venom protein injections by its nonspecific action is stimulating glandular and general plasma activation and by altering the permeability of cell walls often enhances the oral use of dried extracts of the glands of internal secretion; to illustrate:

Case II.—In October, 1918, a girl, twenty-one years old, just starting her senior year at college, consulted me with reference to a convulsive seizure which occurred while at college. History briefly as follows: She was an eight months baby born with instruments; breast and bottle fed; no spasms in infancy. She had had measles and scarlet fever as a child. Menstruation was established at fifteen years which was irregular for two years. First convulsion occurred at her seventeenth year. Periods continued at two to three month intervals and second convulsion occurred at nineteenth year. After this second seizure periods were absent for two years or until September 20, 1918. Two days after this period influenza developed in mild form; a week later she had a third convulsion. A gynecological examination by Dr. George Erety Shoemaker showed no growth or abnormality of formation, but a rather undersized uterus in good condition. He recommended corpus luteum and added to his report that "it sounds like true epilepsy." The patient returned to college and for ten weeks took four lutein tablets daily. No convulsion occurred but there were no menstrual periods. I then began venom protein injections once a week. After the third injection of one two hundredth grain, a menstrual period appeared. The lutein tablets were continued for two weeks out of each month with a venom protein injection once a week, and a period occurred each month during the year 1919. Her periods have continued regular and it is now five years since the last convulsion, and four years since treatment was stopped.

Case III.—Another patient who came under my care on February 7, 1919, was a nine year old boy, who at two and a half years of age started having fainting spells and momentary periods of unconsciousness, diagnosed as petit mal. These continued until his sixth year when convulsive seizures began to occur at one to two week intervals. Under bromides and various glandular combinations the longest interval between major attacks was forty-three days but the petit mal grew more frequent. He had many lapses in a day and at times eight or ten in an hour. Luminal was given for several months but the mother reports that both forms of attacks continued and that mentally the boy became much excited at times. She was advised that a form of insanity was developing and that for her own safety the boy should be placed in an institution.

Venom protein injections were started at weekly intervals. All sedative medication was withdrawn. During the first four months five grand mal attacks occurred but the petit mal continued and rarely a day passed without at least one momentary lapse being noted. After receiving venom protein injections for four months, one grain of thyroid substance (equal to five grains of the fresh gland) by mouth was added every twenty-four hours. By the sixth month the petit mal had stopped. Since starting the thyroid extract he has had but two convulsions, the first on February 14, 1920, and the second on July 16, 1920. He has now gone three years and nine months without any form of seizure and no intercurrent illness has developed. He is fourteen years old, attends school regularly, is developing normally and secondary sex characteristics and has gained fifteen pounds in weight in the last six months. For the past two years one two hundredth grain of venom protein at two week intervals has been given but there has been no thyroid administered for fifteen months.

SUMMARY AND CONCLUSIONS

1. During the past decade the value of nonspecific biological reactions following various protein injections and the benefit of nonspecific resistance to the human organism has become gradually recognized.

2. The mechanism of the nonspecific reaction is generally conceded to include: a. General cell stimulation—"plasma activation." b. Altered permeability of cell and vessel walls. c. Stimulation of the hematopoietic system.

3. The use of venom protein (crotalin) solution is one of the earlier recorded instances of the employment of a nonspecific protein for definite therapeutic purposes.

4. Snake venom is a chemically defined protein which is physiologically standardized by the reptile itself. Its action when tested in animals and the human shows that it: a. Stimulates general cell metabolism. b. Alters the permeability of the blood-vessel walls. c. Produces a selective stimulation of the hematopoietic system and lengthens the clotting time of the blood.

5. Venom protein injections do not produce a general leucocytosis but they do alter the proportional relation of the cells in the differential count with a tendency to an increase of the eosinophile elements.

6. The study of the differential leucocyte count with special reference to the percentage of eosinophiles produced following venom protein injections,

*Read before the Philadelphia County Medical Society, April 9, 1924.

has proven a satisfactory method for regulating the strength of dose and frequency of administration.

7. The practical advantage of using venom protein to produce a nonspecific reaction for therapeutic purposes is shown by the fact that when given intramuscularly, in properly regulated doses, it is harmless, producing no severe local reaction; and that systematically it is followed by no chill, fever, gastric disturbances or vasomotor paralysis.

8. Clinically my experience with the use of venom protein in cases of epilepsy has shown some striking result in the relief or modification of convulsive and mental phenomena. Coincidentally I have observed the favorable effect of venom protein injections on patients' general metabolism, as shown by gain in weight, increase in the percentage of hemoglobin and the number of erythrocytes, and the patients' feeling of well being. The general resisting powers of patients was often found to be increased, as they rarely contracted or developed intercurrent diseases.

9. Of special interest has been the adjuvant action of venom protein injections when used in conjunction with drugs—bromide or luminal in epilepsy; iodides, salicylates, etc., in indicated conditions. Moreover, venom protein used in conjunction with the glands of internal secretion by its plasma and glandular activation, enhances endocrine therapy.

10. Chemically, physiologically and therapeutically venom protein (crotalin) solution seems to meet satisfactorily the requirements of a biological agent to produce nonspecific resistance.

Antityphoid Vaccination by the Mouth.—C. Achard and S. Bloch (*Bulletin de l'Académie de médecine,* April 29, 1924) note that, in view of the recent reports by Vaillant, Besredka and Gauthier, it appears that epidemics of the typhoid diseases can be checked by vaccination by the mouth. There remains to be ascertained, however, whether all persons who have ingested the vaccine are thoroughly immunized and whether their immunity is likely to be lasting. One of the authors' patients had ingested the prescribed twenty-eight keratin coated pills of vaccine in seven days, yet contracted typhoid fever three and a half months later. They ascribe the absence of immunity in this case to lack of absorption of the vaccine through the mucous membrane, the pills ingested not being such as to insure absorption. To be certain that immunity has been established by the oral use of vaccine in any given case, an actual demonstration of the antibodies in the blood would seem desirable. The authors found that upon doubling the dosage of vaccine and giving bile, magnesium sulphate or calomel in addition, the agglutination reaction failed to appear, but the complement fixation test for typhoid became positive at varying intervals after the ingestion of vaccine. It would seem that where such a positive test is obtained, absorption of the vaccine may be asserted to have taken place. A means of control of the success of antityphoid vaccination by the mouth in any given case is thus afforded. While this procedure, requiring the collection of blood specimens for the complement fixation tests, sacrifices the relative simplicity of vaccination by the mouth as compared to vaccination by hypodermic injection, the procedure may nevertheless seem preferable to patients as well as some physicians on account of its harmlessness and the absence of the reactions following hypodermic vaccination. The procedure is also applicable where for various reasons, such as organic disease in the individual, exposure of the latter to the risk of the reactions sometimes following vaccine injections is deemed inadvisable. The completeness and duration of the immunity afforded by oral vaccination can be determined only after several years of observations, as was the case in the demonstration of the prolonged efficacy of vaccination by hypodermic injection.

Serum Treatment of Puerperal Sepsis.—Harold Bailey (*American Journal of Obstetrics and Gynecology,* June, 1924), having made clinical use of a polyvalent antistreptococcus serum prepared by Huntoon from many sources of streptococcus infection in man, advocates the administration of 100 mils of serum in the presence of a puerperal fever continuing through a second twenty-four hours. This should be done at the time the blood and uterine cultures are taken, and after proper desensitization tests. A number of the patients develop serum sickness, generally after forty-eight hours, but no serious effects need be feared. The intense itching of serum urticaria can be temporarily relieved by small doses of adrenalin. Most patients showed a rise of temperature and pulse rate after serum injection, and many had a marked chill. The serum should preferably be given at a time when the temperature is at its low point for the day. In the taking of intrauterine cultures the cervix is exposed with a speculum, grasped with sponge forceps, wiped with 3.5 per cent. iodine, and a cannula then inserted into the uterus. A much smaller tube with a suction bulb is then inserted through the cannula without touching its edges, and the discharge sucked into it by releasing the pressure on the bulb. The second tube is then removed through the first. With this method the writer never failed to obtain a pure culture. No local treatment was given. The patients were exposed to the outdoor temperature on a balcony, but with protection from direct draughts. Examinations by the vagina or rectum were reduced to a minimum. Where there is a small amount of exudate in the parametrium, walled off by a leucocytic barrier, a bimanual palpation may be sufficient to destroy the protective area. The serum seemed to have a definite tendency to localize the disease by the production of a parametritis.

Historical Medicine

Historical Evolution of the Doctrine of Crises in Disease*

CHARLES GREEN CUMSTON, M.D.,
Geneva, Switzerland

(*Concluded from page* 444)

However, already in the fifteenth century, a physician perhaps better known by his famous poem *Syphilis,* Fracastor, attempted to react against astrologers and against those whom he called *quasi fascinationibus astrologrum lustrati.* He endeavored to substitute a new doctrine for the then accepted theories, and to explain crises by movements of the humours: bile, phlegm, melancholy. In reality, it was natural to admit that the humours undergo changes in most diseases. The peccant humours must go through the necessary process of coction in order that nature may rid herself of them. Now, since the coction of melancholy required four days, it necessarily follows that the crisis should take place from four to five days.

Fracastor's doctrine recruited few followers; however, those physicians who adopted it, although admitting critical days according to Galen's teachings, gave as causes for crises and critical days, the diversity of humors that most undergo coction, and, in their eclecticism, they also added the different temperaments as well as lunar action.

The great literary movement of the Renaissance resulted in the fact that physicians being more learned in ancient languages, especially Greek, read the original manuscript texts of Hippocrates and Galen, and abandoned the Islamic translations and versions. The Hippocratic-Galenic doctrines were revived in all their purity.

The reaction was not long in making itself felt, and Paracelsus (1493-1541) inaugurated his lectures on medicine at Bäle by publicly casting the works of Galen and Avicenna into the flames. But although Paracelsus accepted the doctrine of crises to a certain extent only, Van Helmont (1577-1644) denied it absolutely: *"Boni ergo et fidelis medici est negligere crises."* He could not accept the comparison made between crises and a struggle: *"Ita nec morbus repugnat naturae duru maturatur, non magis, quam ovum, dum fovetur, cum fovente gallina pugnat."*

It was at this time (1628) that Harvey appeared upon the scene—an epoch when Vesalius, Cesalpinus, Fallopius, and Fabricus ab Acquapendente were building up an exact anatomical knowledge—and laid the first foundations of experimental physiology. But it was not long before the importance of experimentation became overrated and, as in the days of the empiricists of Alexandria, Chirac (3) (1650-1732), with his turbulent polypharmacy, merely recorded—without reasoning—the phenomena that he accidentally provoked. He had the pretension of directing the movements of living bodies, and his disciple Fizes (1690-1765) tells us: *"Naturam errantem dirigimus et collabentem sustinemus, non otiosi crisium spectatores."* (4)

And must not Hoffmann (1660-1742), with his ideas on spasm and atony of the tissues, be compared with the Methodists? It is certainly true that his doctrine is reasoned and wise and although disputing critical days, he accepted crises, applying to them the explanations offered by the Solidists and not believing that the expectant treatment of Hippocrates was the one to follow. And with Hoffmann's theories one must compare the sthenic and asthenic diseases of Brown (1735-1788).

Reil (1759-1813) was another opponent of the Hippocratic doctrines, and from the special point of view of crises a summary of his opinions will be found in a dissertation (1801) upheld by Gruetzbach (5), one of Hebenstreit's students. Peccant matter does not exist; disease corresponds to lesions of the solids. Hence crises are not the expulsions of this matter, and the cause of cessation of fever. Critical evacuations are merely the normal reestablishment of the functions which have been disturbed during the evolution of the pathological state.

Such are the principal physicians who from the Renaissance to the nineteenth century were opposed to the humoural and vitalistic doctrines of Hippocrates, although often, it is true, judged according to Galen's appreciation, when their writings are carefully examined, it at once becomes evident that their systems are closely related to those of the ancient sects, while on the other hand they lead us step by step to those ideas first advanced by Broussais.

But there were others who, throughout the fleeting cenuries, upheld the great doctrine of *vis medicatrix naturæ.* For them disease was an entity, evolving up to the crisis, and all measures of treatment were to be directed to this end, never to upset it.

Among these men I would mention Dulaurens (6), physician to King Henry IV of France, Lazare Riviere (1589-1655) (7), and if one desires prominent medical personalities of the seventeenth century, I would first of all mention Sydenham among the convinced defenders of hippocratic naturalism. Is this not also the foundation of Sthal's (1660-1734) animism, in which expectation, while awaiting the crisis, triumphs? The vital force, whose nature Hippocrates does not specify, is called the soul by Sthal; it is this soul which struggles against the morbific principle and "it is precisely by means of febrile attacks, as well as the legitimate and proportioned effects of the attack, that man is integrally delivered from fevers by the spontaneous power of nature." (8).

Baglivi (1668-1707) opposed the exaggerations of the iatrochemists and likewise repulsed the humoral pathology of the Galenists, and attempted to bring back the science of medicine to observation and the pure Hippocratic doctrine. Although it may not be as easy to verify crises as is usually supposed, Baglivi maintained that this was due to the fact that their manifestations were disturbed by the multitude of

drugs prescribed and he points out that to recognize them one should observe disease in peasants who do not consult physicians. He also enjoins young physicians to study crises and critical days.

Boerhaave (1668-1738) whose influence was very great during a certain epoch, was highly in favor of the doctrines of crises and was the means of causing Van Swieten (1700-1772) to entertain his views. In speaking of Van Helmont, the latter expresses himself as follows: *"Jactabat enim se posse nascentes morbos in ipsis suis incurabulis quasi suffocare antequam adlescerent; et medici nomine indignos esse qui hoc efficere non possent. Verum tot et tanta promittere facillimum est, exsequi autem difficillimum."* (9) This was written at about the same time when the Spanish physician, Solano (1685-1738) questioned whether careful observation of the pulse would not be the means of foreseeing the advent of crises, thus establishing a reasoned prognosis according to the teachings of Hippocrates.

As to the critical days, they were beginning to be less favorably regarded. De Haen (1704-1776) endeavored to collect all the scattered facts concerning the subject related by Hippocrates, while Cullen (1712-1790) admitted the prognostic value of the third, fifth, seventh, ninth, eleventh, fourteenth, seventeenth, and twentieth days. In 1751, the Academy of Dijon offered a prize for the best essay deciding whether critical days were the same in the climates of France as in those where Hippocrates observed them, and Aymen, whose work I have already referred to, solved the problem in the affirmative, and maintained their practical value.

In 1753, Bordeu (10) published an important historical work on crises and critical days. In reality, this remarkable clinician, like Solano, set out to study those changes of the pulse susceptible of foretelling the advent of crises, and he first of all established the fact that observations confirmed the existence of critical phenomena, but destroyed the doctrines of critical days.

Now it was at this epoch that the physiological and experimental methods were beginning to bear fruit. The marvelous had progressively been reduced to nothing; the part played by hypothesis was slowly but surely on the decline, and thus we come to the end of the eighteenth and the commencement of the nineteenth centuries; yet the same dissensions continued. Nobody now seriously considered the doctrine of the indicatory and critical days, and it merely is a matter of historical curiosity to mention a *mémoire* published by Bricheteau as late as 1848, in which he still clings to their importance. From this time on nobody will be found to deny the critical phenomena in acute disease, but interpretations will differ.

In the first place, Pinel, a staunch believer in the essentiality of fevers, whose thesis appeared in 1796, upholding this doctrine, was followed five years later (1801) by Broussais, the most advanced champion of the opposite doctrines and who passed the remainder of his life in attempting to demonstrate that invariably irritation and phlegmasy are in play. Consequently for him, crises are irritations, sympathetically produced at some sitant part, hence acting favorably like a blister, a bloodletting, or a purge. For a time Broussais's doctrines were practically accepted everywhere, but about 1835 they began to pale. Already in 1826 Bousquet maintained that crises were not revulsives, because in those diseases where they took place were not always inflammatory processes, and he also pointed out that the physician should be able to produce a crisis at will were this the case, when in reality he is powerless to do so. To bring about crises nature possesses procedures unknown to man; she has fixed times for action and organs which she prefers, and produces them according to laws that still remain to be discovered.

However, the works on general pathology of this epoch reveal the antihippocratic and antihumoral tendencies of the most authoritative representatives of the Paris School. Chomel said that the doctrine of crises could not be denied; a crisis merely is a remarkable change for better or worse arising during a disease, but he refuses to consider the relationship existing between this change and critical phenomena. Are the latter the cause or effect? To this question Chomel replies that according to circumstances they are either one or the other. Many other distinguished names could be mentioned; but time does not permit. Let it be said, however, that they perpetuated the discord and that this hesitancy in respect to the hippocratic doctrine was likewise rampant in the Faculty of Medicine of Strasbourg.

At the venerable Faculty of Montpellier, the Hippocratic doctrines have always been accepted in all their primal simplicity. Disease has always been considered as an entity, a corrupt principle against which the forces of the human organism struggled in common effort. And today, with all we have gleaned from the progress of biological chemistry and bacteriology, are we not logically compelled to accept a conception of disease similar to that conceived by Hippocrates?

The doctrine of critical days is forever gone, but the doctrine of crises in acute morbid processes is as true today as when Hippocrates developed it, namely four hundred years B. C.

The Taoist Pharmacopœia.—This is restricted to mineral preparations. They have not descended to devising concoctions, as in other primitive schools of medicine, so disgusting to the offending demons that they would flee in terror. The priests sometimes try to distill mercury. When the preparation has been successfully distilled nine times, the resulting substance is called the elixir of life. The panacea for all ills is to make the mind an absolute blank, and to remain motionless in accordance with the master's teachings.

Obstetrical Images

ALFRED ELA
Boston, Mass.

Close relations between obstetrics and religion have been illustrated (5) so recently that no mention need be made here. Such relations were represented in an extant picture (4) of about thirty thousand years ago, and an almost continuous chain of similar representations remain so far as they have not been wilfully destroyed in recent centuries. The latest find (8) is of over six thousand years ago, in Crete. A female clay idol of squatting type, evidently of the Neolithic era, exemplifies the type on the neighboring mainland of Asia. What had there hitherto been found cannot be looked up by me, even in my notes, as I am blind and without clerical aid; I can merely adduce a few parallels elsewhere, as these chance to stick in memory, viz.:

The squatting position, the abandonment of which and of its equivalents, may be largely responsible for childbirth among us having become a pathological process rather than a physiological one, is amply illustrated in a book (6) which rapidly passed through several editions.

The French, amplified, translation (7) has on page 336 a picture of a West African pantheon of forty years ago, showing, among other images, one of a squatting, parturient goddess, the head of the infant being all yet in evidence.

Conventionalized, squatting, images (1, 2) used by West Indians at time of discovery by the Spaniards, still survive in considerable numbers because the images were small; comparison of these with similar ones on the continent of America were prevented by the discoverer's lamentable death.

The purpose of this article is two fold, viz.: to invite any qualified person interested in the arts (3), obstetrics and religion to make use of my notes, which will be freely and gladly given; to call more general attention to the Cretan article (8), wherein the discoverer of that important but forgotten civilization, has reported his last summer's explorations.

Contributors to the Science of Medicine

Rudolf Virchow

When Rudolf Virchow died on September 5, 1902, in Berlin in his eighty-first year, science as a whole had one of the greatest losses it has ever sustained, so many sided were the attainments and learning of this great man, whose work was notable in medicine, biology, anthropology, literature, scholarship, and statesmanship. The medical press in particular lamented Virchow's death, and the journals of 1902 are full of eulogies, biographical sketches, and accounts of his work. The *Philadelphia Medical Journal,* for instance, followed in its columns the happenings of the last several months of the great scientist's life from the time when his health began to fail and he was taken to Carlsbad for the cure, to his death and municipal funeral, when the whole city of Berlin went into mourning for his death. The funeral services were held in the city hall, where the body lay in state in the assembly rooms of the magistracy. These chambers and the adjoining lobbies were literally choked with a profusion of flowers from the scientific societies of all nations and from personal friends and colleagues. American physicians in Berlin sent a magnificent wreath expressing the respect and admiration of America for Virchow's work in pathology. The rooms were crowded with the great men of all nations, including many royal personages. The funeral cortege was so long that it took more than an hour for it to pass. Virchow was buried in St. Matthew's Cemetery.

His birthplace was Schievelbein in Pomerania, and the date of his birth was October 13, 1821. His family was of humble origin. After attending the gymnasium and the Friedrich Wilhelm Institute, he went to the University of Berlin, whence he was graduated in 1843. His thesis was entitled *De Rheumatic Praesertim Corneae.* When only twenty-four years of age he was appointed assistant prosector to Froriep of the Charité, succeeding him as prosector the following year. In this position he directed the whole anatomical routine of that great institution. In 1847 he was made a regular lecturer in the University of Berlin, and founded with Reinhardt the *Archiv für*

pathologische Anatomie und Physiologie und für klinische Medizin, which later was given his name. In 1848 the government sent him to Silesia to study an epidemic of typhus among handloom weavers. His report was so complete and scholarly, and showed such penetrating insight both from a scientific and from a political point of view, that it probably helped lead to his being offered membership in the Prussian Lower House. Since he was only twenty-seven he would not accept the post. At this time he was editor of a medicopolitical paper called *Medizinische Reform.* In 1849 he was discharged from his prosectorship because of political affiliations unpleasing to the government, but so many other positions, both educational and literary, were opened to him that his dismissal hardly affected his career. During his lifetime he was editor of several of the leading medical and scientific publications of Germany, and occupied chairs in a number of the universities.

In 1859 the government of Norway summoned him to make a study of leprosy in that country. In the same year he was made a member of the Berlin Municipal Council, a post which he filled for more than forty years. In 1802 he became a member of the Prussian Lower House, where he was one of the founders of the progressive radical party, and as its leader so antagonized the imperial government that Bismarck challenged him to a duel. For several years he was a member of the German Reichstag, always on the side of the people, and in 1866 became a director of the *Berliner Hilfsverein für die Armee im Felde.* Through his own personal efforts, the first Prussian ambulance corps was organized, and the hospital of the Tempelhof Field, Berlin, erected. He was influential in the erection of many other German hospitals and scientific institutions, in bringing about the adoption of the Berlin sewerage plan through a system of canals, and new regulations concerning animal diseases, slaughter houses, and fisheries. Virchow's great renown throughout the civilized world was shown by the international celebration of his eightieth birthday in 1901. Many of the largest cities of many countries had ceremonies in his honor, and in Berlin a great meeting was held, at which the German physicians presented him with a large sum to add to the endowment of the Virchow Institute; the Emperor gave him a gold medal testifying to his scientific achievements; another gold medal came from the King of Italy; and many universities and medical and scientific societies made him an honorary member and conferred degrees upon him. Special Virchow numbers of medical journals were published, and the new Berlin municipal hospital was named the Virchow Krankenhaus.

Virchow's fame in medicine rests chiefly upon his work in pathology. His great work was on cellular pathology. This became known to Americans through the translation of Frank Chane. He discovered the selfpropagating power of the animal cell. His work is based on the theory that "man is a cell state, in which every cell represents citizenship, the tissues, muscles and bones representing different layers of society. Disease is merely a conflict in this state between citizens, caused by changes wrought by outside action." He was the first to use the term mycosis. His work fills more than 125 large volumes and a thousand pamphlets. Virchow did not establish a school; he was too broadminded and farseeing for that. He has been compared to John Hunter in that both, in pathological anatomy, represented the pure Baconian type of scientist.

As one of the leaders of the Prussian Radical Party he of course often incurred the displeasure and opposition of the Imperial government, yet he continued to hold for the greater part of his life important political positions, and was able to bring about many legislative reforms, especially in the field of public health. Among these were the German vaccination laws and those for food inspection and suppression of epidemic diseases.

As an anthropologist Virchow was especially interested in the races of the Pacific islands, and was the author of several monographs on race similarities and differentiation. As an archeologist, he studied on the ground the remains of the civilizations of Greece, Asia Minor, and Egypt, traveling with the famous Schliemann and often taking part himself in the excavations.

Dr. Joseph McFarland, writing in the *Philadelphia Medical Journal* for September 13, 1922, gives some interesting personal reminiscences of Virchow, with whom he was associated in work for a few months. Dr. McFarland says that Virchow "acted less like a great man than almost any person I have ever known. He had little place in his own thoughts." He was small, but with broad shoulders, and his face was Semitic rather than Teutonic in type. His conversation was rather rambling, and his delivery as a lecturer monotonous and tiresome. "He paid the most minute attention to what one might regard as unimportant details, and no doubt much of his success in life depended upon this care. A friend with whom I once walked through the Institute remarked that a great man should not sit calmly before a table covered with jars and waste time pasting labels upon them. It was, however, in all probability one of those details the importance of which he grasped, and which helped to make the museum of the Institute great. . . . Correct and careful himself, he required those with whom he came in contact to be so. I have seen him stop in the midst of a lecture to caution a student not to tilt a jar lest he injure the specimen it contained. His lectures were excellent in substance, but tiresome from the monotony of his delivery. There was no eloquence, no dramatic effect. Inattention, however, was intolerable to him. 'Herr, sind sie krank?' he one day asked a student who sat before him with his head resting on his hands, his eyes closed, and his thoughts wandering far from the subject at hand. His perceptions were very keen. Things seemed plain to him. He classified facts readily and saw the subtle connections between related phenomena. 'Professor,' said a student, 'I wish to do some experiments on inflammation.' 'Inflammation!' said the old man, his eyes kindling. 'Inflammation is only a conception, an aggregation of phenomena; you cannot experiment on inflammation.'

"His keen appreciation of the value of results derived from careful experimentation, and his own industry, perseverance and patience gave him a horror of unfinished work. I was forced to leave Berlin in the midst of a research begun in his laboratory,

and under his direction. As I made my farewell visit, the old man grasped me by the hand, but, though his greeting was friendly, he gave me the impression that I should not regret my departure because of severed acquaintances so much as because my *Arbeit* was not finished. Since then I have always had a disagreeable feeling when I had unfinished work on hand. Brief through my acquaintance was, I remember Virchow as a broadminded, wholesouled man, generous toward all, possessed of a remarkable keenness of intelligence, careful attention to minutiæ, unlimited patience, determined perseverance, and a vast capacity for work."

Herodotus as a Medical Writer.—Warren R. Dawson, F.R.S., in a letter to the editor of the *Annals of Medical History* (September, 1924) writes that in an exhaustive study of the ancient Egyptian medical papyri, it was necessary to read the works of ancient medical writers of other countries, and that among these Herodotus yielded a large and interesting crop of statements on medical subjects. Illness and disease are nearly always attributed to divine displeasure afflicting the transgressors through evil spirits, but Herodotus contradicts this statement made by nearly all the papyri and writes that the Egyptians believed that all the diseases to which they were subject were caused by the food they ate. He informs us that they "purge themselves every month, three days successively, seeking to preserve health by emetics and clysters." Herodotus states that all their physicians were specialists, but from the medical papyri it would seem that they were general practitioners. The Babylonians are said to have had no doctors but to have brought their sick into the market place so that passersby who had been similarly afflicted might advise as to treatment. The Persians appear to have had some medical skill. An enemy who had fought bravely and been seriously wounded was rescued because of his great valor by the Persians and had his wounds treated with myrrh and bound with flaxen cloths. Him they treated with the greatest honor, but the other prisoners had the rank of slaves. The Persians isolated all persons with leprosy and scrofula. They drove away white doves, believing them to be similarly afflicted.

Herodotus believed that the dwellers in the Nile valley became black through exposure to extreme heat. Several cases of mental disorders are mentioned. Cambyses suffered from infancy from the "sacred disease" (epilepsy); "in that case it was not at all surprising that when his body was so diseased, his mind should not be sound." Another prominent personage was out of his mind and had to be confined in a dungeon. The crew of a trireme was seized with madness—the venegance of a god because his statues were violated. Cleomenes's "madness" is attributed to his habit of drinking unmixed wine. Two cases of blindness are mentioned, one the result of a vision, and the other of divine punishment for an insult to the river Nile. Croesus had a son who was dumb, and, after all remedies had been tried in vain, the Delphic oracle was approached. The reply was to the effect that it would be an evil day upon which his son should first speak. He did so when a Persian was advancing to kill his father, and so saved the latter's life. The Carians in attempting to dig through an isthmus in order to convert it into an island were receiving severe injuries to their eyes from the stone cutting. They consulted the oracle, which replied that if Zeus had wished the land to be an island, he would have made it so. The Carians forthwith abandoned their undertaking and were captured!

Of anatomy practically nothing is found in Herodotus except what is contained in his well known description of the Egyptian method of embalming. Mention is made of opening the body of a boy killed with an arrow by Cambyses in order to ascertain what portion of the body the weapon had penetrated. It was found in the heart. Mention is also made of the finding of a skull without sutures, and of a jaw in which the teeth had all coalesced into a single bone.

We are told of a father who refused to believe his own paternity because his son was born before ten months had expired. His wife, however, knew that women often bear children after seven or nine months, and declared that her son was a seven months' child.

An interesting case is described of a prisoner who to escape torture cut off most of his foot in order to free it from a chain, dug a hole through the wall, eluded the sentinels, and made his escape through traveling at night and hiding in the daytime.

The Librarian of the First French Public Library a Physician.—Dr. J. W. Courtney, in an interesting article on Gabriel Naudé, M.D. (*Annals of Medical History,* September, 1924) tells us that according to biographical records no woman ever aroused in Naudé a tender emotion. "In his modest dwelling at Chantilly he managed to tolerate the presence of a female cook because, as he tells us, he sometimes desisted long enough from his studies to go to the *manger*. However, in spite of this outstanding misogynistic trait, he constantly refers to the Mazarin library as his daughter. Snugly sheltered within the walls of Rome, he had written his infamous *Coups d'état* which comprises a vindication of the St. Bartholomew massacre, a document so perfectly inhuman and revolting that the reader recoils from it in horror, wondering what manner of monster mind spawned a thing so unspeakable. And wonder waxes when one finds that it was the same mind which conceived the subtly delicate idea of contriving a retired entrance, royal in its exclusiveness, through which supersensitive, out at elbows seekers after knowledge, garret rats from the 'left bank' or lodgers under the Pont Neuf, might make their way direct to the Mazarin volumes without encountering the disdainful glances and humiliating innuendos of the Cardinal's ornate flunkies and other equally offensive servitors. For several years prior to 1648 the entrance in question was put to use by favored scholars. Naudé tells with pardonable pride that he often saw upwards of a hundred of them at a time, all immersed in pages of his precious volumes." Thus it was Gabriel Naudé, M.D., famous physician of his time and honored librarian of the "titled crook," Cardinal Mazarin, who opened the doors of the first public library in France in the year 1652.

Editorial Articles

WHITHER ARE WE TENDING?

To the careful observer of world affairs, it is all too apparent that all mankind is in revolution—revolution which is an evolutionary expansion away from the established order of things—and it is a wise man indeed who can foretell the goal which will be reached. This is what has happened whenever man has begun an Hegira. It is doubtful if those who lived at the time of the Reformation realized even dimly the extent to which a desire for religious freedom would lead the world and those who heard that first shot at Concord could not foresee the distances in time and space to which its reverberations would reach. Another shot, that of Sarajevo, set the whole world on fire, altered the map of Europe, changed the economic basis of the nations and set loose upon the earth a desire for freedom which on the one hand would abrogate moral restraint and on the other enacted the Eighteenth Amendment and created Fascicism.

The Bolsheviks and Soviets cry for greater liberty, Mussolini pronounces dead the virgin goddess of Liberty, the conservative demands a return to Victorian prudery, reformers urge greater public expenditure for uplift work, reactionaries long for the days of individualism when every man fended for himself. The industrial face of the world has been changed just as the amateur mapmakers of Versailles changed the geography of Europe and left a dozen danger places, any one of which would even now be kindling the fires of war were it not for the restraint of economic pressure.

We of the medical profession are part and parcel of this revolution; we are so entangled in it that we have lost our sense of orientation; we are changing rapidly, but do we stop to consider where this change is leading us? Do we endeavor to shape our course in a desirable direction?

Aside from the changes which are concomitant upon the general change which society is undergoing, there are certain seeds of mutation within ourselves. The increase in hospital practice, the extension of the dispensary movement, the introduction of the scientific refinements of treatment, group practice, the increased efforts in the direction of public health, industrial hygiene and the health education of the general public are altering the entire outlook of medicine. The sanitary profession has reduced the communicable diseases to a point where considerable inroads have been made on the income of the general practitioner, specialism has divided and subdivided the fields of practice until the sections sometimes seem to have been made by a microtome; the cost of illness has risen to a point where only the very rich and the poor can hope for adequate treatment. The doctor himself has in a measure forsaken the art of medicine for the science of medicine, perhaps for the business of medicine; frequently, the sick man ceases to be a patient and becomes a case, a vehicle for an interesting disease. The public, especially the great middle class which is neither rich nor poor but is none the less the meat in the community sandwich, is growing restive under the high cost of medical and surgical treatment and is seeking relief in the realm of quackery, isms and pathies. Between the specialist on the one hand and the irregular on the other, the general practitioner is subjected to an economic pressure which is killing off this splendid body of medical men. The great god Gouge is slaying his worshipers; the public is getting doctor shy.

What is the answer? Is it state medicine? Is it a limitation of specialists? Is it group practice? Is it the medical education only of those who are not dependent on their fees for a livelihood? Is it the abolition of commercialism from medical practice? Is it the adoption of more stringent guild methods? These are questions which the leaders of medical thought should answer. As it is, we are being carried somewhere, into some uncharted sea without pilot and the helm adrift.

THE GREAT PLAGUE OF LONDON

If testimony is required with regard to the efficacy of sanitary measures carried out properly and on a big scale, no more convincing evidence can be found than a history of the various epidemics of plague which attacked London some hundreds of years ago. Our knowledge hitherto of this subject has been gathered mainly from Defoe's *Journal of the Plague Year*. Of course, Defoe was one of the most vivid descriptive writers that ever lived, a genius indeed in this respect. However, more than most men of genius Defoe possessed an almost untrammeled imagination.

Robinson Crusoe is the outstanding example of this conspicuous faculty of making the inventions of his imagination read like facts. But this gift may be detected in all his works whether they were published as fiction or fact. Therefore Defoe's account of the plague while a book to be read as a wonderful tale, may be regarded with some doubt as a faithful

record of true happenings. Also his book was written nearly fifty years after the Great Plague.

Defoe's immortal work will always be read for its literary qualities and for its striking descriptive powers, but a book published recently by the Bodley Head Press, London, and written by Mr. Walter George Bell, on the great plague of London, is more to be relied upon as an authoritative account. Views as to the plague in London are inaccurate. Plague had been endemic in London for many generations, and the Great Plague was only the worst of a series of epidemics of the disease which broke out at intervals. In 1550 or thereabouts, fifteen thousand persons perished of the plague in London. Ten years after that time one thousand persons were dying weekly of plague in London and so fearful was Queen Elizabeth of contagion being carried to Windsor that she caused gallows to be set up there to hang all Londoners who ventured thus far in that direction. In 1603 the year in which Elizabeth died 33,347 plague deaths were recorded in London, which it should be remembered was a city considerably smaller than in the time of Charles.

In the year of the accession of Charles I there occurred the most deadly epidemic since the Black Death. In a year's time 41,313 people died in London. At the end of the year 1664 when several cases appeared in London its population was, roughly speaking, about half a million. In the spring of 1665 the cases became more frequent and in the middle of May the authorities and the populace became seriously alarmed and the epidemic spread rapidly. In the week ending July 4th there were 1,006 cases and throughout September an average was reported of eight thousand cases. In all London not fewer than one hundred thousand persons died of plague in 1665. The mortality was almost entirely among the poor, as the vast majority of the professional and mercantile classes, in fact all who had sufficient money to get away did so. Whole families and communities perished. The Lord Mayor stuck to his post, as did Pepys, who remained as a spectator.

A few brave doctors and clergymen kept within the walls and succored the sick and dying as far as they were able. Not that the doctors could aid in staying the spread of infection as their specifics ranged from burnt amber to dried toads. The disease was frightfully deadly, a man was healthy apparently in the morning and dead at night. The red cross was put on the door of a house in which plague appeared, the door was sealed, and the sick were practically deserted. No business was done, food was scarce and all the time a burning sun blazed in a hard blue sky as if nature were mocking at the suffering and impotence of mortals.

A great deal of discussion has been held and even controversy has raged as to the nature of the plague of London. It now seems, according to Mr. Bell's book, that it was a form of the plague which flourished in the dirty and insect infested cities of Asia, and spread, as the plagues of Asia are supposed to have been, by rats. The old black rats abounded in London, living in every wooden house in the crowded filthy refuse laden streets. The dogs in London were killed, suspected of carrying infection, while the rats were allowed to go unscathed.

It may be said that the sanitary conditions of London at the time were unspeakably foul, houses were rotten and sewers open. One thing was known, it was indeed to obvious to escape notice, that the plague was virulently infectious. Drought assisted the plague; frost killed it, as it depended for its continuance on climate, rats and dirt.

The abolition of plague from England was a striking example of the effects of sanitation properly carried out. In the days of the plague London was one of the dirtiest cities of the world, and the centre of plague in England. By the strict application of wise sanitary measures it has become perhaps the healthiest. The history of the plague of London emphasizes the triumph of public sanitation, a record of which every medical man should be proud.

VITAMINES

For some years now it has been preached so persistently by certain medical authorities that the presence of vitamines in sufficient amounts meant good health and their lack or absence meant ill health or disease, that with some the subject of vitamines seemed to have become almost an obsession. Recently, a stand has been made against attributing to the vitamines such magical powers, and while allowing that their rôle is important, it has been suggested that other constituents of a diet are of equal, if not greater importance. At the meeting of the British Medical Association held last summer, John Boyd Orr read a paper before the Section on Public Medicine and Industrial Diseases, in which he endeavored to estimate the vitamines at their true value. He emphasized that those foodstuffs which were rich in inorganic constituents, liable to be deficient in the modern diet, were also rich in vitamines. He went on to say that in some of the work on these elements much of the beneficial effect ascribed to hypothetical vitamines was in reality due to the minerals present in the substances given as a source of vitamines.

In practice, therefore, the adjustment of the mineral balance was of more importance than the inclusion in the diet of substances supposed to be rich in vitamines. In short, in an ideal diet, the metabolic

balance is the goal to be strived for, and in this balance, if ill health, and goitre especially, is to be avoided, iodine in sufficient quantity must be present.

Therefore, in order to prevent goitre and other conditions owing to a scarcity of iodine, the diet should be regulated to include such food substances as contain iodine. According to Boyd the only certain sources of iodine are green vegetables and cod-liver oil, while Dr. Donald K. Tessler, of the United States Bureau of Fisheries, has been reported recently to have found that oysters, clams and lobsters are rich in iodine, containing approximately two hundred times more than beefsteak or milk. Undoubtedly then, iodine possesses quite remarkable food properties, as well as those of a therapeutic nature, and is as essential to good health as the vitamines.

By ingesting an adequate amount of food stuffs containing iodine the bodily requirements, and those of the thyroid gland in particular, so far as iodine is concerned, may be satisfied. But there are occasions when the aid of iodine as a therapeutic agent must be called in and of course, on such occasions, the physician is the best judge as to the form in which it should be given. This editorial is intended to be in the nature of a counterblast to the vitamines, or rather, to point out and bring evidence to show that there are other constituents of a diet of equal importance, not the least of which is iodine.

THE HEALTH OF WORKERS

The industrial phase of public health work is daily becoming recognized more and more as one of the most important aspects of the problem of community hygiene. In a recent issue of the *Nation's Health* are, among others, two articles of special interest on this phase of public health. The first is an account of the founding, organization and activities of the Workers' Health Bureau, by Grace M. Burnham, director of the bureau; and the second is entitled Mercantile Health Work and is written by Dr. Arthur B. Emmons, 2nd, director of the Harvard Mercantile Health Work of Boston.

The Workers' Health Bureau functions as an international office for all affiliated trade unions and is supported by them on the basis of a yearly *per capita* affiliation fee of twenty-five cents. The Workers' Health Bureau was organized a little over two years ago with three functions: 1, Analysis and research to secure exact information regarding occupational hazards; 2, the establishment and supervision of trade union health departments to provide careful periodical physical examinations for members, and special care for those suffering from occupational disease; 3, health instruction for the translation of technical data into language that workers understand, in order to teach them how to safeguard themselves against occupational and other diseases.

The painters' union was the first to adopt the program of the bureau, and may be taken as illustrative of its work. The journeymen painters and allied crafts health department was organized in New York city. This department has its own laboratory and x ray machine and is open several evenings a week and all day Saturday. The staff consists of a medical director, dentist, nurse, laboratory technician and x ray operator who is also a physician. The Workers' Health Bureau planned and organized the activities of this department and superintended the choosing of staff and equipment. Each member of the union receives a detailed physical examination, and help and advice are given to members suffering from occupational disease and in compensation cases. By uniting their buying power, members have been able to reduce greatly the cost of such an examination. "This is the application of the cooperative principle to the field of medicine, the first attempt of its kind in America," the article states. "All members of trade union health departments pay the assessment, no extra fees being charged where members require special service." Six months after the establishment of the painters' health department the workers' bureau issued a comprehensive report on conditions among painters in New York and on paint materials being used. It is publishing a bimonthly bulletin called *Health Facts for Trade Unions,* has analyzed the health hazards in forty-four trades and is organizing health programs for these. A health textbook is in course of preparation.

The Harvard Mercantile Health Work was organized nearly four years ago by a group of merchants who believed that it was good business to prevent absence and loss of time from illness or injury. They furnished the budget and the Harvard Medical School agreed to supervise the study. The first procedure was to study twenty-five subscribing stores from a sanitary and health point of view. A detailed report of each establishment was made, with recommendations for improving conditions. Among the unsanitary conditions found were improper seating; the wearing of shoes that prevented proper standing position, or were bad for the feet; bad lighting; faulty ventilation, and too high or to low temperature. Other objects studied were illness, injury and personal fitness, and the waste from these causes. It was estimated that each new person placed and trained costs from $50 to $100, and this is a total loss charged to operating expenses. It was very evident that the doctor, the dentist, the nurse, and

the physical director were all able to do their part in dealing with these people and directing them into healthier ways of living. Mental hygiene was found to be perhaps of greater importance in industrial medicine than physical hygiene. The writer states that his experience has shown that the soundest policy for financing such health work is through the organization of mutual benefit associations, each member paying small dues, and the business contributing an amount equal to the total of the dues. This method should finance a health department and also pay compensation for prolonged illness. Small concerns can band together and supply funds and pay a staff in this way.

A study of the common causes of absenteeism showed that the most expensive disease group is that of the upper respiratory infections, which showed a percentage of 39.47. Injuries to bones, joint, tendons, etc., came next, with a percentage of 8.17, a difference of great significance. The lowest cause was from eye trouble, with a percentage of 1.7.

"Public health is successful only where a strong motive is active," writes Dr. Emmons. "Fear of communicable disease is the strength behind the public health official. In mercantile medicine, the continuance of the job is the chief motive for following health advice. The mercantile health officers must be a plausible health teacher."

THE DISEASE OF THE LEARNED

Laboriously, proud science discovers facts that have long been part of the lore of common mortals, and in searching with the statistical probe into the causes of sickness among students the health director of a leading university has just found that considerable of the disability is due to the pursuit of studies for which they are not fitted. Most of us have known this since the day when we first took up the man child's burden of book and pencil and trudged unwillingly to school. From the kindergarten up there was very much that was bad for our health. Personally, English grammar (as it was taught) and Latin (in every way in which it can be presented) produced pathological effects so profound that we wonder we ever survived. Nor was there escape on the day of rest, for Sunday sickness has long been known as a disease affecting especially boys exposed to schooling in religion.

It was neither a new discovery nor a first proclamation of such a truth by men of learning, for Thomas Cogan, benevolent old Elizabethan physician, pedagogue and writer on popular hygiene (also, what is less common, popular writer on hygiene), held that "students be commonly valetudinary, that is sickly," and hence should eschew the eating of cheese, while Voltaire had much to say about the "disease of the learned."

Now that the twentieth century savant has confirmed, with statistical finality, the belief of the wise of other generations and the sad experience (rarely consulted) of children for ages past, perhaps something may at last be done about the matter, for the logical conclusion to be reached is that all school work that is disagreeable should be abolished as depressing to health and vitality. Of course we have made some seven league strides in this direction in the doling out of electives to college students, but we need more of them and the curriculum of the common school should be made so sanitary that even the first grader can take his choice of subjects. If we are to become a really healthy race this day should not be postponed.

Carrying this inference one step further, all disagreeable labor and everything done under compulsion must be bad for the health and should be done away with.

There seems to be little acquired, and less hereditary immunity to unsuitable study, and since exposure has become (no, has been made) wellnigh universal, a remedy seems the more urgent. The outlook would, however, be more alarming were it not that so large a percentage of students have found means of safeguarding their health by studying as little as possible, or better, by laboring not at all over their books. Indeed, much progress has been made (except among the few misguided, of gentle conscience who especially need succor) in avoiding the microbe of learning, for it cannot be said of the average run of college youth today that they be "commonly valetudinary." The student who spends his time on tennis or boating rather than over the duller duties of the curriculum and who fees tutors for extracting for him the meat of the disagreeables that he "must have" in order to graduate has, by such methods, wellnigh circumvented the dangers of the disease that may attack the learner.

The outlook for health in afterschool life is not so promising. True, jobs are, to some extent, elective, but, on the whole, employers have not been so thoughtful as boards of education, and few professions or occupations are without their tedious and irksome tasks. The health of many of us suffers, in consequence, either from the work itself or in the many hours that must be spent in its doing.

"We have done those things we ought not to have done and we have not done those things we ought to have done and there is no health in us" is a confession which, unfortunately, fits most of us all too well. Being interpreted in the light of both agelong empiricism and of twentieth century science, it sim-

ply means that it is still necessary for us to do things we do not like to do, and that we must leave undone because, perforce, we cannot find the time and the opportunity for them, the things we would most like to be doing. When the day is filled only with agreeable tasks not disagreeably drawn out, the collect will be forgotten.

A WORLD MEDICAL CENTRE FOR NEW YORK

New York is expected to do more than any other of the great cities in our country in many lines of action, but perhaps not all even of the medical profession know that its hospital bed capacity is actually twice the average per capita maintained by other cities. Now the contribution to the world's health is not only to be greatly increased, but New York is to have also, in the prospective Columbia-Presbyterian Medical Centre, a group of buildings where research laboratories, clinical facilities, hospital care and treatment, and a medical school will exist side by side. For we have been backward in this respect —in a systematic and organized handling of our facilities at hand—as compared for instance with Boston, with its beautiful group comprising the Harvard Medical School, and Baltimore with its Johns Hopkins University, medical school and hospital.

For the past few years the School of Medicine of Columbia University and the Joint Administrative Board of Presbyterian Hospital have been planning to build a medical centre on the site of the old American League Baseball Park, known also as the location where Billy Sunday had his famous tabernacle, which is on the corner of Broadway and 168th Street. The funds for Columbia's part in the building program have been assured, and recently the Presbyterian Hospital has launched a campaign for four million five hundred thousand dollars, which is its part of the ten million dollars to be provided.

Authorities agree that the need of such a great institution in New York City does not arise from a lack of facilities of hospital care, for of these we have sufficient and usually the best; but there does exist a lack of coordination and cooperation, which is responsible for a vast amount of waste, especially of effort and money.

The plans for the institution have been made flexible, so that if other institutions established elsewhere are willing to move and are eligible, they will be welcomed. It is planned that among the various departments there may be a psychopathic hospital, a neurological institute, a general outpatient clinic, a children's hospital, a dental school, etc., in addition to the hospital section itself, laboratories, library, and other requisites. The hospital will have ten floors for patients, each one a little hospital in itself, with equipment, staff, etc., of its own. This will make for economy of administration. Another innovation will be hotel service for relatives of patients for a limited time.

The sickness of an old and beloved negro servant of Dr. Oliver White, one of New York's most famous physicians of a generation ago, was the indirect cause of the founding of the Presbyterian Hospital. When this faithful old woman was denied entrance to a hospital because of her race, Dr. White told Mr. James Lenox that the city should have a hospital where such things could not happen. The result was that when Mr. Lenox founded the Presbyterian Hospital in 1872 he had placed at the doorway of the building, where it may still be seen, a tablet declaring the hospital to be for the use of the people of New York "without regard to race, creed, or color." These buildings have not been added to for thirty years and are declared to have outlived their usefulness, which is one of the reasons for the new Columbia-Presbyterian Medical Centre.

The site for the new institution, comprising about twenty acres, has been provided by Edward S. Harkness, a member of the Joint Board, and his mother, Mrs. Stephen B. Harkness.

NEW JOURNAL ON RADIOLOGY

The Radiological Review is a new publication to be issued bimonthly for the purpose of keeping the physician and dentist in touch with the progress of x ray and radium therapy. Harold Swanberg, B.Sc., M.D., is the editor, and the magazine will be published at Quincy, Ill. An editorial in the first issue, covering September and October, 1924, states that, so rapid has been the progress in radiology during the past decade, that it has taxed the energy of the radiologists themselves to keep up to date, and the general practitioners have for the most part not realized the possibilities of the x ray as an aid in the diagnosis of many conditions, nor of the various indications for röntgen and radium therapy. To help disseminate this new knowledge is the purpose of the *Radiological Review.*

Each issue of the review will contain a few original contributions by authorities in the fields of röntgenology and radiation therapy, and in addition many abstracts and excerpts from the important current literature on radiology appearing in the leading medical journals of the world, including seventeen different countries. A final section is devoted to reviews of books on the subject in hand.

In the first issue the original contributions are X Ray Diagnosis in Endocrine Diseases, by William Engelbach, M.S., M.D., and Alphonse McMahon, M.D., of St. Louis; and The X Ray as a Therapeutic Agent in Controlling Pertussis, by Ralph D. Leonard, of Boston.

News Items.

Personals.—Dr. J. Lewis Amster has been appointed chief surgeon of the department of gastrointestinal surgery of the New York City Cancer Institute.

Dr. Alice Hamilton, of the Harvard University Medical School, has gone to Poland and Russia, on behalf of the League of Nations, to study health conditions in industry.

Dr. William Blair Mosser, of Philadelphia, has been granted the William H. Bennett fellowship, created by gift of Dr. Charles H. Frazier, professor of surgery at the school of medicine of the University of Pennsylvania.

Dr. George Schwartz has been appointed visiting surgeon to the Heckscher Foundation Hospital, at Fifth Avenue and One Hundred and Fourth and One Hundred and Fifth Streets, New York.

Dr. Ernest Kingscote of London has recently been in New York.

Hospital Social Workers.—The American Association of Hospital Social Workers has moved its headquarters to 30 East Ontario Street, Chicago.

Venereal Disease Clinic.—The Public Health Committee of Livingston County, New York, and the County Board of Supervisors have planned to open a clinic for indigent persons of the county suffering from venereal diseases.

Insulin Fund.—An insulin fund for the treatment of diabetic patients unable to pay has been established by the Masonic Hospital Foundation at the Broad Street Hospital. Free daily clinics for instruction in the use of insulin have also been established at this hospital.

Ether Day.—The annual celebration of Ether Day was held at the Massachusetts General Hospital, October 16. The morning exercises consisted of demonstrations in the surgical amphitheatre, and at the afternoon meeting Professor Hans Zinsser, of Columbia University, spoke on the progress of medicine, with special reference to bacteriology.

New School for Psychopathic Children.—Dr. V. V. Anderson has resigned as director of the division on prevention of delinquency of the National Committee for Mental Hygiene, and has opened a school for treatment and training of children with behavior disorders and psychoneuroses. The school is to be called The Spruces, and is located at Shrewsbury, New Jersey.

Child Guidance Clinic.—The National Committee on Mental Hygiene has made arrangements for establishing a demonstration child guidance clinic in Cleveland, Ohio, as part of the Commonwealth Fund's program for the prevention of delinquency. The clinic will be under the direction of Dr. Lawson G. Lowrey, and will be held for at least one year, beginning December 1st.

Hospital Bequests.—The estate of Miss Josephine Williams, who died a few months ago in Hartford, Connecticut, has provided for $100,000 and one third of the residuary estate, or more than $400,000, for the Hartford Hospital, and an equal sum to the Massachusetts General. Several other hospitals received smaller sums, the entire amount bequeathed being more than $1,200,000.

International Clinic.—An International Clinic of Otorhinolaryngology, with instruction in English, will be held from January 15th to May 15th, and a similar clinic on Faciomaxillary surgery, from May 15th to June 30th, will be held at the St. Louis Hospital, Paris, France. The director is Dr. Fermand Lemaitre, and the secretary, Jeanne Gobreau, 120 Avenue Victor Hugo, Paris.

Commemorative Bust of Doctor Sanders.—The Alabama State Medical Society has presented to the State a bronze bust of Dr. William H. Sanders, former State health officer and professor in the medical department of the State university for many years, who died in 1918. The bust will be placed at the entrance of the State health department building at Montgomery, near the bust of the late Dr. Jerome Cochran—also a gift of the State medical association.

Mental Hygiene Lectures.—The New School for Social Research, New York, is giving a series of lectures on mental hygiene. Among them are the following: Dr. Bernard Glueck, Mental Hygiene Problems of Childhood; Dr. Douglas A. Thom, Habit Training in Children; Dr. W. I. Thomas, Psychology of Personality Development; Dr. John B. Watson, Behavior Psychology; and Dr. Frankwood E. Williams, Mental Hygiene: Its Personal and Social Assets.

International Conference on Social Work.—At the Toronto meeting of the National Conference on Social Work, held last June, a resolution was passed calling for an International Conference. This will meet at the Sorbonne, Paris, the last week in July, 1925, and excursions will be organized to social welfare agencies in London and in France. In each country a national organizing committee will recruit members, propose subjects, and choose speakers. The chairmen of these committees will constitute the International Organizing Committee.

United Hospital Fund.—The report of the United Hospital Fund of New York, for the year ending June 30, 1924, has been made public, showing that the fund had cared for 714,693 dispensary patients and 209,903 bed patients during the year. Gifts to the fund and income from endowments totalled $586,587, distributed among the fifty-seven nonmunicipal hospitals that are members of the fund, in proportion to the amount of free care given. A total of 1,470,512 days of free treatment were given, constituting forty-six per cent. of the total hospital service.

Harvey Society Lectures.—Dr. Thorvald Madsen, Director of the State Serum Institute of Denmark, will deliver the fourth Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, November 22, 1924. His subject will be "Temperature and Immunochemical Reactions."

Dr. William Einthoven, Professor of Physiology, Royal University of Leyden, Holland, will deliver the fifth Harvey Society Lecture at the New York Academy of Medicine, on Saturday evening, December 6, 1924. His subject will be "The Relationship of Mechanical and Electrical Phenomena of Muscular Contraction with Special Reference to the Cardiac Muscle."

The Post-Graduate Five o'Clock Lectures.—Public Lectures will be given at the New York Post-Graduate Medical School and Hospital as follows during the month of December on Wednesday afternoons at five o'clock:

December 3rd: Dr. Charles Gordon Heyd, "Clinical Types of Goitre—Their Diagnosis and Treatment" (illustrated by lantern slides).

December 10th: Dr. Herman O. Mosenthal, "The Treatment of Essential Hypertension."

December 17th: Dr. William H. Meyer, "Röentgen Examination of the Gastrointestinal Tract."

All practitioners of medicine are cordially invited to attend.

Society News.—The Chicago Council of Medical Women has planned meetings on the fourth Tuesday of each month, to be held at 40 East Erie Street.

The Wisconsin State Medical Association has elected the following officers: Dr. Wilson Cunningham, Platteville, president; Dr. James G. Taylor, Milwaukee, Dr. Henry A. Jegi, Galesville, and Dr. Howard E. Curl, Sheboygan, vice-presidents. A secretary will be elected in January.

The Third Annual Convention of the National Association of Police and Fire Surgeons and Medical Directors of Civil Service Commissions, met in New York, October 8th, 9th, and 10.

Harvard Appointments.—The administrative board of Harvard University Medical School has been recently announced, as follows:

President Abbott L. Lowell, Ph.D., ex-officio; Dean David L. Edsall (ex-officio), chairman; Dr. Algernon Coolidge, Dr. Harvey Cushing, Dr. Reid Hunt, Dr. John L. Bremer, Dr. Walter B. Cannon, Dr. Charles M. Campbell, Dr. Worth Hale, Dr. Simeon B. Wolbach, Dr. Hans Zinsser, Dr. Kenneth D. Blackfan, Dr. Francis W. Peabody.

The administrative board of the Harvard School of Public Health is as follows:

President Lowell, ex-officio; Dr. David L. Edsall (ex-officio), chairman; Dr. Milton J. Rosenau, Edwin B. Wilson, Ph.D., Dr. Hans Zinsser, Dr. Cecil K. Drinker.

The Cancer Commission of Harvard University comprises the following members:

Dr. Robert B. Greenough, director; Dr. Channing C. Simmons, secretary; Charles Jackson, treasurer; Dr. James H. Wright, pathologist in charge of free diagnosis; William Duane, Ph.D., research fellow in physics; Dr. Henry Lyman, research fellow in chemistry; Charles E. Barr, research fellow in biophysics; Emory Leon Chaffee, Ph.D., research fellow in biophysics; Walter S. Hughes, assistant in biophysics; Dr. William L. McNamara, assistant in pathology.

Hospital News.—Christ Hospital of Topeka, Kansas, has awarded contracts for a $500,000 building and improvements to the existing plant.

The new buildings of the Hospital for Joint Diseases, New York, will be dedicated October fifth. There will be bed facilities for 275, and accommodations for treating 1,500 patients during the day. The expenditure has been in the neighborhood of two million dollars.

A new pavilion, containing one hundred beds for private and semi-private patients of moderate means, has been opened at Vassar Hospital, Poughkeepsie, New York. The hospital is planning an appeal for $800,000 to provide a permanent annual income to carry on its work.

Dr. S. S. Goldwater, of New York, has been requested by the managers of the Memorial Hospital of Philadelphia, at Rosborough, to collaborate with the superintendent to survey the needs of the hospital, with especial reference to the erection of a maternity department.

A noteworthy amount of hospital construction is planned for in Los Angeles. The California Lutheran Hospital is soon to start work on the first unit of its $2,000,000 building; plans have been drawn for a new hospital to be known as the Isabelle J. Norris Memorial Hospital, to contain 325 general and 50 maternity beds; and the Clara Bartlett Hospital has purchased land on which to erect a $1,250,000 building.

Foreign Correspondence

LONDON LETTER

(From our own correspondent)

LONDON, *October 18, 1924.*

THE VOLUNTARY HOSPITALS

Dr. F. Kay Menzies, who succeeded that outstanding friend of the voluntary hospital system in Great Britain, as director of hospital services under the joint council of the Order of St. John and the British Red Cross Society has issued recently his report for the last year and his first report. The financial position of the provincial hospitals of Great Britain shows a striking improvement.

Sir Arthur Stanley, chairman of the joint council, contributes a foreword to the report. He suggests that the inquiry of the Voluntary Hospitals' Commission into the additional hospital accommodation required in Great Britain should be extended to cover the general need of hospital accommodation, the special categories in which it is most felt and the possibility of supplying at least part of the accommodation required by better coordination and cooperation. Dr. Kay Menzies expresses the opinion that the strength of the voluntary hospital system and the real justification for its continuance should be based upon the fact that by it is carried out an immense volume of work more efficiently and more economically than it can be done by any other known method or system. At the same time he believes that the charitable public is becoming, quite rightly, more discriminating in the selection of the voluntary institutions which it will support, and therefore any badly managed hospital, which is always more or less in debt, is no friend to the voluntary hospital system.

QUALITY OF DRUGS IN HOSPITALS

Dr. Kay Menzies critizes the large expenditure on drugs in hospitals and is of opinion that there is a considerable amount of unnecessary expenditure on drugs without any real benefit to the patient, and suggests that the question should be investigated by the honorary medical staffs "with a view particularly to determining whether there are any ingredients in each prescription which might be either omitted altogether or replaced by ingredients of equal therapeutic value but costing less."

RETIREMENT OF DR. E. W. HOPE

Dr. E. W. Hope, medical officer of health for the city of Liverpool since 1894, is one of the best public health men of the world. When Dr. Hope took office the population of the city was 540,000, in 1921 it was more than eight hundred thousand, but the total deaths in this larger population were less by nearly one quarter. During Dr. Hope's tenure of office, first as medical superintendent of the Fever Hospital and then as medical officer of health, there have been built up a system of hospitals for infectious disease, an efficient and elaborate port sanitary administration, and all the various essentials of a modern civic department.

At a meeting of the Liverpool City Council on October 1st, the Health Committee officially reported Dr. Hope's resignation and a resolution was passed recording the Council's appreciation of the excellent services at the Health Department rendered by him for forty years, during thirty of which he was medical officer of health. In proposing the resolution, Sir Archibald Salvidge described Dr. Hope as one of the most valuable public officials that Liverpool had ever possessed.

PROCREATION OF UNFIT CHILDREN

The Minister of Health was asked in the House of Commons recently, whether, in view of the continuously enlarging financial responsibilties accepted by the State with regard to unemployment, invalidity and old age, he would state the policy of the Government with respect to the procreation of children who, owing to physical or mental deficiencies, became a charge upon the State funds; and whether he was prepared to appoint a Royal Commission to investigate into the possibilities of improving the calibre of the nation by restricting the procreation of children to persons possessing a recognized minimum standard of physical and mental efficiency. Mr. Greenwood replied for the Minister and said, as at present advised the Minister does not see his way to recommending the appointment of a Royal Commission on this subject. He might perhaps add that he was not aware of the existence of any recognized standards of physical and mental efficiency.

LONDON MEDICAL EXHIBITION

The annual London Medical Exhibition, the fourteenth of the series, was held in Westminster, from October 6th to 10th. The exhibits were good and the attendance was excellent. The display of organotherapeutic products was very large as was that of electricity as a therapeutic agent. Among the exhibitors were many American firms and firms which are represented in the United States.

PARIS LETTER

(From our own correspondent)

PARIS, *October 11, 1924.*

DEATH IS BUSY

News of the medical world these days is a succession of obituary notices. The losses of medicine and surgery are great this fall. Sittings of the Academy of Medicine are being constantly suspended in token of mourning; the opening session of every professional congress is taken up with the reading of memoirs of the dead. Some had not more than local or national celebrity; others were known the world over, at least to their confrères. Of the latter, Lacassagne, Broca and Rochard passed away within the same week.

A PICTURESQUE CAREER

Alexandre Lacassagne died in his beloved Lyons—he was honorary professor at the Faculty of Medicine there—at the age of eighty-two years. The author of *Ripe Old Age* might have lived several years more had it not been for failing eyesight. Some six months ago, on leaving his home, he failed to notice a taxicab. He was knocked down, and he died from the result of his injuries. Lacassagne pre-

sented a remarkable blend of the old and the new. He began his career as *aide-major* (second lieutenant, Medical Corps) in Empress Eugénie's Own Dragoons; at the time of his death he was recognized as one of the founders of modern medicolegal science. And it was typical of the man that his will should set forth that there should be an autopsy for the general benefit of science.

DETERMINING A VOCATION

Had Lacassagne remained in France, it is probable that he would have been an Army surgeon like any other Army surgeon. But he sought transfer to Algeria for service with the *Bataillons d'Afrique,* in which are enrolled all French citizens who, on reaching military age, already have a criminal record. Most of these men are tattooed. The tattoo marks struck Lacassagne's fancy. He studied them closely, divided them into categories, and wrote thereon a monograph which attracted no inconsiderable attention. From tattoo marks, it was logical that he should take up the study of other means of identification of criminals. He published other monographs, on identification by fingernails, teeth and so forth. At about this time the Faculty of Medicine of Lyons, recently founded, was seeking young professors of talent. The Chair of Medicolegal Science was offered to Lacassagne. He accepted it, and in the course of the next thirty years, together with Coutagne and Alfred Bournet, he created invaluable archives concerning criminal anthropology. His *Treatise of Medicolegal Science,* innumerable editions of which have been published, remains a standard work.

CREATOR OF NEW SCIENCE

Lacassagne, as a matter of fact, virtually created a new science in this country. It was largely due to his initiative and to his success that the police surgeon of old, a mere figurehead in the detective stories of fifty or sixty years ago—in Gaboriau, Monsieur Lecocq, the detective, is always a much more important personage than the doctor, while at a later period Dr. Watson is the poor fool to set off the acumen of Holmes—has become the medicolegal expert of the present day, whose word carries weight and whose opinion very frequently dictates the verdict of the jury. Similarly, it is due in great part to Lacassagne's work that the Morgue in Paris has become the Institut Medicolegal and that autopsies are performed by such an authority as Dr. Paul, instead of serving, as in the past, to procure a fee for a broken down practitioner. Lacassagne figured prominently as expert in the Gouffé case, in which hypnotism was for the first time invoked as an argument for the defense—you are likely to have a similar affair in America in connection with the Hight-Sweetin case—and also in the trial of the murderer of President Carnot. Turning from practice to theory, Lacassagne attracted much attention by his refutation of the arguments of Lombroso concerning the criminal born.

THE ULTRAMODERN SCHOOL

Lacassagne was not born in Lyons. He was a regular Southerner, born at Cahors, where he and Gambetta, the great political orator of the young Third Republic, were boys together. But he loved his adopted city, where he taught for so long and where he lived for the greater part of the year. Under his influence Lyons has become a great medicolegal centre. Indeed, the disciples have outstripped the master. There is Dr. Edmond Locard, for instance, who has just published a volume entitled *Detectives in Novels and in the Laboratory.* Some consider that Locard has gone much too far in his application of the hypotheses advanced by Lacassagne. It is certainly a moot question how far a medicolegist can set up as a praphologist. Locard is so enthusiastic over his specialty that he is quite as ready to analyze the alleged handwriting of a forger as the viscera from a corpse. He has scored many successes, but he has learned also that the cobbler should stick to his last. His graphological charts are ingenious but not as infallible as a chemical reaction. The modern medicolegal expert can soon tell you whether the blood on a garment is that of a human being or of an animal; he has no sure tests for handwriting. Consequently, in this latter connection, he should be diffident. Experience has taught Locard the value of this quality. Since his consultation last year in the matter of the notorious anonymous letters concerning the Brazilian president, he has acted with more caution.

A LOVABLE PERSONALITY

Of the other noteworthy dead, Professor Broca was a lovable personality. He was a son of the great Broca, the celebrated surgeon whom Frenchmen look upon as the founder of anthropological science, and he was known more particularly as the surgeon of children. Hundreds of mothers wept at the news of his death. In the course of thirty years he had saved the lives of thousands of children. He had the tenderest of hearts, but concealed it under a brusque exterior which took aback those who did not know him. Early in his practice Broca specialized in infantile osteology, and he studied more particularly all congenital affections; he was a master in all that concerns surgery of the ear and of the brain. All who knew him admired his independent spirit, born of a mind generous and just. He hated all shams and did not hesitate to say so. Thus ever speaking his mind, conflicts were inevitable, and it was only last spring that he fought a duel with swords with Professor Cunéo, which encounter, duly chronicled in this column at the time, ended in favor of Broca.

A BORN RACONTEUR

Eugène Rochard, who was seventy-one years of age at the time of his death, was also a surgeon, but he was the very antithesis of Broca. Always suave in speech and easy of approach, he delighted in telling funny stories, many of them smacking much of the smokingroom of a sporting club. He was a born raconteur. Rochard was the son of a surgeon in the French Navy, in which service he also served for a few years. Like his father, who became president of the Academy of Medicine, Rochard was a strong hygienist, but he was always more of a teacher than a practitioner. He had been a brilliant student himself, for after resigning from the Navy he had become surgeon of the Paris hospitals thanks to remarkable success in examinations, without having been either prosector or interne, which is a most unusual achievement here.

LATIN AMERICAN LETTER

(*From our own correspondent*)

Canal Zone, *October 1, 1924.*

THE PAN AMERICAN SANITARY CODE

One of the most interesting documents which has been circulated in Latin America for a good many years is *The Handbook for the Delegates to the Seventh Pan American Sanitary Conference* which is to convene at Havana, Cuba, November 5 to 15, 1924. This is a volume of 262 pages and is written in English, Spanish and Portuguese. It was prepared and issued by the Pan American Sanitary Bureau over which Surgeon General Hugh S. Cumming, U. S. P. H. S., presides as director with Assistant Surgeon General John D. Long, U. S. P. H. S., as assistant director.

In accordance with a resolution adopted at the Sixth International Sanitary Conference held in Montevideo, Uruguay, December 12th to 20, 1920, the Seventh Pan American Sanitary Conference will make studies of the results obtained and methods employed by the twenty-one republics of the New World in the control of tuberculosis, malaria, venereal disease, leprosy, hookworm and other intestinal parasites and typhus fever. A model food and drug act will also receive consideration.

The most important matter to be taken up by the conference will be the Pan American Sanitary Code which has been prepared by the Pan American Sanitary Bureau in accordance with the instructions of the Fifth International Conference of American States.

The average reader of this letter no doubt finds this galaxy of conferences and conventions rather confusing. The Handbook contains an explanation chapter on "The Genesis of the Pan American Sanitary Code" which in addition to being a very valuable historical document reviewing the acts of the various international meetings of America, makes clear the differentiation between the two types of Pan American Meetings. The first international sanitary assemblage held in the New World was the Sanitary Conference of Washington in 1881. This was a world conference and was conceived and executed by the now defunct National Board of Health of which Dr. James L. Cabell was the president. This was followed in 1889 by the First International American Conference which had to do with many subjects including sanitary regulations on which there was a committee of seven,—which recommended the general adoption of either of the international sanitary treaties which had been entered into by Uruguay, Brazil and Argentina in 1887 and between Bolivia, Chile, Ecuador and Peru in 1888. This was the beginning of international sanitary agreements in the New World.

The Second International American Conference adopted seven resolutions looking to Pan American cooperation in the control of the major pestilences and the establishment and financing of the "international sanitary bureau with permanent headquarters in Washington, D. C." This was the beginning of the Pan American Sanitary Bureau.

The International American Conferences, of which there have been five, consider many things including postal service, customs, trade marks and similar things and sanitation. It became evident at the Second American Conference that international public health merited a conference of its own. Therefore on December 2, 1902, the First International Sanitary Conference was convened at Washington, D. C. At the Second Sanitary Conference the Sanitary Convention of 1905 was ratified. This is the sanitary treaty under which Brazil, Chile, Colombia, Costa Rica, Cuba, Ecuador, Guatemala, Honduras, Mexico, Nicaragua, Peru, Salvador, the United States and Venezuela now operate. At the Seventh Conference to be held at Havana November 5, 1924, the Pan American Sanitary Code, which is intended to modernize the Washington treaty, will come up for ratification.

This is a noteworthy document and the Pan American Sanitary Bureau is to be congratulated on the clarity and common sense which it displays. It displays a broadness of concept unimpaired by obscure verbiage. Its preamble defines its purpose as being that "of better promoting and protecting the public health and particularly to the end that effective cooperative international measures may be applied for the prevention of the international spread of the communicable infections of human beings and to facilitate international commerce and communication," and it is believed that when adopted by the conference and ratified by the senates of the several signatory nations that these things will be accomplished.

PERU REGULATES PHARMACISTS

The National Board of Health of Peru now requires the certification of all persons desiring to practise pharmacy. To secure such certificate the applicant must pass an examination before the Director of the National Board of Health and the Inspection Committee of Pharmacy. Hereafter examinations will be held each year in July and November.

WATER SUPPLY FOR CARACAS, VENEZUELA

The beautiful city of Caracas whose water supply has hitherto had an inadequate water supply of bad sanitary quality is to have a new water works system which is to cost several million bolivars. Catchment basins for the storage of rainwater, aqueducts, canals, the diversion of several rivers and the conveyance of water from El Paradero in the mountains to the capital are all included in the plan.

MENTAL HYGIENE IN ARGENTINA

The Argentinian Department of Hygiene is planning to establish a mental hygiene section which will combat alcoholism and the drug habits and assist and stimulate the proper care of all forms of mental diseases.

HYGIENIC PROGRESS IN BRAZIL

As a part of its recent regulation governing assistance and protection for abandoned and delinquent children, the Brazilian Government has organized the Council of Assistance and Protection to Minors, which is composed of the heads of organizations and institutions caring for abandoned children, officials and persons interested in education and welfare work. The council which is to oversee the care, education, lodging and the moral and physical wel-

fare of unprotected children, has adopted a comprehensive program which has the approval and assistance of practically every charitable, medical and educational force in the City of Rio de Janeiro.

The Association of Brazilian Surgeon Dentists is erecting a building which is to house its free dental clinic for poor children.

Senhor Henrique Autran, Chief of the Brazilian School Sanitation Service, has recently prepared a series of three lectures on the care of babies to be given school classes of girls over twelve years of age. Lectures will also be given to little mothers in all ports of the republic on general hygiene, tuberculosis and the means of preventing the spread of communicable infections.

The Bureau of Investigation of Venereal Disease has opened a new clinic for the free treatment of syphilis. It is well equipped and is operated by physicians competent in the treatment of syphilis. It is open every week day from 5 to 7 p. m.

CHILD WELFARE IN SALVADOR

Salvador, one of the most thickly populated republics of the New World, has recently organized a national institution to protect the child, the teacher and the school. It is known as the Salvadorean School Association, and is directed entirely by women. It will promote child welfare by providing school lunches, a school clothes fund, and medical and dispensary services, including the free administration of quinine or other prophylactic drugs to needy children, and by visiting the homes of sick, backward and abnormal children. Environmental studies will be made and faulty conditions remedied as far as is possible. Other functions will be school sanitation, the assistance of sick teachers, and the exclusion from teaching positions of the physically, mentally, and morally unfit. The Government provides a fixed income for the association, and this sum is increased by private benefactions.

BRAZIL REORGANIZES ITS SANITARY DEPARTMENT

The Pernambuco, Brazil, Department of Public Health, under Sr. Amaury Medeiros, the National Director of Public Health, has been completely reorganized, and now consists of the following sections: sanitary propaganda and education; child hygiene; visiting; nurse training and service; legal adviser's office; verification of deaths; food and milk inspections; general prophylaxis, including campaign against flies and mosquitoes; medical and surgical assistance to the indigent; bacteriological, chemical and food laboratories; preparation of variola vaccine which is sold to neighboring States; commissions for oversight of the sanitary police; antituberculosis league; and prophylaxis of venereal disease. The appropriation has increased from 50,000 milres (about $27,300) in 1894, to 1,560,176 milres (about $851,856) in 1923. The section of propaganda and education publishes many attractive posters which are widely distributed, as well as a monthly bulletin of statistics and numerous articles. The child hygiene section conducts work for prenatal and postnatal care, the inspection of wet nurses, and the examination of school children. In the fight against malaria more than thirty-nine kilometers of ditches were dug and many ponds drained in 1923.

ACADEMY OF MEDICINE PRIZES

The Academy of Medicine of Venezuela offers for competition by Venezuelans the following prizes: The Vargas Prize of 2,000 bolívars (about $386) and a gold medal, for the best treatise on tropical pathology. The José Gregario Hernández Prize, 2,000 bolívars (about $386) and a certificate of honor, for the best treatise on tropical diseases endemic in Venezuela. This treatise must be founded on personal observations and experiences of the author, and must contain a practical new contribution to prophylaxis and treatment.

The Pisquez Prize, 500 bolívars in gold (about $96.50) and a certificate of honor, for the best treatise on the treatment of tuberculosis.

SCHOOL OF MEDICINE ENTRANCE REQUIREMENTS

The Council of the Uruguay School of Medicine has decreed that an entrance examination will be required of all applicants for admission to the school after 1925. A bachelor's degree, or a certificate of successful completion of secondary and preparatory studies, will be required, and the examination will include written essays on physics, chemistry and natural history, as well as a Spanish translation from French and English or German of some scientific work on the subjects studied by the pupils in the preparatory course. Accuracy of translation and style of diction will be taken into account in judging this test.

VENEZUELAN CAMPAIGN AGAINST MALARIA AND HOOKWORM

A national decree has been issued entrusting to the National Health Board of the Rockefeller Foundation the work of planning and executing measures for the eradication of malaria and hookworm disease from the plains region, comprising parts of the States of Guárico, Anzoátegui, Monagas, Aragua, Cojedes, Apure, Carababo, Portuguesa and Zamora.

TUBERCULOSIS SANATORIUM

To care for tuberculous and pretuberculous children, the Brazilian Antituberculosis League has purchased land on Paquetá Island near Rio de Janeiro, and will erect there the Dona Amelia Sanatorium. The new institution will be exclusively a preventorium as soon as a hospital for tubercular children can be erected. During 1922, the league distributed 120,153 litres of free milk to children.

PARAGUAY'S SANITARY CAMPAIGN

The Congress of Paraguay has approved the contract signed with the International Health Board of the Rockefeller Foundation for the prosecution of a sanitary campaign. The work began January 1, 1924, and will continue for five years, 2,500 gold pesos per month being appropriated. This amount will be progressively increased.

INSTITUTE OF LEGAL MEDICINE

There was recently opened in Rio de Janeiro, the first institute of legal medicine in South America. It contains offices for physicians and a judge, an x ray room, a dark room for eye examinations and photography, a library, a morgue, a chapel and other rooms. Two nurses are in attendance.

Book Reviews

IMAGINARY PREGNANCY

Uber eingebildete Schwangerschaften. Von Dozent Dr. R. Hofstätter. Berlin und Wien: Urban & Schwarzenberg, 1924. Pp. 47.

Imaginary pregnancy may occur not only in hysterical, but also in psychically normal women. The author endeavors to show that somatic or functional changes usually lie at the bottom of this condition. Purely psychic factors may also produce symptoms as a result of functional disorders of organs, especially of the endocrine glands. There is no explanation of this occurrence. Cases are cited to show how difficult it is to differentiate between a truly imaginary and an intentionally simulated pregnancy, and various theories are offered in explanation. The author states that the English and American medical literatures contain the greatest number of cases of spurious pregnancy. In some cases it is difficult to determine the existence of a beginning or transient psychic disturbance and whether a psychosis is present or not. An unfavorable diagnosis as to the psyche must be very guarded. Almost all of the cases of imaginary pregnancy showed signs of a functional disturbance of the ovary and, indirectly, of the uterus. The subject of simulated pregnancy is also discussed. A case of imaginary and simulated ectopic pregnancy is cited. The literature on spurious pregnancy in the male is also discussed. In civilized communities it is associated with mental disorders, but the socalled couvade is practised among primitive peoples. Spurious pregnancy also occurs in animals. An extensive bibliography is appended.

INDICATIONS FOR THE INTERRUPTION OF PREGNANCY

Wann ist eine ärztliche Abtreibung rechtswidrig? F. Brupbacher. Zürich: Buchdruckerei Arnold Bopp & Co., 1924.

The question "When is medical interference with pregnancy illegal?" is a new aspect of the subject of birth control. The answer is guided by the fundamental principle of the healing art, that threatening disease must be prevented and existing disease eliminated. How does pregnancy affect women who are suffering from various diseases? Whenever the life and health of the mother is endangered and cannot be treated in any other way, the interruption of pregnancy by a physician is indicated.

Every form of tuberculosis (even the latent) and every type of cardiac disease (especially under poor economic conditions and in association with psychoses) are indications for the termination of pregnancy. In regard to renal conditions, every albuminuria of pregnancy should be considered as serious, but it is a question whether the albuminuria should be considered as a nephropathy. The nephritis of pregnancy frequently goes on to chronic nephritis, may lead to an unrecognized albuminuric retinitis or eclampsia, and may lead to fatal conditions after the pregnancy. Timely intervention is therefore necessary. The question whether otosclerosis requires intervention is still undecided. Chlorosis may lead to pernicious anemia through pregnancy. The latter is cured by interference with the pregnancy, but otherwise it is fatal. Unchangeable poor economic conditions aggravate disease and the indications for intervention are even greater.

With the poorer class of patients the intervention should take place in a hospital. After the second month the indications should be applied more strictly on account of the danger of interference. From the medicolegal viewpoint, the embryo takes human form in the second half of the second month. The medicoeugenic indications for intervention include the following conditions: atrophy of the retina, idiopathic optic nerve atrophy, glaucoma, glioma of the retina, otosclerosis, deaf mutism, muscle atrophy, dementia, psychoses, epilepsy, chronic alcoholism and especially syphilis.

INTESTINAL STASIS

Chronic Intestinal Stasis. (Arbuthnot Lane's Disease.) A Radiological Study. By Alfred Jordan, C.B.E., M.D. (Camb.), M.R.C.P. (Lond.) Oxford Medical Publications. London: Henry Frowde and Hodder and Stoughton, 1924. Pp. 230.

Jordan's thesis, based on the teaching of Sir W. A. Lane, is as follows:

In assuming the upright posture man has developed certain bands or ligaments representing "crystallization of lines of force." The purpose of these bands is presumably to aid in the support of the intestines. The first of these adventitious adhesions to develop in many cases, is a band fixing the iliac colon to the posterior abdominal wall, producing what has been named Lane's "first and last kink." This band initiates the vicious circle which culminates ultimately in the severe forms of stasis. Another band frequently met with crosses the terminal ileum, produces the classic Lane's kink in that region, and leads directly to ileac stagnation. When ileac stasis reaches a high degree, the weight of the dilated and overloaded loops pulls on the mesentery of the small intestine. This pull is transmitted upward until it exaggerates the normal duodenojejunal angle and produces a kink in this region. This in turn is followed by stasis proximal to the point of obstruction with enlargement and dilatation of the first three parts of the duodenum. It is the ineffectual attempt of this distended duodenum to empty itself that results in the socalled "writhing duodenum" that Jordan has so often mentioned in his previous contributions.

As the result of the stagnation thus brought about in the respective segments of the intestine, microbic action progresses, local catarrh develops, absorption of microbic toxins occurs into the general circulation, and the tissues of the body "depreciate" and "become vulnerable to the attacks of microbes."

The diseases that may ensue from this morbid sequence include, according to Jordan, practically all the ills that flesh is heir to, particularly ulcer and cancer.

It is obvious from the above that we are dealing with the work of an enthusiast who is not overscrupulous in offering proof to back his assertions. There is no reason to question Dr. Jordan's good intentions. Nor is there any doubt of his industry and application. His acknowledged experience, the

large number of cases here reported, as well as the three hundred odd original x ray reproductions, speak for themselves in this direction. What can be legitimately queried is the validity of the author's basic assumptions and the justice of his conclusions. Thus, it is by no means universally accepted that intestinal bands are the result of "crystallization of lines of force" due to the assumption of the erect posture. In fact the accumulating weight of evidence points heavily to the congenital nature of most peritoneal adhesions, for these are found regularly in infants and in fetuses who have never assumed the erect posture. Perhaps as careful work as any in this connection is the classic study of Samuel Clark Harvey in our own country. Nor is it generally conceded that constipation produces either colonic redundancy or adhesions. It is just as likely, if not more so, that the opposite relation is the true one. As for the claim that cancer or ulcer result from stasis, one could hardly be expected to accept this on the basis of a mere *ipse dixit*.

In conclusion we would say that although the book is undoubtedly of interest and importance to the specialist or to the advanced student of gastroenterology, it cannot be recommended without reservation to the beginner in this field nor to the general practitioner.

CANCER

Cancer—How It Is Caused and How It Can Be Prevented. By J. Ellis Barker. With an introduction by Sir W. Arbuthnot Lane. London: John Murray, 1924. Pp. xii, 416.

This book was written with the avowed object of showing that cancer is essentially a disease of civilization and preventable and statistics have been collected from all parts of the world to prove these points. While other factors of civilization such as environment, ill ventilated houses and unhealthy conditions generally are allowed to play their parts in the causation of cancer, Mr. Barker lays most stress on errors of diet, overeating and overdrinking, but chiefly on the absence from the diet of certain substances and elements in proper proportions necessary to the preservation of good health. The argument pursued is that by eating a diet deprived of such substances or elements, or by eating too much, intestinal stasis may be brought about which if prolonged may result in a poisoning of the system. This poisoning has two results in its influence on the causation of cancer. In the first place, it may supply the irritating foci in the intestines which may excite into activity the cancerous process in those predisposed. All authorities seem to be agreed that this process may be lighted up in susceptible individuals by prolonged irritation, and in the second place, long continued toxemia may so lower the defensive or protective mechanism of the body that a suitable soil is provided in which cancer may take root and flourish. Whether vitamine starvation is the principal starting point of intestinal toxemia is a moot question. The tendency recently has been to deprecate the attributing to the vitamines of the supreme importance ascribed to them by some authorities. It seems now to be the general belief that in the production of a well balanced diet the mineral salts must be present in due proportions, and if this be so the vitamines may be left to take care of themselves, because if the mineral salts are there the vitamines will accompany them. However, whatever kind of diet causes intestinal toxemia, according to Mr. Barker's views, causes cancer, and his contention is that by regulating the diet and by living in a less artificial way in all respects than at the present time, cancer may be largely prevented. The argument that a more simple and a coarser diet and a more primitive mode of living in every way will ward off many diseases perhaps, including cancer, is based on sound premises. As a matter of fact if cancer is a disease of civilization, are not all the chronic diseases more or less diseases of civilization, and ought we not to be able by leading more natural lives to stamp out in time the chronic diseases? Personal and domestic hygiene and simple diet should do much in this direction, and Mr. Barker's book supplies one more plea for such a course.

PULMONARY TUBERCULOSIS

Lungentuberkulose. Von Dr. O. Amrein. Second Edition. Berlin: Julius Springer. 1923. Pp. 141.

It is not often that one sees a German publication dealing with the vast subject of pulmonary tuberculosis which is condensed into 141 pages. It is the second edition of Amrein's book, the first having appeared in 1916. In it Amrein, who is the physician in chief of the Swiss sanatorium Altein in Arosa, describes admirably the development of pulmonary tuberculosis, the pathology, diagnosis, general and specific therapy, climatology, prognosis and the social aspect. In an appendex, Dr. Amrein's resident physician, Dr. H. Heinz, gives a description of the most important analyses which are and should be made in the laboratory attached to a well equipped sanatorium.

In the chapters on the development of the pathological process and the physical diagnosis all the modern ideas are carefully considered. The most interesting discussion is perhaps that on differential diagnosis, wherein the author speaks very lucidly of the mistakes which are apt to be made by taking the findings of dullness and râles in the regions above and below the clavicle as indications that these regions are invaded by tuberculosis. He wisely points out that such conditions may often be found after influenza and that only if these signs do not disappear after a judicious therapy of several weeks is one entitled to make a diagnosis of pulmonary tuberculosis. In bronchiectasis the typical expectoration, settling into three layers, and the general well being of the patient and absence of fever should be the deciding factors against pulmonary tuberculosis. In neoplasms and the lung, the author thinks that when percussion and auscultation reveal large areas of dullness, it is an important diagnostic sign, even if microorganisms which strongly resemble the tubercle bacilli are found. Amrein here recalls the interesting work of Maher, of New Haven, who, at the Washington Congress in 1908, described acid fast nontuberculous bacilli found in cases of malignant tumors of the lung. As other diseases which must be differentiated from pulmonary tuberculosis there are enumerated echinococcus abscesses and the various pneumoconioses and actinomycosis. The author thinks that in typical bronchial asthma the course of the disease and its afebril state should be the de-

ciding factor. He strongly advises against tuberculin injections to determine pulmonary tuberculosis, saying that a positive reaction may only indicate that there is a localized tuberculous lesion somewhere in the body, while if pulmonary tuberculosis does exist the conditions may become aggravated.

Under general therapy, the author protests against long journeys to distant sanatoria or climatic regions. Among the many good medicinal prescriptions given by the author we would wish to mention the one he recommends against small hemoptysis. It is a combination of calcium chlorate, calcium lactic and calcium citrate, of which he gives one half to one gram every two or three hours.

Amrein emphasizes the importance of rest in all stages of the disease, particularly when there is an active process; but he also acknowledges that many patients cannot be persuaded to take the prolonged rest cure (*ewiges Liegen*) and one must resort to psychotherapy and to various means to occupy their minds and convince them of the value of rest. The author comments favorably on Knopf's new method of reducing the respirations in number and limiting them to the diaphragm; he thinks this of value in cases where the patients have learned to control their cough. In the description of the *modus operandi* and the physiological results of this method, an evident but unfortunate typographical mistake occurred. It is stated that by reducing the respiration from twenty to ten a minute, 30,000 excursions of the lung were saved in five hours. It should, of course, read 3,000.

Nostalgia in the tuberculous patient is considered a condition which the physician in charge must endeavor to combat by his own personality; an encouraging, comforting and sympathetic attitude will help materially. The author, of course, realizes the inestimable value of artificial pneumothorax as a means to control severe hemorrhages and in such cases as do not do well under ordinary methods of treatment. As contraindications considerable bilateral involvement, noncompensated cardiac trouble, nephritis of both kidneys, and advanced laryngeal tuberculosis are mentioned. A short description of thoracoplasty and section of the phrenic nerve is given and these are recommended when artificial pneumothorax cannot be performed. In the chapter on prognosis nothing new is offered, but Dr. Amrein's warning concerning the difficulty of foretelling the outcome of pulmonary tuberculosis will bear repeating and may well be taken to heart by all who are called upon to make a definite prognosis. "Sometimes seemingly favorable and light cases progress rapidly and end fatally, while cases considered as hopeless improve and are economically cured, though clinically their lesions persist."

The concluding chapters treat of the hygienic education of the masses and a thorough campaign for timely diagnosis and treatment. The author's appeal for a new international union of tuberculosis workers is pathetic, and he deeply regrets that *L'Union internationale contre la Tuberculose,* inaugurated by England and France in 1919, have excluded their one time enemy Germany. As a citizen of little neutral Switzerland, which during the war welcomed the tuberculous soldiers of all the warring countries without distinction and helped in their reestablishment to health, he pleads for a new union of all the civilized nations to combat the common enemy tuberculosis.

The book can be recommended to the specialist as well as to the practitioner as a concise exposition of all that is known today of the subject of pulmonary tuberculosis.

DIABETES

The Pathology and Treatment of Diabetes Mellitus. By George Graham, M.A., M.D., F.R.C.P., First Assistant in the Medical Clinic, St. Bartholomew's Hospital. Oxford Medical Publications. London: Henry Frowde and Hodder Stoughton, 1923. Pp. x, 179.

New Views on Diabetes Mellitus. By P. J. Cammidge, M.D. (Lond.) and H. A. H. Howard, B.Sc. (Lond.). Oxford Medical Publications. London: Henry Frowde and Hodder Stoughton, 1923. Pp. xiv, 611.

The basis of Graham's book is the Goulstonian Lectures on Glycemia and Glycosuria (1921), which have been revised and amplified. Part I deals with the physiology of sugar metabolism; Part II describes the different types of diabetes, the methods of their differentiation and their treatment.

It is maintained that it is unwise to give any (except vegetable) carbohydrate diet until the fasting value of the blood sugar is brought below 0.12 per cent. for a considerable time. Rigorous dietetic restrictions or large doses of insulin may be necessary to do this. The advantage of the author's method is that only one dose of insulin a day is required and also a much smaller dose. Insulin exhibits the best results in diabetic coma. The causation and treatment of diabetic coma is discussed in detail.

The most practical part of the book is found in the Appendix, which includes the ladder diet used in the medical clinic of St. Bartholomew's Hospital, recipes for the Allen agaragar bran biscuits and agaragar jellies, tables of food values, tables showing the metabolism and growth from birth to puberty, methods of estimating the amount of sugar in urine and blood, tests for diacetic acid and acetone, pentose, levulose and homogentisic acid and the carbon dioxide in the alveolar air. The aketogenic ratio is also discussed. Diagrams which indicate the normal standard of calories to the square metre of body surface an hour and the total calories a day, as well as the basal maintenance diet and maximum calorie diet (insulin), are also given.

* * *

Cammidge devoted over twenty years to an attempt to throw fresh light on errors of carbohydrate metabolism. He found that pancreatic dysfunction alone did not explain all the phenomena observed in diabetes. Howard was in charge of the chemical work. Through the development of modern methods of analysis and processes of investigation a closer approach has been made toward the ultimate solution of the problem of the causes of diabetes. With them the authors have been enabled to advance a scientific basis for the glycosurias and to account for the varying clinical symptoms, prognosis and the effects of different forms of treatment observed in different cases. New methods of handling particular varieties of glycosuria and hyperglycemia were also suggested.

These have been found to pave the way for further developments. Typical cases to exemplify each variety of case or point of treatment are cited.

Normal carbohydrate metabolism appears to depend mainly upon the following factors: 1, the power of the liver and other tissues to lay down glycogen; 2, the balance between the fixed acids and bases of the systemic circulation; 3, the influence of sodium chloride and other salts upon glycogenolysis; 4, the existence of a possible antiferment in the pancreas, which acts upon glycogen; 5, the influence of endocrine glands on glycogenolysis, and 6, the control of the nervous system upon hydrolysis of glycogen into sugar. The plasma is the vehicle by which the transportation of sugar is chiefly carried out in diabetes.

The main disturbances of carbohydrate metabolism depend upon the following factors: the acid base equilibrium, inorganic salts, the hydrochloric acid in the stomach, the pancreas, the liver alone and in combination with other tissues, renal permeability, the ductless glands and the nervous system. This is summarized in a very useful table. The chapter on diagnosis and classification shows the methods of applying the different tests to determine the effective factor or factors involved. The chapter on the principles of treatment deals with the physiological effects of fasting, carbohydrate "cures," vegetable diets, milk diet and casein preparations, drugs, organotherapy and the dietetic treatment. In the chapter on treatment (special application and prognosis) the distinctive features of the various types of true diabetes and glycosuria and the complications are discussed in detail.

The bibliography is very extensive and the entire work is profusely illustrated by charts and diagrams, making this a valuable book to those who wish to keep strictly up to date on the subject of diabetes and its treatment. The point of view is entirely different from that presented in the usual book on the subject.

BONES AND JOINTS

Normal Bones and Joints. Röntgenologically Considered. Two Hundred and Twenty Röntgen Ray Studies on Sixty-one Full Page Plates and Thirty-four Text Illustrations. Annals of Röntgenology, Volume Four. By Isidore Cohn, M.D., F.A.C.S., with a foreword by Rudolph Matas, M.D. New York: Paul B. Hoeber, Inc., 1924. Pp. 218.

This is volume IV of the *Annals of Röntgenology,* edited by James T. Case, M.D. It is printed throughout on heavy calendered paper and is a perfect example of book making.

One subject very exhaustively covered is the normal radiographic anatomy of the elbow, from birth to adult life, with the errors in the interpretation of röntgenograms due to ununited epiphyses and the like. A sufficient number of radiograms of actual fractures and dislocations are given in addition to normal examples which in some cases had been misinterpreted. The shoulder, wrist, hip, knee and ankle joints are treated in the same useful manner though more briefly.

A large and very important part of the volume fully describes the various centres of ossification in the above mentioned regions when they first occur, when they are complete and, in the case of epiphyses, when they unite. The author presents not only his own observations fully illustrated by radiographs but also records the observations of Gray and other anatomists and also of Rotch and other clinicians. If is stated in the preface that this information is of great value not only to surgeons but also to pediatrists and endocrinologists.

To the reviewer it seems that the greatest use that can be made of this section of the book is in determining what we may call the osteological age of children or young persons. The late Dr. Rotch proved conclusively that this was a reliable measure of mental age which in cases of retarded development is very much less than the actual age in years or what would be indicated by size and appearance. Thus the reviewer knows a young man of twenty with the mind of a perfectly normal boy of twelve and also the ossification development of a child of twelve. The reviewer does not regard these facts as cause and effect but both as arising from a common cause. The röntgenologist would report the developmental age and recommend that the patient should not be forced in school or factory beyond this retarded development. The present book is the best aid to the röntgenologist in such a study that has come to our notice.

MALIGNANT GROWTHS

Allgemeine Pathologie der malignen Geschwülste. Von Dr. Max Borst, Professor der allgemeinen Pathologie und der pathologischen Anatomie der Universität München. Mit 21 Abbildungen und 6 Tafeln. Leipzig: Verlag von S. Hitzel, 1924. Pp. iv, 322.

The pathology of malignant neoplasms is studied from the viewpoint of the most recent experimental evidence. This book is based upon the author's contribution to Zweifel-Payr's *Handbook on Malignant Tumors,* which has been elaborated by additions to the text and additional illustrations, an extensive bibliography, a table indicating the classification of tumors according to histogenetic principles and, principally, by the addition of the chapter on etiology. The index and the very extensive bibliography at the end of the book are very valuable. Only the most recent literature is cited.

Tumor formation is considered as the resultant of cellular degeneration, on the one hand, and of the surroundings of the cells and the entire body on the other hand. Both of these etiological complexes may contain hereditary and congenital, as well as acquired factors. Constitutional factors and predisposition must also be considered. Therefore they may be general, local (organic and systemic) and cellular in origin. The chapter on general morphology considers the various tissue elements and the total organization of malignant tumors. The chapter on general biology includes the functional activities of tumor cells, the malignancy, the growth and local methods of dissemination, the formation of metastases, recurrences, the general reactions (cachexia, etc.) and spontaneous recovery. The histogenesis of malignancies is considered.

Blastomas are divided into two main groups—those of connective tissue and those of epithelial origin. A third group consists of mixed tumors. All three groups show homotypes (mature) and heterotypes (immature). Irritation is only a contributory cause of malignancies. The parasitic and endogenic theories are discredited. General bodily conditions, the constitution and systems of organs, tissues and, finally, the constitutional predisposition of cells must be blamed for the causation of cancer. The chapter on experimental tumor formation is very

comprehensive. The various types of sarcoma, carcinoma and special forms of malignancies and malignant mixed tumors are discussed in detail. The table of classification of tumors according to the tissue of origin is very helpful.

PREHISTORIC MAN

The Giant Cat. Or the Quest of Aoun and Zouhr. By J. H. Rosny. Translated from the French by the Honorable Lady Whitehead. New York: Robert M. McBride and Company, 1924. Pp. 242.

It is fitting that a French writer should unfold this tale of prehistoric man. The most famous culture sites known today are in France, and recent investigations have brought them to the fore in current interest. An attempt to recreate the life of man on the brink of modern thought, together with the correlation of much scientific data, has resulted in a successful whole. Especially is the prodigality of tropical nature stressed, in that experimental stage of evolution where the preying of the carnivores on animal life counted for very little since life was so fruitful. The teeming forests and lowlands, the rank beauty of the landscape, are suggested, and yet not over stressed, with a subtle understanding of primitive man's more utilitarian view of life.

Two men, one of a mighty race, the other, the weakly survivor of the "men without shoulders" of higher mental but lower physical rank, make the grand tour, so to speak, of Chellean Europe, we take it. They venture where their kin have never been. They reach hunting fastnesses to which man in his rise has driven types of beasts that as types are slowly dying out. They find the sabre tooth mammoths larger than any their sages could sing of, the giant cat of the rocks, a spectre that must have ruled dreams for generations. They also find man, of varying grades of development,—and the battle between humans is no more ruthless than between man and beast, and beast and prey. But the reason for man's ultimate victory is seen in the gradual disentangling of thought. The weakling must think to survive. He devises ways and means of livelihood, he remembers, and he senses into the future. Although his stock will die out, he has increased the sum total of primitive knowledge. The next thinker who is forced to live by his wits will have a broader base to build upon. The next age of man will have a wider horizon.

To get the *feel* of prehistoric days, read this book. It may not be altogether successful, it lacks the grip of Jack London's *Before Adam,* but it will serve excellently to give the reader who spends little thought on whence we came some concept of the intricate, marvellous process of evolution.

HUMOR

Munchausen, M.D. By Julian Walter Brandeis, M.D. New York: The Quip Publishing Co., 1924.

In this interesting little volume, the author, a well known physician, takes his own 'round the world flight—of fancy. Dr. Munchausen makes an affidavit swearing to the truth of the narrative, and is supported by the signed statements of such famous truth tellers as Gulliver and Sinbad. Being just out of colloge and already earning an income of vast proportions from his practice, Munchausen decides that he needs a vacation and takes a tour which leads him into all sorts of unexpected places and makes him a participant in or witness of the most marvellous experiences that a medical man possibly can encounter. Whether he jumps head first into love with the Flowerjah of Blootch, or into the waiting jaws of a hungry man eating shark *á la Jonah,* he always manages to come out of his scrapes unscathed and ready for the next experience.

All the medical man's favorite poses are dragged out so we can see them in their humorous light, and the *isms* and *ists* come in for their share of the fun.

The reviewer got a good many hearty laughs out of this little volume and can commend it as a splendid tonic after a hard day's grind. There is a vast amount of real good fun between the covers of this little book, which any medical man with a normal liver will enjoy.

Medicoliterary Notes.

The work of the American Relief Administration in Russia is praised in the highest terms by Sir Philip Gibbs who contributes an article on the subject to a recent number of the *World's Children* (London). Among other forms of relief work done was the sending of 1,742,401 individual food packages, each one containing a normal ration for three persons for one month. Needless to say, this was often made to last much longer. It is estimated that these individual food remittances, apart from the mass feeding in the famine areas, were equivalent to rations for twelve million people for a month. The mass relief supplies went to starving rural districts and to children, while the special food packages were sent to students, teachers, artists, scientists, etc., whose poverty was perhaps hidden from the public eye but none the less tragic.

* * *

The *Atlantic Monthly* for October contains an entertaining and clever article from the pen of Simeon Strunsky, who takes Lamarck's doctrine on the transmission of hereditary characteristics and applies it to the workings of governments. The title is *Notes from a Front Page Laboratory.*

* * *

The U. S. Bureau of Public Roads has recently made a study of milk transportation for several of our large cities. This survey, a report of which appears in a late issue of *Public Roads,* reveals that the motor truck has largely replaced all other methods of delivering milk to cities.

* * *

When we resort to strong language over mistakes or omissions in the New York telephone directory, we are prone to forget that the printing of these volumes is probably the biggest printing job in the United States as well as the most highly specialized; that, according to a recent report of the Bell system, about fifty thousand changes in the name list are made each year; and that it takes thirty thousand tons of paper annually to make the books.

* * *

Books, the *Herald Tribune's* new literary review, reprints a letter from the *London Times Literary Supplement* giving Sir William Osler's medical opinion on the nature of the poet Byron's last illness and the cause of his death, which has always been the subject of much discussion. The letter states that in 1910 Osler read the accounts and documents, including Dr. Bruno's report of the postmortem examination, relating to the poet's last illness and death, and made the definite statement that he felt quite sure that Byron's illness must have been meningitis, and that therefore the doctors could not have possibly saved his life by any means whatever. Since, as is well known, Osler was unusually familiar with postmortem pathological conditions as well as with symptoms during life, his opinion should

have great weight and should be publicly recorded. In Harold Nicolson's recent book, *Byron: The Last Journey*, it is suggested that typhoid fever or pernicious malaria might have caused death.

* * *

One of the books of the month, published in London by Hutchinson & Company, is the life of Eleonora Dusé by Jeanne Bordeux. It is called *Dusé of the Beautiful Hands* and is said to contain a number of incidents in the life of the great actress heretofore unknown to the public.

* * *

A recent number of *Kosmos* (Stuttgart) contains an interesting article by Hans Welten entitled "Hunger: A Biological Study."

* * *

Dr. Little's Dog Book is one of McBride's late publications. The author is George W. Little, D.V.M., who for many years was head physician of the American Society for the Prevention of Cruelty to Animals. The book is designed for the layman as well as for the breeder of pedigreed dogs, and gives valuable information on the care of dogs in health and sickness.

* * *

O. Henry's birthplace, Greensboro, N. C., has erected a stone tablet to mark the site of the house where he was born. The stone was unveiled by the granddaughter of the uncle in whose drug store O. Henry worked.

* * *

When a workingman of Pressburg recently felt that one of his back teeth had ached too long, he went to a dentist for help. What was the dentist's surprise when he hauled out, not a tooth, but a bullet. Then the victim remembered that while in the Austrian army during World War he had been hit in the jaw by a spent Russian bullet, which he thought had dropped out after inflicting a slight flesh wound.—*New York Times.*

* * *

Louise Pound contributes an amusing and clever article to a recent issue of the *American Mercury* called Notes on the Vernacular. She discusses and explains why both the omission and inclusion of the letter R make for humor, and dissertates upon the sources and effects of various forms of abridged writing, of indefinite names, and other language forms pecular to American dialect.

* * *

The London correspondent for the *Irish Times* (Dublin) comments as follows upon *Fata Morgana*, successfully produced last season in New York by the Theatre Guild: "*Fata Morgana*, at the Ambassador's Theatre, is a feeble and inelegant effort to show the awakening of love and the inevitable disillusionment. The author has made the subject of the experiment, not a sweet young girl of eighteen, but a youth of the same age. If tears were a sign of intense drama, then this would be a good play, for everybody is either in tears, or on the verge of them, at least once in the evening, and the curtain comes down on Tom Douglas, the young film star, crying bitterly for his first love. . . ."

* * *

The same paper reports a marked and continued success for Sean O'Casey's clever play, *Juno and the Paycock*, now running in Dublin, and, rumor has it, to be brought to New York in the not far future.

* * *

Karel Capek, the brilliant young Czech author, comes of a medical family. He speaks several languages, and is conversant with ethnology, folklore, psychology, geography, physics, and chemistry. His one slight ambition at present is to write one hundred books before he dies, and to absorb all human knowledge. "The man who knows all must die," he writes, "but I hope not to die till I know all."

* * *

The *Living Age* has converted its first issue of each month into a much fuller monthly edition in order to include the vast amount of material too full or detailed for brief weekly comment. The monthly edition for October 4th contains full excerpts from *The Guardsman*, the play of Franz Molnar, author of *Liliom* and *The Swan*. *The Guardsman* is now running in New York under the direction of the Theatre Guild. The same number of the *Living Age* contains the translation of an article by A. Rogozhin in *Dni*, the Russian daily paper published in Berlin, entitled *The Islands of the Dead*, and giving a full review of Albert Londres' book, *Au Bagne*, which described so vividly the horrible conditions at Guiana, the French government's prison, that it has been abolished.

* * *

The September issue of the *North American Review* contains an article by Winifred Kirkland on *The Doctor on the Stage*, that usually much maligned victim of the dramatist's pen. By the way, one who is not thus treated is the young military surgeon in *What Price Glory?*

* * *

Who's Who in America, 1924-1925, published by Marquis in Chicago, is just out. It has now attained the scope of more than 3,700 pages of biographical material.

* * *

The Children's Foundation of Valparaiso, Indiana, has recently issued a survey and review of present day knowledge on education and child welfare under the title of *The Child: His Nature and His Needs*, edited by Prof. M. V. O'Shea, of the University of Wisconsin. The contributions are by authorities on the various phases of the subjects treated in the book.

* * *

The *Yale Review* for October contains an unusual number of interesting articles, among them The Future of Great Britain, by Prof. Raymond Turner; The Education of Industry, by L. P. Jacks; Charity in the Work of May Sinclair, by Jean de Bosschere; Rasselas in the New World, by Chauncey Brewster Tinker; and Mr. Galsworthy as Artist and Reformer, by Dorothy Martin. There is also a letter from Henry James to an old friend written in 1915 and explaining why he was impelled to renounce his American citizenship.

* * *

Arthur Symons, the well known essayist and critic of art and literature, has in the *Golden Galleon* for October a most enlightening article on Duse and D'Annunzio. He throws many interesting sidelights on the art and characters of both, including Duse's own comment on D'Annunzio as an artist. He quotes her as having said to him: "You ask me what I think of d'Annunzio. He is a great poet, a great lyric poet, but not in the real sense a dramatist." "In these words," add Symons, "she confessed the most vital fault in the man whose fame she had made." Another interesting contribution on d'Annunzio is in the June issue of the *Dublin Magazine*—A Visit to D'Annunzio, by J.M.H.

* * *

Julian S. Huxley, writing in a recent number of the *Manchester Guardian*, describes the German zoologist, Spemann's, recent discovery of the cause of differentiation as shown in the fertilized egg of the newt and other amphibia. After the first stage in which the egg seems to consist only of raw materials for the constructive processes, "the next step is the division of the egg into two, four, eight, and so on till several dozen or (in the newt) several hundred small cells have been produced from the original large one. Then, in the newt and other amphibia, a new process occurs. At one place near the equator of the egg, the smaller, less yolk laden cells begin to multiply more rapidly and to grow down as a fold or flap over the large yolky cells. The infection, so to speak, spreads sideways; so that, as the fold extends downward, it enlarges laterally, its free edge becoming at first crescentic, then semicircular, then horseshoe shaped, and finally circular. The circle diminishes until at last the whole of the yolky part has been overgrown. The edge of the fold is called the lip of the blastopore. Directly after this the first signs of differentiation become apparent. The side on which the fold first appeared becomes the back, for here appears a thickening which soon becomes converted into the rudiment of the brain and spinal cord. Below this the notochord, forerunner of the backbone, is formed, and on either side the rudiments of the muscles. The cavity of the digestive tube appears below the notochord, and the kidneys on either side. In a very short time the rudiments of all the chief organs of the future tadpole are blocked out; differentiation has started, and, once started, continues to its appointed end."

Abstracts from Current Literature

GYNECOLOGY AND OBSTETRICS

Dysmenorrhea. — According to H. Meyer-Rüegg (*Schweizerische medizinische Wochenschrift,* April 3, 1924) dysmenorrhea should not be considered as a symptom, but rather as a sharply defined disease picture, with the exclusion of all pains produced by inflammatory or other organic affections of the genitals—a purely functional disturbance (uterine spasm) produced by a combination of psychic and menstrual processes. It is for this reason that dysmenorrhea is relieved by psychic treatment and the use of antineuralgic remedies. The author advises against local treatment, which, in addition to the ethical injury, also give uncertain results.

Local Anesthesia in Minor Gynecological Operations. —Stephan Polgár (*Zentralblatt für Gynäkologie,* April 5, 1924) states that owing to the complicated nerve supply of the female genital organs conduction anesthesia of the pudendal nerve is not sufficient for the purpose of absolute painlessness and that in addition the inferior hemorrhoidal, the posterior labial, perineal, the posterior cutaneous femoral, the anococcygeal and the dorsal nerve of the clitoris must also be anesthetized. Conduction anesthesia of the pudendal nerve (perineural injection) is obtained with the following technic: The tuberosity of the ischium is fixed with one finger and the spine of the ischium with the other through the vagina, and the needle is controlled in its passage either through the vaginal wall or the perineum toward the tuberosity. If the perineum is torn circular injections are made around the rectum.

Paradoxic Ischuria in the Puerperium.—W. J. Zempléni (*Zentralblatt für Gynäkologie,* March 29, 1924) considers paradoxic ischuria in the puerperium to be the result of a paralytic disturbance of innervation from trauma. It is frequently observed, especially in head presentations, that the slowly passing head in the pelvis compromises the urethra when the bladder is overfilled. If there is no atony or paralysis, the mother complains of great pains and a marked strangury. Total or partial incontinence (without retention) is also often observed in the puerperium. The complication of retention with incontinence constitutes paradoxic ischuria.

Eclampsia and the Justification for Active Treatment. —The investigations of Walter Fürst (*Zentralblatt für Gynäkologie,* April 19, 1924) confirm the old belief that the early treatment of eclampsia is far better than late treatment. The most effective early treatment consists in rapid delivery, which eliminates the etiological factor of the eclampsia, pregnancy, and also the injurious effects of the labor. The only reliable method of rapid delivery is section, provided the soft parts are sufficiently dilated. All of the dangers that are usually attributed to rapid delivery or the active method of treatment do not apply in the case of transperitoneal cervical section. The outlook for the preservation of fetal life is best with abdominal Cæsarean section. All cases of eclampsia should be given clinical treatment. Only when such is impossible should an expectant plan of treatment be instituted.

The Relation of Endometrium to Ovarian Function.— C. C. Norris and M. Vogt (*Surgery, Gynecology and Obstetrics,* January, 1924) believing that the endometrium possesses a definite endocrinal function, and that this function operates in conjunction with the secretory function of the ovary, and is probably subservient to it, present the following conclusions:

1. The theory that the endometrium possesses an endocrinal function is at present based only upon physiological and clinical proof. The fact that the endometrium differs histologically from other endocrinal glands is no argument against the theory, since all other endocrinal glands differ one from the other, in this respect.

2. The endometrium probably possesses a definite endocrinal function, which, like other endocrinal glands, acts in conjunction with certain socalled ductless glands, particularly the ovary, to which it is most likely subservient.

3. The endocrinal function of the endometrium probably fluctuates with the menstrual cycle, being most active during the premenstrual period.

4. The chief clinical evidence on which this theory is based lies in the established fact that the proportion of women who suffer from nervous phenomena after a hysterectomy with conservation of one or both ovaries is much greater than that of those who exhibit painful or palpable changes in the conserved ovary.

5. The most conclusive evidence is found in those patients who have been treated with radium for the arrest of benign hemorrhages. It is difficult to conceive that in almost every case so treated both ovaries are rendered functionless. Furthermore, there is much experimental evidence that tends to show that in these cases the action of radium is limited to the uterus.

6. In operations upon the uterus, ovarian conservation is of distinct value, even if panhysterectomy is performed; the ovaries function better, however, and have a longer functional life, if part of the endometrium is preserved.

7. The thickened and permanent premenstrual stage of the endometrium, so frequently present in patients suffering from uterine myomata, is the result of stimulation of the endometrium by the presence of the tumor, and accounts for the prolonged bleeding that is often present.

Chronic Leucorrhea.—A. H. Curtis (*Surgery, Gynecology and Obstetrics,* Nov. 1923) says that the sources of chronic purulent leucorrhea can usually be definitely localized. These foci of infection are important factors in the production of systemic disturbances, as well as local distress. Cervical discharges may persist after the disappearance of infection; this is notably true if extensive hyperplasia of the cervical glands has occurred. Relief from these innocent discharges is not essential, provided they cause no mechanical annoyance. Available measures in the control of chronic leucorrhea consist in eradication of gland infection in the vicinity of the urethra, dilatation of cervical strictures, and destruction of hyperplastic glandular tissues of the cervix. Whether the latter is to be accomplished by endocervix removal or through the use of radium should depend upon the character of the pathology encountered, modified by the experience of the surgeon in charge. Destruction of infected Skene's ducts and urethral glands, together with thorough dilatation and radium treatment of the cervix, has been followed by recovery from chronic leucorrhea in eighty-seven per cent of one hundred and four patients.

Cardiopaths in Pregnancy and Labor.—W. C. Danforth (*Surgery, Gynecology and Obstetrics,* December, 1923) reports on a number of cases of decompensated hearts with the following conclusions. The functional capacity of the pregnant woman's heart should be considered as early in pregnancy as possible. The aid of the internist in this and other things is of the greatest value. Immediate attention must be given to any evidence of overstrain of the heart. Of the lesions commonly seen, mitral stenosis and myocarditis are by far the most to be dreaded. Delivery by the natural passages is ordinarily preferable, aided by morphine in the first stage and operative delivery if needed in the second stage. Cæsarean section is, as a rule, not the best treatment for women with decompensated hearts.

Afterresults of the Abdominal Operation for Retroversion.—Alice Bloomfield (*Lancet,* February 2, 1924) states that cases of retroversion complicating prolapse should be treated as cases of prolapse. Abdominal operation alone rarely, if ever, cures these cases, and their inclusion in statistics of operations for retroversion leads to confusion. Retroversion is not a disease in itself and never, with the possible exception of the Bonney syndrome, gives rise to a definite train of symptoms. It is usually complicated by other pathological findings, and it is these, as a rule, which indicate operative treatment, and upon which the relief of symptoms largely depends. If no complication is found on clinical examination, and sterility is complained of, operation is sometimes indicated, as closed tubes may be present and a better chance of conception seems to be given after dilatation of the cervix, if the uterus is replaced and retained in the anteverted position. In many cases an undoubted nervous element is present, the significance of which must be carefully assessed before operative treatment is undertaken, and in considering the result of such treatment. Pregnancy does not seem to exert any deleterious effect on the clinical results of treatment beyond the fact that it makes prolapsus more common.

Baden Statistics on Eclampsia in 1921 in the Light of a Functional Therapy.—W. Gessner (*Zentralblatt für Gynäkologie,* February 16, 1924) reports that the active eclampsia therapy gives the most rapid and complete restoration of disturbed function, as is shown plainly by the frequently existing complete anuria, because it leads immediately to the relief of tension of the abdominal wall and through it to a normal renal circulation and function. It is better and relatively less dangerous than any other procedure and it is a true functional therapy. In the treatment of puerperal eclampsias, the Veit procedure with venesection is usually sufficient in those favorable cases, in which the eclampsia appears in the first few hours after delivery. However, it is not sufficient in the far more serious cases of late puerperal eclampsia. Nevertheless, the late cases of puerperal eclampsia will show the same mortality as the early cases of eclampsia of pregnancy (up to the seventh month). In these cases only a timely operative interference will be of value. The important element is not the operative interference but the timely interference. Podalic version or perforation is preferable to the loss of both the mother and the child.

The Starvation Toxicosis of Pregnancy.—Erich Opitz (*Zentralblatt für Gynäkologie,* January 12, 1924) believes that the sudden requisition for material needed for the development of the fetus in the uterus deprives the maternal tissues of these substances, resulting in deficiency manifestations, such as hunger edema, scurvy, beriberi and similar conditions. He does not believe in the formation of a special kind of toxin and he calls attention to the striking fact that pregnancy, carcinoma and severe chronic infectious diseases have in common a series of modern reactions, such as cobra poison hemolysis, sedimentation rapidity of red blood cells, Abderhalden reaction, stalagmometry, high antitrypsin titre, and complement fixation, in which process the growing ovum particularly and a growing neoplasm are considered as factors which deprive the organism of certain factors. The author supports his theory by the similarity between the manifestations of the toxicosis of pregnancy and those of known deficiency diseases, especially the starvation edema of war and the deficiency diseases in infants from not getting sufficient fat. He also shows that from the beginning of pregnancy the centre in the floor of the third ventricle, which seems to control the metabolism of water, sugar and sodium chloride is influenced by the pregnancy, and its function is diverted by way of the vegetative nervous system as a result of the influence of the implanted ovum.

Chemical Hysterectomy. — W. Wayne Babcock (*American Journal of Obstetrics and Gynecology,* June 1924) describes packing with zinc chloride tape as a rapid and easy way of obtaining the effect of a hysterectomy in certain selected nonmalignant conditions. The endometrium of the cervix, corpus and cornu, with a thick layer of the surrounding metrium, is quickly sterilized and devitalized. and is expelled after some days as a sphacelus, leaving a fibrous uterine mass without cavity or discharge, resembling an infantile uterus. The zinc chloride gauze tape used is about one centimetre wide, placed in saturated zinc chloride solution and blotted up before use with sterile dry gauze sponges to avoid excess of solution dropping from the tape. Local, nitrous oxide or narcotic anesthesia is used during the operation. The cervix and internal os are dilated sufficiently for the introduction of a uterine packer, the uterine cavity explored, and a packer, preferably with an obturator, introduced well through the internal os. The cervix and uterine cavity are thoroughly packed, with the vagina meanwhile protected by a strip of gauze impregnated with dry sodium bicarbonate. Finally, the vagina is so packed with other strips of the soda gauze that the cervix and the caustic tape issuing from the cervix are completely surrounded. The packing is withdrawn in seventy-two hours if fifteen mils or less of gauze are used, in eighteen hours after thirty mils of gauze, and in four and a half hours after sixty mils. With uterine walls only three millimetres thick, the caustic should be left in over six hours; with walls six millimetres thick, not over twelve hours, and with walls one centimetre thick, not over twenty hours. The patient should usually be kept in bed for a week, and under supervision for nine days. If the slough is not expelled by this time it should be removed with forceps or the finger, provided it is no longer attached to the uterine wall. The procedure is indicated quickly and permanently to destroy infected metrium and endometrium, as in chronic uterine infections that resist milder measures and in puerperal septic metritis; to produce amenorrhea, e.g., when absolute permanency, sterility or eradication of associated uterine infection is desired, in nonmalignant metrorrhagia where destruction of uterine function is desired and in that accompanying advanced pulmonary tuberculosis; as a simple sterilizing procedure in mental and moral defectives, and to eradicate recurrent uterine polyps, submucous fibromyomas and benign interstitial tumors lying close to the endometruim, and recurrent pedunculated tumors of low malignancy.

Incidence of Bacterial Invasion of the Uterus and Its Contents.—F. C. Goldsborough and B. Roman (*Buffalo General Hospital Bulletin,* April, 1924) found that of a series of two hundred consecutive confinements almost twenty-five per cent. showed contamination of the placentas with bacteria. It seems probable that bacteria find their way into the uterus soon after the rupture of the membranes in the vast majority of cases. The longer the duration of labor after the membranes have ruptured, especially if vaginal examinations have been made, the more likely the uterine contents will become markedly contaminated. The question of transmigration of bacteria through the placenta and its effects upon the mother on the one hand and upon the fetus on the other hand, as well as the incidence of this occurrence, will be dealt with in later reports.

Ultraviolet Ray Treatment in Gynecology.—Elsa Sillman-Lönnroth (*Finska Läkaresällskapots Handlinger,* January-February, 1924) narrates her experience in Prof. Wegelius' Clinic at the University of Helsingfors in the treatment of such affections as oophorosalpingitis and parametritis, endometritis, vaginitis, amenorrhea, kraurosis vulvæ, myoma uteri and pruritus vulvæ, the rays from a specially constructed lamp being projected through a vaginal speculum. This artificial heliotherapy proved of value in promoting resorption in subacute and chronic inflammatory processes, while the amenorrhea depending on ovarian dysfunction was not remedied.

The patients were mostly bed cases in the hospital, a few being ambulant. The author gives a résumé of the history of light therapy and ultraviolet rays first used by Finsen, of the various lamps and their later modification for radiation of the genital tract, the apparatus used in her own observations being that constructed by Dr. Landeker (1922) of superior therapeutic efficiency in the intensity of its ultraviolet rays, and similar therapy with the same lamp is quoted from reports by Colombino, Mozzetti-Monterumici and V. Bardeleben. The applications last from a few minutes to one hour and the rays seem directly invigorating. Their bactericidal effect is not demonstrated fully, but in two cases gonococci disappeared after two to four radiations, while for weeks previously cultures had shown their presence. That light therapy favorably influences metabolism and oxidation is the belief of the author and the observers she quotes.

Treatment of Dysmenorrhea and Sterility.—Walther Schmitt (*Zentralblatt für Gynäkologie,* February 16, 1924) obtained the following results: Of 134 women treated for dysmenorrhea, 64.1 per cent. were cured permanently, 18.6 per cent, were cured temporarily or improved and 17.1 per cent. were not improved. Of these, 40.1 per cent. were entirely satisfied with the treatment, 28 per cent. were satisfid and 29.1 per cent. were dissatisfied. Of 81 women treated for sterility, 37 per cent. were cured. The material shows that the acute anteflexion of the uterus and the stenosis of the internal and external os of the cervix of the uterus play an important part in the etiology of dysmenorrhea and sterility. Among the 150 women treated, absolutely normal genitals were found in 28.6 per cent. of the cases, 39.3 per cent. showed a sharp anteflexion of the uterus, 21.3 per cent. showed a stenosis of the internal os and 8 per cent. showed a stenosis of the external os; 2.6 per cent. showed an infantile uterus. Neither the genital findings nor any existing occupational injury, nor the course of the menses had any appreciable effect on the treatment. With the aid of laminaria, curettage and cervical plastics a large part of the dysmenorrhea cases and some cases of sterility may be cured. However, the number of uncured cases is so large that the results are unsatisfactory. In the future the author intends to direct his attention to the factors of constitutional anomalies.

Etiology of Prolapse of the Uterus.—Th. Heynemann (*Zentralblatt für Gynäkologie,* January 19, 1924) believes that some cases of prolapse of the uterus are due preeminently to a constitutional predisposition, as in the cases of prolapse in nulliparæ and in the pronounced asthenias with relaxed musculature and connective tissue, with enteroptosis and the simultaneous existence of hernias and anal prolapse. On the other hand, there are women who seem to be constitutionally normal and in whom prolapse does not occur in spite of severe injuries to the pelvic floor. However, the constitutional predisposition does play an important part in the causation of prolapse, and the conditions are similar to those in which there is relaxation of the abdominal wall after parturition. Marked distention of the abdomen resulting from large fetuses, twins and hydramnios cannot be questioned as a cause of prolapse. Nevertheless, prolapse occurs in relatively healthy women, and in the majority of women particular injuries during and after labor, resulting in distinct injury and relaxation from prolonged labor with large fetuses, surgical procedures in delivery, advanced age in primiparæ and the premature resumption of work and overexhaustion, must be made responsible.

Ovaries and Menstruation. — Eliseo Ramirez says (*Endocrinology,* March, 1924) that not only does the corpus luteum have no function in initiating menstruation, but its presence impedes the menstrual onset. He has been able to demonstrate an antimenorrhagic action of extract of corpus luteum in cases of hemorrhage of ovarian origin. Ovariotomized rabbits injected with an extract of menstrual blood, when their uteri were studied histologically, showed the atrophic changes in the muscular structure characteristic of castration, whereas the mucosa and uterine glands took on the characteristics seen in normal estrus. There was no epithelium covering any part of the surface. The author believes that these experimental estrual changes are due to a lipoid produced by the interstitial cells of the ovary, carried to the uterus, and discharged into the menstrual flow.

Constitutional Significance of Amenorrhea and Its Treatment.—B. Aschner (*Wiener klinische Wochenschrift,* December 20 and 27, 1923) divides amenorrhea into three types: 1, The complete type; 2, the milder form of oligomenorrhea; and 3, opsomenorrhea, which is associated with a prolonged interval of menstruation. Amenorrhea occurs usually in five types of women: 1, in anemic and chlorotic women; 2, in plethoric women, who are benefitted by venesection; 3, in hypoplastic women (universal or partial); 4, in obese women; and 5, in women with hypertrichosis, even though it may be slight. The author favors the theory of the depurative function of menstruation and he even doubts whether climacteric disturbances are not caused by suppression of the menstruation rather than to cessation of the ovarian function. Obese women are occasionally cured of amenorrhea after a process of reduction of the obesity, but there are also cases in which the obesity disappears after the induction of regular menstruation by venesection and local treatment. He found that iron and arsenic might do more harm than good in plethoric women.

Aftereffects of the Late Toxemias of Pregnancy.—John W. Harris (*Bulletin of the Johns Hopkins Hospital,* April, 1924) examined 111 patients who had been suffering from any form of the late toxemias of pregnancy one year following delivery, in order to obtain information as to the ultimate outcome of such complications. The classification of the late toxemias was based on two criteria: the presence or absence of convulsions, and the presence or absence of renal involvement at the end of three weeks following the termination of pregnancy. The cases were divided into four groups: eclampsia, preeclamptic toxemia, nephritic toxemia, with convulsions, and nephritic toxemia without convulsions. The figures indicate that chronic nephritis is a sequel to be reckoned with in women who have had eclampsia, and also that one attack of eclampsia confers at least a relative immunity against its occurrence in subsequent pregnancies. In the patients with preeclamptic toxemia, only twenty-two were normal at the end of the year, and thirty-three showed signs of chronic renal involvement. While the incidence of chronic nephritis was unexpectedly high in both primiparæ and multiparæ, it was twice as great in the latter as in the former. In all the patients with nephritic toxemia, with and without convulsions, at the end of a year, evidences of chronic nephritis were present, this being more severe than when the patient left the hospital. In discussing these findings, it is stated that the length of time the toxemic symptoms have persisted seems to be a factor in determining the occurrence of permanent renal damage. The experience of the author seems to justify the conclusion that, when the signs and symptoms of the toxemia persist for three weeks or longer after delivery, the chances of escaping permanently damaged kidneys are minimal.

Experience with One Thousand Cases of Abortion.—D. S. Hillis (*Surgery, Gynecology and Obstetrics,* January, 1924) gives a tabulated report of the thousand cases and offers the following conclusions: 1. Conservative treatment of abortion in febrile cases gives better results than active therapy. 2. Febrile patients who have a five day afebrile period have a greater tendency to continue a normal temperature after curettage than those who are operated upon before the end of this period. 3. Afebrile patients with a five day observation period have a greater tendency to remain with a normal temperature than do those who are curetted before the end of this rest period. 4. Approximately 6.2 per cent. of patients must be emptied because of alarming hemorrhage. 5. A plan of procedure which embodies a conservative rest period of five days' normal temperature for febrile and afebrile patients and results in as low a mortality as quoted in this paper seems to be a rational method for the treatment of abortion.

Glycosuria of Pregnancy and the Socalled Renal Diabetes.—K. Motzfeldt (*Norsk Magazin for Laegevidenskaben,* September, 1922) reports the case of a woman, twenty-six years of age, who showed glycosuria without any other symptoms of diabetes during two succeeding pregnancies. The sugar excreted in the urine was not influenced by the intake of carbohydrates. The glycosuria disappeared six days after confinement. The frequency of glycosuria during pregnancy is given as four to fifty per cent. The second case, showing a complete recovery from a typical renal diabetes, is supposed to be unique in the literature. As to the genesis the possible rôle of the sympathetic nervous system is suggested by the author. The third case is considered as a condition halfway between renal and ordinary diabetes. The possible relation of the traumatic neurosis to the renal type of diabetes is discussed. The facts upon which the diagnosis of a renal diabetes is based—glycosuria with normal glycemia, little or no relation between carbohydrate intake and glycosuria, absence of diabetic symptoms—can be seen in early cases of ordinary diabetes. As to the pathogenesis of the renal type the author maintains that this may possibly be the same as true diabetes, only that the cases are not progressive, but come to rest at a comparatively early stage of the development.

Results with the Alexander-Adams Operation.—Andreas Kuncz (*Zentralblatt für Gynäkologie,* February 16, 1924) believes that the Alexander-Adams operation is one of the good operations with which the free retrodeviation of the uterus can be cured. The procedure does not take long and the round ligaments are easily found. If the latter are thinned out the thicker intraperitoneal portions should be used. It has cosmetic advantages as the scar is hidden by the pubic hair. It is the most ideal procedure for the physiological restoration of the position of the uterus. If the inguinal canal must be opened, the Bassini method of closure is indicated. The round ligaments should be fastened with silkworm gut. The important elements in this procedure are a good technic, careful incision, dull dissection, avoidance of injury to the bloodvessels and careful hemostasis. This operation is contraindicated in those cases in which the history and examination show the slightest traces of past inflammation in the vicinity of the uterus, in the adnexæ and in the parametrium, and also in obesity. It is very useful in those cases where the uterus can be easily brought into the position of anteflexion, where the pessary test shows the absence of adhesions and where the condition of the adnexæ and appendix do not require careful revision of the abdominal cavity.

Treatment and Prophylaxis of Eclampsia.—Friedrich Heinlein (*Zentralblatt für Gynäkologie,* February 16, 1924) maintains that the individualized and theoretically expectant treatment of eclampsia has many advantages over the purely active therapy: the former shows a maternal mortality of seven per cent. and an infantile mortality of thirteen per cent. as compared with those of the latter, namely 23.3 and twenty-two per cent. respectively. According to the conditions of the individual case, a purely expectant treatment

will suffice ,or later, especially in the interest of the child, a safe delivery will result; in rare cases accouchement forcé will be necessary in rare cases. Cæsarean section is not without danger in these cases. Whether a preliminary venesection several hours before the delivery will render a favorable prognosis in this operation remains to be determined in the future. If the eclampsia is associated with a narrow pelvis, which in itself does not require Cæsarean section, active treatment may be necessary (possibly with preliminary venesection), as a protracted conservative therapy aggravates the eclampsia. The upper limits of the indication with normal blood pressure are determined by the individual factors in the case. Exhausting physical exertion in the late months of pregnancy seem to favor the development of eclampsia.

Primary Repair of the Perineum During the Puerperium.—W. Rudolphson (*Zentralblatt für Gynäkologie,* February 16, 1924) recommends the use of the secondary suture of the perineum after failure of the primary suture for the following reasons: 1. It is always successful, prevents gynecological conditions and avoids later necessary operations. 2. The carrying out of this operation during the woman's first stay in the hospital makes it easier for the woman to make up her mind and spares her time and expense. 3. The contraindications, danger of infection and mishaps with their somatic and mental disadvantages are so rare that they may be neglected. The secondary perineal suture should be done as soon as the temperature is normal and the wound has become clean. According to the author's experiences it is immaterial whether the granulations are curetted off or left in place previous to the application of the suture.

Treatment of Febrile Abortion. — Kurt Laemmle (*Zentralblatt für Gynäkologie,* February 9, 1924) draws the following conclusions: 1. In uncomplicated cases (febrile or afebrile) without marked hemorrhage, the results as regards life and health are about the same with active and expectant treatment. The active treatment shortens the stay in bed, injures the general condition less, and returns the patient sooner to her duties or work. 2. In the presence of a demonstrable transuterine infection, the patient should be treated clinically as far as possible; in the presence of a serious hemorrhage and if the transportation of the patient is impossible, the uterus must be emptied as gently as possible, as the battle of the body against the invading infection is made more difficult by the additional hemorrhage and weakening. 3. The technic of the emptying of the uterus is immaterial, provided it is done gently and by an experienced physician.

Rapidity of Sedimentation of Erythrocytes in Abortion.—G. Frommolt (*Zentralblatt für Gynäkologie,* February 9, 1924) has found that the more marked the acceleration of the sedimentation of the red blood cells in an abortion, the more likely is the course of the abortion to be attended by fever, especially in cases of abortion during the first three months. Accordingly the sedimentation reaction of the erythrocytes is applicable in the determination of the question whether an abortion is infected or not, and it also deserves recognition in determining the indications for treatment.

Uterus Didelphys.—F. C. Newton (*Annals of Surgery,* January, 1924) presents the following summary of his findings on this disease. Four cases of uterus didelphys are reported. This condition, one of the rarer uterine anomalies, is the result of a failure of fusion between the two Müllerian ducts. It is usually unrecognized until pregnancy occurs and is no bar to the successful termination of the latter.

Hemolytic Streptococci in Pregnancy.—A. E. Kanter and I. Pilot (*Surgery, Gynecology and Obstetrics,* January, 1924) give a tabulated report of their bacteriological findings in the vaginal secretions of ninety-six pregnant women, and summarize their findings as follows: The normal vagina rarely contains virulent hemolytic streptococci and there is no evidence that the presence of such streptococci plays any part in the production of puerperal sepsis. 2. Any manipulation of the vagina, either for examination or operative procedure, increases the possibility of puerperal sepsis. 3. Puerperal hemolytic streptococcic infection is regarded in most instances as evidence of exogenous infection. 4. Droplet infection from attendants is possible and the use of gauze masks during delivery and the exclusion of those having sore throat from the delivery room and from attendance on puerperal women is clearly indicated.

Diagnostic Applicability of Phloridzin Glycosuria in Pregnancy.—E. Klaften (*Zentralblatt für Gynäkologie,* April 26, 1924) states that if glycosuria does not appear after the use of a relatively large amount of two milligrams of phloridzin, pregnancy can be excluded with great likelihood, but if one milligram produces a glycosuria the existence of pregnancy must be accepted as very likely. Only twenty-seven per cent. of the cases of early pregnancy are so slightly hypersensitive as to show glycosuria after the use of one milligram and two milligrams appear to be such a large dose as frequently to give a positive result in nonpregnant women. Therefore only the glycosuria that follows a dose of one milligram should be considered as one that indicates a hypersensibility characteristic of the pregnant woman.

Treatment of the Hydrops of Pregnancy.—J. Wieloch (*Zentralblatt für Gynäkologie,* April 26, 1924) was enabled to accomplish a reduction in weight, for a duration of five to eight days, in about half of his cases of hydrops of pregnancy with the use of intramuscular injections of five c. c. of gelatin (five to twenty grams of gum arabic and one hundred c. c. of Ringer's solution, filtered and sterilized). This loss of weight occurred without any other form of therapy and without any change in the mode of living. In some cases it amounted to several kilograms. In two or three cases the increase in blood pressure was brought to a standstill or lowered. The author, therefore, favors the use of the gelatin or gum-Ringer treatment in the therapy of hydrops gravidarum and in the prophylaxis of eclampsia.

Routine Treatment of Asphyxia of the Child During Delivery with Chloroform Anesthesia.—E. Frey (*Zentralblatt für Gynäkologie,* May 3, 1924) found that chloroform anesthesia is not dangerous, but often affords protection to the child against asphyxia by protecting the period of its expulsion and diminishing an excessive pressure. Therefore the anesthesia is indicated in case the fetal heart beats continue to number less than one hundred. If the mother presents the necessary conditions, spontaneous delivery will result in about fifty per cent. of the cases and the use of forceps will not be necessary. If it does not set in within ten to fifteen minutes, there will be plenty of time to complete the delivery under conditions of careful disinfection, in contrast to the otherwise frequent need of haste.

Intrauterine Death of Fetus Carried Past Term.—A. Mayer (*Zentralblatt für Gynäkologie,* January 12, 1924) maintains that the cause of death in fetuses carried past term is most probably to be found in disturbances of metabolism and those of internal secretion. It appears that the abnormally long duration of pregnancy and the intrauterine death of the fetus are preeminently associated with the male sex. This might possibly be attributed to the fact that in the presence of a male fetus greater demands are made upon the metabolic processes of the mother than in the presence of a female fetus. From the viewpoint of internal secretion, special attention should be given to the thyroid gland, the hypophysis, and adrenals in these cases.

Inflation of the Fallopian Tubes.—Hugo Sellheim (*Zentralblatt für Gynäkologie,* March 15, 1924) emphasizes the value of intrauterine, nonoperative inflation of the fallopian tubes to determine their patency. Occasionally, however, it is followed by unfavorable results, such as air embolism. Such dangers may be obviated by the use of a well lubricated catheter without injuring or dilating maneuvres, by avoiding injury of the genitals, by avoiding the test during menstruation, and by continuous auscultation for the intraabdominal escape of air and by ceasing the insufflation as soon as the blowing sound is heard. This test should not be used on the slightest suspicion of infection. The author also calls attention to the value of the sensation felt by the hand controlling the instrument. With these precautions the test is comparatively safe.

Dilatation of Cervical Canal by Artificial Relaxation of Muscle.—Ernest Moser (*Zentralblatt für Gynäkologie,* March 15, 1924) found that he was enabled to dilate the cervical canal by injecting sixty c.c. of a two tenths per cent. solution of eucaine in normal saline solution on each side of the cervix, and then slightly above it. Almost immediate dilatation of the cervic resulted. With this technic he curetted fifty cases without anesthesia, with very little hemorrhage, but with severe pain which lasted for hours. Therefore, it is not applicable to ambulant cases. A perforating rupture of the cervix occurred once.

ANESTHESIA

Anesthesia in Intracranial Surgery. — Z. Mennell (*American Journal of Surgery,* April, 1924) says that from a wide experience of over four hundred brain tumor cases he unhesitatingly chooses ether at the present time as the best anesthetic for employment in cerebral surgery, and ether given by the intratracheal method in the vast majority. He lays claim to nothing original for the intratracheal apparatus he uses. The machine is easily portable, and the motor will run on any constant alternating current from eighty to two hundred and forty volts. It has run for eighteen hours on end without getting hot. He uses a two way stopcock when giving ether and oxygen. There is no need to warm the vapor, as the tubes are long, and the temperature of the vapor is that of the theater by the time it reaches the patient. One of the main objects to be aimed at, he says, is that of giving a constant dose, and in these cases especially, the minimal dose which is compatible with efficiency. Any change in the strength of the vapor must be extremely gradual. A free air way, a plentiful supply of oxygen, and a very close cooperation between the surgeon and anesthetist are essential.

Regional Anesthesia in Gynecology.—W. R. Meeker and B. E. Bonar (*Surgery, Gynecology and Obstetrics,* December, 1923) present a comprehensive study of local anesthesia, discussing various methods, sacral nerve block, parasacral nerve block, injections into the perineum, etc. They report on a series of obstetrical cases and sum up their findings as follows.

The preliminary administration of pantopon and scopolamine in proper amount contributes in establishing favorable conditions, but the stage of twilight sleep should not be reached.

The more supérficial operations on the vulva, perineum, and anus may be quite satisfactorily performed under terminal infiltration. Such operations include the removal of cysts and solid benign tumors of the labia majora and minora, superficial fistulæ, perineorrhaphy, surgery of the terminal rectum, and the removal of cervical polypi.

The foregoing operations may be painlessly performed in by far the greater number of cases by block of the sacral nerves by injection of an anesthetic medium into the sacral canal, called epidural, sacral, extradural, and caudal anesthesia. If one who uses this method is willing to supplement the failures by local infiltration, it does not work so much of a hardship. The height of anesthesia by this method is variable, although in a majority of cases anesthesia of the entire pelvic floor and viscera is produced. Its chief use, in addition to the more superficial operations on the external genitalia, perineum, and terminal rectum, is in dilatation and curettage and urological manipulative work.

For the deeper operations on the pelvic floor and viscera the local anesthetic procedure of choice is the association of a low epidural injection with transsacral block of the upper four sacral nerves. This procedure gives a uniformly satisfactory anesthesia in surgery of the pelvic floor and viscera by the perineal route. It has been found sufficient for posterior resections of the carcinomatous rectum, both the single and second stage resections, the posterior wall of the vagina often being removed with the growth. Excision of multiple perineal fistulæ and malignant growths of the vulva and vagina, perineorrphaphy, anterior colporrhaphy, repair of vesicovaginal and rectovaginal fistulæ vaginectomy, amputation of the cervix, the Watkins interposition operation, vaginal hysterectomy, and excision of the carcinomatous urethra, have been painlessly performed under this anesthesia. Resection of the bladder may be painlessly performed when field block is added for the suprapubic incision.

The borderline of usefulness of the transsacral method is seen in the posterior resection of a high lying carcinoma of the rectum, or rectosigmoid, the Watkins interposition operation, and the Mayo vaginal hysterectomy. Here the traction necessary in delivering the viscus into the operative field is often transmitted outside of the anesthetized area and produces pain. This traction pain cannot be controlled by paravertebral nerve block, but, when it is necessary, a short primary ether narcosis, or nitrous oxide oxygen analgesia should be administered at this point.

Parametric injections do not efficiently control the traction pain of surgical manipulation in vaginal hysterectomy, and anesthesia of the vagina, also, is usually necessary.

Local anesthesia in pelvic operations by the abdominal route is sufficient for the laparotomy, but general narcosis is usually necessary for the pelvic work. For most surgeons of wide experience, local anesthesia, by whatever method induced, does not create an operative condition compatible with the employment of the surgical methods indicated by most pathological conditions of the pelvis.

In obstetrics the epidural method is more practical than the transsacral, although block of the lower four sacral nerves by the latter technic, with the aid of a low epidural injection, gives satisfactory anesthesia. A great advantage of the method is the relaxation of the pelvic floor, which is more complete than with any other anesthesia.

The forceps operation, version and extraction, manual dilatation of the cervix, rotation and repair of cervical and perineal tears may all be painlessly performed by epidural anesthesia, which may also be used in the removal of uterine contents in incomplete abortions, packing of the uterus, and in insertion of the colpeurynter.

The pains of normal labor may be controlled by this method, although the abolition of the pain reflex also takes away the voluntary effort of bearing down. Uterine contractions continue, however, so that if the parturient is instructed when and how to bear down, completion of labor occurs painlessly.

The feature of greatest difficulty is in the selection of the proper time to induce anesthesia. Most cases could be made to terminate painlessly if the anesthesia could be administered an hour to an hour and a half before delivery. In our experience, the maximal value of the anesthesia results when not given until the os has reached at least seven centimetres dilatation in primiparæ and at least four centimetres in multiparæ for average cases.

The field of usefulness in spontaneous delivery will greatly increase when a means has been devised to prolong the action of an epidural injection. Further investigation is necessary on this subject. It is possible that the drugs are already at hand, the proper combination and use of which will anesthetize the entire pelvic floor and viscera for five or six hours without repetition. Such an anesthetic should prove a great blessing in obstetrics and become the anesthetic of choice in normal delivery.

Anesthesia in Bad Operative Risks.—E. A. Tyler (*American Journal of Surgery,* April, 1924) gives the following anesthesia treatment for cases of damaged myocardium and hyperthyroidism:

One of the most frequent complicating factors for a successful operation is a damaged myocardium. Reeently we have been able, by the proper use of digitalis tincture, over a period of a few days to a month, to prepare a seriously damaged heart muscle so that it has successfully withstood one, and frequently two to three operations. It has been our custom to start the patient on ten minims of the fat free tincture of digitalis three times a day. We rarely go above this dose, but prefer rather to spread the dose over a longer period of preparation. This is given until we are able to slow the heart rate down to ninety at least, or preferably eighty, if that can be accomplished. It has been our observation that the blood pressure ratio does not seem to improve materially under this treatment, so that we have had to ignore this guide in determining the time for operation. Besides the pulse rate we have been able to use the electrocardiograph in some few cases to determine when digitalis saturation has been reached.

This treatment is of special value in patients suffering from hyperthyroidism, who, as is well known, often exhibit concomitant damaged myocardia. We have also found digitalis of real value in at least seventy-five per cent. of the patients presenting themselves for prostatectomy.

Another of our sheet anchors in the bad operative risks is morphine. This drug has a very salutary effect in patients with weak hearts, because it lessens the drive of fear on an already overworked heart. We give one or more doses of morphine plain, or morphine and scopolamine, or morphine and atropine, so that the patient is somewhat "dopy," thus alleviating fear. This has enabled us often to take a nervous patient to the operating room with a pulse rate of seventy-two to eighty-four, and frequently not have the pulse rate exceed this throughout the operation. In cases of hyperthyroidism; we believe it to be criminal to operate without morphine. These patients can tolerate large doses of morphine on account of their high metabolic rate; the morphine also helps to decrease the metabolism.

Intravenous Anesthesia. — A. Lehrnbecher (*American Journal of Surgery,* January, 1924) reports on nine hundred cases of intravenous anesthesia, and cites two special indications for its use as follows: 1. In operations in the region of the head and neck it is very convenient, as the operator and anesthetist are separated from each other and are not hindering each other. Complete asepsis is certainly less endangered by this method. 2. Intravenous anesthesia has a very beneficial effect in all cases, in which infusion of saline is indicated. In such patients it is the method of choice, not equalled by any other. When an operation has to be done on persons who are in a state of deep shock, or who have lost much blood, the patients leave the table in a far better condition than before, thanks to the infusion. It is of extreme value in cases of ectopic pregnancy with intra-abdominal hemorrhage. Here the reinfusion of the lost blood may be combined with the infusion of Ringer solution. In cases of advanced peritonitis the infusion prevents the further fall of the blood pressure.

He concludes that further experience will show whether it is possible to improve the method. Pharmacological research work may perhaps succeed in finding a drug which has no damaging effect on the heart and on other organs. Then we shall have a really ideal method. The width of choice may be very great, as only sufficient solubility is necessary, and as no volatility, as for inhalation anesthesia, is required. Burckhardt experimented with quite a number of drugs. It seems likely that the method of intravenous anesthesia will be of great interest in America especially, where knowledge and the research in the field of anesthesia are so highly developed. It may become a routine method for those who specialize in the administration of anesthetics.

Spinal Anesthesia.—A. G. Rytina and H. L. Tolson (*Annals of Surgery,* February, 1924) say that in their experience with 387 cases in which operation was performed under spinal anesthesia, they noted the following advantages of the method:

The anesthetic is quickly and, in most cases, readily induced. Operative shock is avoided by the blocking of the nerve supply of the operating field. Hemorrhage is less than with inhalation anesthesia. Perfect muscular relaxation is a decided advantage in abdominal surgery. A smaller incision may be made and less traction is necessary than with inhalation or local anesthesia. Contraction of the intestines allows ready inspection of the abdominal viscera and very little packing off is required. The time allowed by spinal anesthesia is conducive to more careful work. No injury to the kidneys occurs with spinal anesthesia. The heart is disturbed less than with inhalation anesthesia. Gastric disturbances occur in only a small percentage of cases and are then slight and transitory. Liquids may be administered by mouth during and immediately after operation. Nourishment may be given just after the disappearance of the analgesia effect. Convalescence is shortened and there are few postoperative complications attributable to the anesthetic. No lasting postoperative effects due to the anesthetic have occurred in our cases. Spinal anesthesia is a safe method as regards danger to life. In brief, spinal anesthesia is a method which permits the performance of operative procedures without disturbing the equilibrium of the patient.

Pure Nitrous Oxide Oxygen Anesthesia.—E. I. McKesson (*American Journal of Surgery,* April, 1924) asserts that nitrous oxide oxygen anesthesia possesses many properties, which particularly adapt it to the field of oral and sinus surgery, and although it has not yet reached the place in rhinology that belongs to it, the fault has not been in its adaptability, but in a lack of knowledge of the mode of administration and its advantages for this work. Anesthesia, for all sinus surgery, whether done through the nose or mouth, is performed under the same general principle of pressure administration. There are only two contraindications to the use of gas oxygen, first, the want of an apparatus capable of meeting the physiological, the operative, and the mechanical requirements, and second, a lack of knowledge on the part of the operator and anesthetist. The author believes that no one has shown that gas oxygen directly or indirectly retards the healing processes after an operation, and upon the basis pointed out in another paper, it is reasonable to conclude that structural changes in any tissue may not result from its use. In this respect, it differs from other anesthetics, local as well as general, and this characteristic, together with other properties, makes it preferable for any operation requiring an anesthetic.

There must be the mechanical equipment for maintaining an adequate pressure of the gases at the inhaler with an enormous range of gas delivery to maintain this pressure, under the variable conditions of the respirations and the respiratory passages, if we are to be able to anesthetize all types of cases for oral surgery. A patient, who is not sufficiently narcotized by the usual induction or primary saturation, may relax if merely given more time in which to become saturated, but many of these cases require a more definite procedure—they require secondary saturation and because of their frequent tendency to large, quick inspirations, more than the usual care is needed to exclude air from the air passages, by administering the gases at a higher pressure than usual.

Secondary saturation consists of two procedures: 1, administering pure nitrous oxide until sign of approaching fourth stage anesthesia develop; 2, in following at the next inhalation with one or two breaths of from twenty to one hundred per cent. oxygen to correct the anoxemia, then continuing by the administration of such a mixture of nitrous oxide oxygen as will maintain narcosis, without well developed signs of anoxemia. Of course, this presupposes instant and absolute control of the two gases, mechanically.

Paravertebral Anesthesia in Kidney Surgery.—G. Kolischer (*Surgery, Gynecology and Obstetrics,* June, 1924) believes that paravertebral nerve block, conducted by a proper technic, furnishes in practically every instance a satisfactory anesthesia. There is no mortality produced by a paravertebral anesthesia. It is applicable in all renal and ureteral surgery executed through the retroperitoneal route. The method which he described has been almost universally satisfactorily employed by him and other American surgeons in about seven hundred cases, with four failures only, and these, without any prejudice, may be ascribed to the extreme neurotic condition of the patients.

Paravertebral anesthesia is particularly indicated in renal surgery when the patient to be operated upon is suffering from pulmonary, circulatory, or bilateral renal disorders. It is contraindicated in infants and when it is necessary to perform the operation through the transperitoneal route. The disagreeable and dangerous aftereffects of general anesthesia as shock, nausea, vomiting, aspiration pneumonia, and anuria acidosis, and those of spinal anesthesia, as malaise, temporary paralysis or even *exitus letalis,* are done away with in paravertebral anesthesia. The technic is simple and easily acquired and mastered.

Ethylene Anesthesia.—W. E. Brown (*American Journal of Surgery,* January, 1924) records the results from his report on several cases. The descriptions of all these subjects, several of whom were entirely ignorant of the gases used, agreed that while nitrous oxide oxygen alone produced pounding or whirling sensations with a definite period of dizziness subsequent to removal of the anesthetic, and that the sensations were somewhat unpleasant, nitrous oxide and ethylene were distinctly more pleasant. There was a general feeling of numbness, little pounding or fullness in the head, a more marked feeling of "fading away" and less subsequent dizziness. Pain sensations were also much more definitely dulled or in some cases absent. There seems no doubt that a much greater percentage of oxygen can be used. We have found our inductions to run at about ninety and maintenance eighty-five to eighty per cent. ethylene. There is no cyanosis and good relaxation. There is often some slight nausea following the anesthetic, but it is not prolonged. There seems to be no irritation to the lungs or kidneys, and these facts together with the fact that C_2H_4 can be purchased for about one third the cost of N_2O seems to point to its early adoption as a routine anesthetic.

Sacral Anesthesia.—E. C. Brenner (*Annals of Surgery,* January, 1924) offers the following conclusions: Sacral anesthesia, if properly administered, is a safe procedure and should not be confounded with spinal anesthesia. The motor nerves are not affected and the three lower sacral sensory nerves are those chiefly anesthetized by conduction. With proper technic successful anesthesia will result in the majority of cases. Failures grow less as one becomes more experienced. It would seem that sacral anesthesia is deserving of more general application in rectal, genitourinary and perineal surgery. One should be familiar with the technic of transsacral conduction in case of failure of the caudal bloc.

Medicolegal Notes.

INJURY AGGRAVATING TUBERCULOUS DISEASE COMPENSABLE

The Kentucky Court of Appeals holds that the provision in the State Workmen's Compensation Act that personal injury by accident shall not include "the results of a preexisting disease" does not exclude from compensation the results of the accident. It merely excludes the results of the preexisting disease. The results are the ordinary and natural consequences of the disease itself, and do not include those consequences which would not have followed if there had been no accidents. The applicant, though afflicted with tuberculosis of the spine, had been in the employer's employ for about five years, and had worked practically every day until the time of the accident. From that time on his condition grew worse, and at the end of six months he was totally disabled. The Workmen's Compensation Board found upon substantial evidence that his disease had lain dormant until the accident, and that the accident "lighted it up." Doubtless in time the disease would have wholly incapacitated the applicant for work; but if, before that time arrived, the disease was aggravated or accelerated by the accident, and he was thereby disabled sooner or to a greater extent than he would have been had it not been for the accident, there was an additional injury that was not the result of the disease but of the accident, and such injury was held to be compensable to the extent of the disability due to the accident. The Legislature did not intend to discriminate between employees who were well and those who were suffering from a preexisting disease, but merely that the employer should not bear the burden of the results that would have followed from the preexisting disease if no accident had occurred.—Robinson-Pettet Co. v. Workmen's Compensation Board (Ky.), 258 S. W. 318.

PLAINTIFF TO SHOW WANT OF CARE, SKILL, OR DILIGENCE

The Georgia Court of Appeals holds, Martin v. Greer, 121 S. E. 688, that a person professing to practice surgery or the administering of medicine for a compensation must bring to the exercise of his profession a reasonable degree of care and skill (Ga. Civil Code, 1910, §4427). In a suit for damages alleged to have been caused by the malpractice of a surgeon, the burden is on the plaintiff to show a want of due care, skill or diligence, and also that the injury resulted from the want of such care, skill or diligence.

Where the petition in such a suit failed to show any negligent exercise or failure to exercise any professional act or duty owed by the defendant as a surgeon in sending the plaintiff to the city hospital; or any negligence chargeable to the defendant in the performance there by others of the operation in setting a broken leg; or in any subsequent treatment by the defendant, it was held the trial court did not err in sustaining a general demurrer to the petition.

Under the rule that it is improper to plead evidential facts, it was held that the inclusion in a petition, or the attachment thereto as an exhibit, of an x ray photograph, designed to show the condition of an injured member from the alleged malpractice, is subject to special demurrer. The court followed Pace v. Cochran, 144 Ga. 261, where the photograph "of the present condition" of a broken arm alleged to have been negligently set was held improperly attached to the petition.

ACT AUTHORIZING ISSUE OF TOWNSHIP BONDS FOR ERECTION OF HOSPITAL HELD CONSTITUTIONAL

The South Carolina Supreme Court holds, Battle v. Willcox, 122 S. E. 516, that the Act of March 26, 1923, authorizing the board of commissioners of Marion county to issue and sell bonds to purchase a site and erect and equip a hospital in Reaves township is valid and constitutional as against the following contentions: 1. That the act was in contravention of section 5 of article 10 of the State Constitution of 1895, in that the bonds were not sought to be issued for a corporate purpose. Since the corporate purpose of a township is primarily to perform such governmental functions as may be committed to it by the General Assembly, in delegating to Reaves township the power to erect and maintain a public hospital the General Assembly conferred a power which was for a corporate purpose within the meaning of the section of the Constitution. 2. That the act was in contravention of section 6, article 10, of the Constitution, in that the hospital building was not such a "public building" as is contemplated by that section. 3. That the act was in contravention of subd. 3, section 34 of article 3 of the Constitution in that it was an attempt to incorporate and create a hospital by special law. Two judges dissented on the ground that the act provided that the commissioners might lease the hospital to other parties, so that it might at once be converted into a private hospital, and entirely free from the management of the public officials.

COMPENSATION FOR PERMANENT DISABILITY FOR INJURY TO EYE

The California courts hold, Globe Cotton Oil Mills v. Industrial Accident Commission, (Cal. App.), 221 Pac. 658, that where for an injury causing the necessary removal of the lens of a workman's eye, in which condition he had but 1/100 vision, owing to the fact that he had previously entirely lost the sight in his remaining eye, the Commission determined the percentage of permanent disability was 19¼ per cent., such award was within the Commission's discretion, although with the aid of properly prepared and adjusted glasses applicant's sight was restored to practically normal vision. This is a matter on which experts of equal experience may differ greatly in their conclusions.

EVIDENCE AS TO TREATMENT OF SIMILAR CASES HELD INADMISSIBLE

In an action for damages for injuries suffered in a treatment for cancer of the eyelid by one not licensed to practice medicine, the Oklahoma Supreme Court holds, Ragan v. Shannon, 225 Pac. 672, that it was error to admit testimony of witnesses that they at one time had cancer and that defendant had cured them, there being no connection between this evidence and the diagnosis and treatment of the red spot on plaintiff's eyelid, and, the witnesses being all non-experts, their evidence was purely opinionative as to whether they had cancer.

PHYSICIAN MAY TESTIFY AS TO CONSENSUS OF MEDICAL OPINION AS TO THE THERAPEUTIC VALUE OF DRUGS.

In a libel for misbranding packages of pills, in violation of section 8 of the Federal Food or Drug Act, in regard to the curative properties of the pills, the Circuit Court of Appeals, District of Columbia, holds, United States v. Chichester Chemical Co., 298 Fed. 829, that a medical witness may testify as to the consensus of medical opinion, if any there was, in respect to the therapeutic properties of the ingredients of the pills. This rule, the court said, doubtless rests in part upon the view that Congress did not intend by the act to condemn honest differences of opinion between different medical schools relative to the therapeutic value of drugs in the practice of medicine.

Trustworthy!

The extent to which innumerable practitioners of medicine are today employing

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

whenever a dependable reconstructive tonic is called for, tells in no uncertain way of its therapeutic utility and gratifying efficiency.

During the thirty-five years this reliable tonic has been at the service of the profession, the quality of its ingredients and the unvarying character of the composite product have been consistently and faithfully maintained.

Thus it is easy to understand why the host of medical men who have learned how reliable it is in its character and results, not only take pains to order the original Gray's Glycerine Tonic Comp. (P. F. Co.), but also to see that their patients get no other!

Such care is well worth while, for it often measures the difference between success and failure.

The Purdue Frederick Co., 135 Christopher St., New York

Valentine's Meat-Juice

In **Hospital** and **Private Practice** and **in their own persons** when ill, **Physicians** have demonstrated the **Power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** the **Weakened Vital Forces** when the **Digestive Organs** are **Impaired.**

Debility, Exhaustion *and* Anaemia.

Dr. Julian Calleja, *Pres. Royal Academy of Medicine of Madrid, Spain:* "It is with the greatest satisfaction I inform you that I consider VALENTINE'S PREPARATION OF MEAT-JUICE to be of a very superior order for invigorating the nervous system, for which I use it myself and prescribe it to my patients."

John Tanner, M. D., LL. D., *Senior Physician Farringdon General Dispensary for Diseases of Women and Children, London, England:* "In cases of Flooding or Hemorrhage of any kind, Fevers, low forms of Pneumonia, Extreme Exhaustion when the stomach is too irritable to retain any ordinary preparation, then VALENTINE'S MEAT-JUICE will be found to be a perfect God-send. I cannot speak too highly of it, as I have found it of such immense advantage to me in the treatment of the most anxious and serious cases under my care."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S
PREPARATION
NUTRIO PERMIC
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Fads in Health Legislation.—Dr. Morris Fishbein (*American Mercury*, September, 1924) opens his article with a story of a group of physicians returning in a pullman from a medical convention. So deeply were they engrossed in conversation, that the porter waiting with his clothes brush began to fear that he would not have time before the destination was reached to perform his perfunctory duties and collect his tips. So approaching one of the group, he enquired, "Bresh you off, sah?" "No indeed," replied the doctor, "I don't want to fill all this air with bacteria." "Don't be afraid, sah," was the response. "The kind of brushin' I do ain' gwine disturb no bacteria none." With this as a text, Dr. Fishbein goes on to tell us that much of our health legislation is as ineffective as the porter's brush, and quotes examples.

In 1832, at the time the cholera epidemic occurred, the Board of Health at Washington passed a law cutting off entirely the supply of fresh vegetables except potatoes, beets, tomatoes and onions, and cast discredit on these. They then recommended that all theatrical performances and other exhibitions be suspended; then, most astonishingly, passed resolutions that quarantine regulations interdicting the commercial intercourse of the country were wholly ineffectual in preventing the introduction and spread of Asiatic cholera, etc., etc., so it was earnestly desired that no more prohibitory regulations be enacted upon this subject.

In 1916 the State of Colorado passed a law regarding the hygiene of food manufacture and distribution, in which was a clause providing for cuspidors whenever and wherever needed, with directions, albeit, for daily cleansing. "What indeed," comments Dr. Fishbein, "is the presence of the spittoon but a psychological encouragement to spitting?" After quoting a few more rather meaningless regulations about barber shops in Colorado, the writer quotes a soda fountain law in Alabama that "no patron or customer shall be supplied with a spoon . . . except it has been sterilized since last used, or has never been used." Arizona has a law which states that the "midwife must endeavor to secure the assistance of a physician if the child is not born after twenty-four hours of labor." "Why not twelve or eighteen? And if twenty-four is safe, why not thirty-six?" asks the author. Florida forbids the provision of a brush and comb in pullmans, compelling the passenger to tip the porter to produce a bootleg comb from the receptacle in which he has conveniently concealed it. It also requires the cleaning of telephone earpieces and mouthpieces at least once a week, although there is not the slightest scientific evidence that disease has ever been transmitted by these appliances.

Illinois and the State of Washington have passed some very remarkable influenza prevention laws, including the wearing of gauze masks in public during epidemics in the latter State. Dakota has a hotel inspection act that covers almost every sanitary contingent. Texas requires that every hotel must provide sheets long enough to tuck two feet under the mattress at both head and foot of the bed.

After some biting comments on the foolishness, backwardness and laxness of some of our birth registration laws, Dr. Fishbein closes his discussion with the lack of uniformity and discordance of our State laws regulating the practice of medicine. He quotes Connecticut's law entitled *Concerning the Practice of Naturopathy*, adding that it inflicts on the people of the State "all the fantastic forms of assault upon the exterior of the ailing human that have been devised by the paranoiac brains of a hundred cultist prophets . . . most other States, perhaps a little more wary, provide only for the groups with effective lobbies." Physicians who have watched for years the progress of venereal disease legislation, have come to the conclusion that the problem is not a legal but an educational and medical one. "The only value of much of the legislation so far enacted lies in its dissemination of educational matter."

Nebraska, Wisconsin, and many other States have laws forbidding physicians to split fees, and a strong organization of surgeons requires each of its members to take an oath that he will not do so. "But only an elementary knowledge of human nature is required to make it plain that the man who wants to split fees will not hesitate to violate a law that is easier to flout than the Volstead Act, or to break an oath of the nature of that required by the surgical organization."

The article closes with a discussion of the Shepherd-Towner Act passed by Congress to provide for the "public protection of maternity and infancy," and its use, in the writer's opinion, by politicians to capture the women's vote, and for other political ends.

Many—perhaps even some physicians—will disagree with some of Dr. Fishbein's deductions, but he is right in the main, and the material that he presents for our perusal is at least controversial and most interesting.

Feats of Memory.—Some remarkable stories are told of the prodigious feats of memory of the late John Henry Blackburne, says the *Medical Press*, October 15, 1924. It has to be remembered that the blindfold player, from start to finish, neither sees the chessboard nor takes any notes of the game. On one occasion, while playing eight opponents blindfold, Blackburne on ascertaining his opponent's move, immediately and correctly called "mate in four," a feat of which an average player playing a single game over the board might well be proud—yet Blackburne was able to accomplish it while playing against eight invisible opponents!

On another occasion, when engaging ten such opponents, he called a move which, as the pieces stood, was impossible. When told of this he gave the position of every piece on the board, but this did not tally with the actual position. Thereupon he cited each one of some forty moves that had been made on the board and the record of the game proved him to be correct, and that his opponent had not moved his pieces correctly. This showed that the great player must have retained a perfect memory of some hundreds of moves in the course of the ten games.

Even more astounding feats of memory have been recorded. One player is said to have played blindfold twenty games of chess, four games of draughts, while indulging in an ordinary game of whist!

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

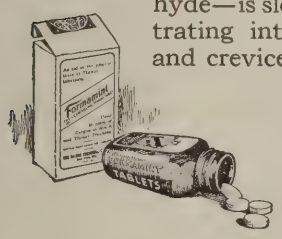
A germicide exerting *continuous action* in the oral cavity

MEMBERS of the profession appreciate the difficulties of successful treatment in tonsillitis or infection of the mouth or throat cavity, because of the usual lack of continuous action on the part of the therapeutic agent.

Formamint, being in tablet form, helps to overcome this difficulty. As the tablet dissolves and disintegrates its main germicidal element—formaldehyde—is slowly liberated, penetrating into the minute folds and crevices of the mouth and throat. This germicidal action can be renewed at frequent enough intervals to make the treatment continuous.

Formamint tablets are harmless and pleasant to the taste. Their convenience of administration renders them a welcome and dependable agent for disinfecting the mouth and throat and maintaining oral prophylaxis.

We shall be pleased to place at the disposal of any member of the profession enough samples for a thorough test. Address: The Bauer Chemical Co., 113 West 18th Street, New York City.



Formamint
GERM-KILLING THROAT TABLETS

Correspondence Course in Public Health Nursing.—The third annual correspondence course in public health nursing given by the University and Bellevue Hospital Medical College in cooperation with the New York State Department of Health is now open for enrollment of students. The syllabus of the course has been entirely reorganized. "Practical Objectives in Health Work During the Next Twenty Years," as outlined by the late Dr. Hermann M. Biggs in his last public address, is the theme running through the entire course of approximately thirty lessons of ten hours each. The various considerations which must not only receive the attention of public health officials and lay workers, but in which the support and cooperation of the public at large must be secured, are taken up in the lessons in connection with the objective under discussion. The intent has been to enable the nurse, through these lessons, to see more clearly the adaptation which she will need to make in her work in order that she may seize the opportunities open to her to aid in attaining these objectives. A residence week of study at some one of the larger medical centres of the State is required during the course.

"One serious handicap"—quoting Dr. Biggs—"to the accomplishment of these ends in the future, in my judgment, will be the lack of a sufficient number of well trained and qualified physicians and public health workers, and their proper distribution." The qualifications of public health nurses in this State (outside of New York City) "appointed after January 1, 1925, by public health authorities," as established by the Public Health Council of the State require that, in addition to being (1) "not less than twenty-one years of age at the time of their appointment" and (2) being "registered nurses," they (3) "shall have completed a course in public health nursing approved by the Public Health Council." The correspondence course announced above is one of those approved by the Council.

Industrial Psychology.—A four hour day in industry would be possible if workers were placed in work for which they are best fitted, was concluded by Dr. Donald A. Laird, of Colgate University, in an address on industrial psychology before the New York City Chapter of the National Association of Cost Accountants on November 11th.

The differences in human abilities are amazing, Dr. Laird said, one coal miner loading twelve times as much coal as another, while it is not rare for one salesman to sell three hundred and fifty times as much goods as another. In every occupation there are usually many workers with twice the abilities of others. Practice and training, Dr. Laird showed, increase these differences rather than lessen them. They are not caused by unequal opportunities but in most instances by the workers' inheritance. A worker may have low ability for one type of work but high ability for another, just as Patrick Henry was a fiery orator but could not write an intelligible report. Every plant should be combed for employees with low ability and those found transferred to work for which they have more ability. In one printing plant this was done and as a result the force was reduced from nine hundred to five hundred. This was accomplished by filling vacancies caused by death and quitting by transferring low producers into work for which they were better fitted.

Psychological tests are available to measure many different abilities and other tests are being developed so it will soon be possible to know accurately what work each should be in. When this is accomplished Dr. Laird stated that hours of labor could be greatly reduced, costs of manufacture and living would be lowered, and many labor problems would be practically annihilated. Nation wide cooperation among American industries will bring this about.

A Mental Prophylaxis Clinic in Paris.—An interesting clinic has been established in Paris by the *Ligue d'Hygiène Mentale* under the care of a well known psychiatrist, Dr. Toulouse. Although originally founded nearly three years ago, the clinic may be said to be still in the experimental stage, for it is constantly developing along new lines and exploring fresh fields for its work in preventing, where possible, mental disease.

The clinic consists, in the first place, of an outpatient department to which patients may come without any formality and where they receive advice gratuitously concerning early symptoms of mental breakdown, such as excessive lassitude, peculiarities and dislikes, delusions and obsessions of all varieties. Although the building in which the clinic is housed is situated in the grounds of an asylum, the patients enter by a separate door and Dr. Toulouse considers that there are advantages to be gained by such an arrangement. The patients receive a complete physical as well as psychical examination; special departments exist to deal with disorders of the eye, the ear, nose and throat, and other organs, and a well equipped laboratory enables the psychiatrist to obtain the aid of all modern diagnostic methods.

In addition to the outpatient department there are wards of two categories. The first, socalled free wards, are for patients with slight nervous symptoms. In connection with these are brightly decorated dining and sitting rooms, and the patients coming from working class homes find themselves in a pleasantly changed environment.

The other class of wards are closed in the sense that there is a certain amount of restraint. Patients who are not definitely insane can nevertheless be closely watched and observed. Should definite symptoms of insanity supervene, the patients can be transferred to an asylum, but a preliminary period of observation, such as is provided by these wards, saves a certain number of persons from the unjustifiable but nevertheless existant stigma of detention in an asylum.

A followup service is being developed and projects are on foot for establishing a system analogous to the Grancher system for tuberculosis, to deal with children who are growing up in a bad mental environment.

Such a service of mental prophylaxis marks a great advance in dealing with mental disease, and it is hoped that similar services will be established in other parts of the world, for only in this way can an effective front be presented to the ever increasing tide of mental breakdown.—(*The World's Health*, October, 1924.)

An Effective Remedy *for* Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Disasters and the American Red Cross.—Statistics compiled by the American Red Cross show that this has been a record breaking year for disasters. In a recent bulletin from Washington we are told that the first half of 1924 shows a record of more disasters drawing upon the relief resources of the American Red Cross than in any similar period in its history. Assistance from Red Cross funds to the victims has been extended in nôt less than thirty-five localities. Floods, tornadoes, explosions, fires and epidemics in the United States and earthquakes in foreign lands called for $200,000 direct from the national Red Cross treasury, while Red Cross Chapters and individuals contributed to relief work much more than that amount.

In addition to these major operations there were numerous smaller disasters for which relief was given by the local Red Cross Chapter without assistance from National Headquarters. The Red Cross is still carrying out an extensive work of relief and reconstruction among the victims of the Lorain, Ohio, tornado of June 28, where the sum of nearly $500,000 has already been raised and more is in sight for the reestablishment of the stricken territory and its people. Forty trained Red Cross workers are covering the entire tornado area and attending to every emergency need of the people who survived.

The disaster in Ohio caused the most widespread destruction of any listed by the Red Cross this year, although other calamities of the half year have recorded greater death lists. Relief activities of the Red Cross were almost wholly confined to the United States, except for earthquakes in Ecuador, Costa Rica and Colombia, and relief of famine sufferers in Albania.

The list of disasters from January 1 to June 30, 1924, where human suffering was relieved by the Red Cross, is as follows:

Tornadoes: South Carolina, Chatham country, N. C.; Martin county, N. C.; Harris county, Ga.; Meriwether county, Ga.; Tunica, Miss.; Eastern Oklahoma, and Lorain, Ohio; Shawnee, Okla.; Mississippi; Marion county, Ala.; Cascade county, Mont.

Cloudburst: Carter country, Tenn.

Windstorms: Dickinson, N. D., and sections of South Dakota, also in Minnesota.

Floods: Crosby, Minn. (mine); Cumberland, Md.; Belle Fouche, S. D.; Bitter Creek, Wyo.; Harpers Ferry, W. Va.

Explosions: Pekin, Ill. (starch works); Johnson City, Ill.; Welch, W. Va. (mine); Benwood, W. Va. (mine).

Fires: Lindonville, Vt.; Montpelier, Vt.; Kalama, Wash.

The Red Cross also extended assistance in funds and trained workers at a serious typhoid epidemic in Lincoln Memorial University, Tenn., and during the Arizona quarantine against foot and mouth disease. The North Carolina and Ohio tornadoes called out the new Mobile Disaster Relief Unit recently organized by the American Red Cross, which responded at once with trained disaster relief administrators and workers and gave relief immediately where calls were most urgent. It is noteworthy of this year's disasters that localities not commonly subject to nature's wrath have been visited by calamity. Most of the disasters occurred east of the Mississippi.—(*The World's Health*, October, 1924.)

When Should a Doctor Retire from Practice?

ROBERT T. MORRIS, M.D.
New York

Alexander Von Humboldt comprehended all of the natural sciences. Today there is no living man who can write a comprehensive geology.

In 1832 Liebig had to go to France to study chemistry with Gay Lussac and others because the Germans were not far advanced in that subject.

No one man today can comprehend all that is known in any one department of surgery. Whenever I go to the Academy of Medicine library in order to look up points noted by my secretary or by professional readers employed for the purpose I am deeply impressed by that fact.

Other surgeons are familiar with procedures of which I know little or nothing and I am familiar with points not as yet generally accepted by the profession. Such being the case, and here is the point, the question arises if any doctor has the moral right to retire when his teaching of certain principles means a saving of life and relief of suffering which otherwise cannot well be accomplished.

Personally I would like to retire from practice in surgery right now and to devote my next fifteen or twenty years to the development of a field in horticulture in which almost explosive advances are being made. Incidentally there would be freedom for going trout fishing on the right days when the wind is in the South, the days when emergency cases come while one is engaged professionally. What are the first duties in a situation of this sort? That is the question.

When I entered the field of antiseptic and aseptic surgery at a time of violent controversy over the values contained in this new departure there were few others in this country or in most of the other civilized countries who had become interested. Many hands rapidly made light work, however, of the principles of this third era in surgery which was new at the time. (The first surgical era was heroic, the second anatomical.) In the third or pathological era of surgery the idea was to destroy microbes or to prevent their growth. It included also methods for the removal of microbes and their products from the surgical field in operative work.

The professional imagination became so thoroughly captivated with a scientific toy in the third era that surgery gained tremendous momentum and velocity. The whole profession got under such headway that it was not inclined to stop and think over the principles of a still newer fourth era in surgery, the physiological era when Metchnikoff and Wright came along and told us about the natural protective forces of the individual; (normal cell protection against invading microorganisms). It was while giving attention to the principles of this gentler fourth era that I made observations which must still be taught and taught by object lessons for a number of years more.

Tuberculous lymph glands of the neck offer excellent opportunity for making a comparison between the third and fourth era methods of treatment. Third era methods call for removal of the infected glands. Third era treatment undervalues the fact that cervical gland infection is always a secondary phenomenon. Fourth era treatment on the other hand is always aimed at the primary focus. It includes minor surgery only. It depends upon calling out the protective forces of the patient, aided locally by forced hyperemia, the x ray, iodoform injection or other chosen resources in connection with treatment aimed at the primary focus.

It is no longer necessary for me to do much more teaching on this particular point because European surgeons are now at work with fourth era methods in these cases. Surgeons in this country will shortly get up to date in the matter.

It seems to me that it would be all wrong for one to retire until the profession in general has taken up the principles of a new era requiring object lesson teaching. To illustrate: When I published a list of one hundred appendicitis cases with a death rate of two per cent. made possible by the application of fourth era principles a man with the standing of Dr. E. C. Savidge wrote a letter to the *Medical Record* stating that such figures were "vainglorious cheats." In his opinion they represented a selection of cases for favorable report in the interest of the surgeon making the report. It meant that cases with serious complications, the ones most requiring the surgeon's help had been refused operation. The publication of such a report to his mind was despicable. (As a matter of fact the cases were unselected consecutive cases reported at face value.)

A surgeon of the standing of Dr. W. W. Keen stated at the Denver meeting of the American Medical Association that no one could get such a low death rate in abdominal surgery even if the patient did not have appendicitis. I do not remember

Copyright, 1924, by A. R. Elliott Publishing Company.

whether it was Dr. Howard Lilienthal or Dr. L. W. Hotchkiss of New York who first began to listen but Dr. Hotchkiss was connected with a hospital where there were many emergency cases with an operative appendicitis death rate of thirty-one per cent. He suddenly changed over to fourth era principles and had a run of seventy-six consecutive appendicitis operations without a single death. It made a difference to fathers, mothers, brothers and children if they went to Dr. Hotchkiss for appendicitis operations or to surgeons who were not having seventy-six cases without a death following operation.

So long as the profession is still confining itself largely to third era principles what right have certain individuals to retire from the teaching of fourth era principles? Antagonism has been considerable in degree. This is not said in a spirit of complaint. In fact I rather believe in that sort of thing because there are so many false notions gaining headway from time to time (some of them were my own) that responsible surgeons who are well grounded in the ways with which they are familiar must be ever antagonistic to new views until they feel assured that the patients under their care are to be benefited in new ways.

PRINCIPLES OF FOURTH ERA SURGERY

In pyosalpinx cases treated by fourth era methods there is no need for removal of infected tubes and ovaries no matter how badly damaged they appear to be. If the tubes are split wide open, fastened to the anterior abdominal wall and drained externally while the patient is being treated with vaccines and with hygroscopic astringents a notable recovery is the rule. New fimbriæ and oviducts with new lumina may appear in cases in which at the time of operation it was difficult to distinguish ovary from Fallopian tube in the ragged bleeding mass which was fastened to the anterior abdominal wall temporarily.

Surgeons trained in the principles of third era surgery should not believe this at all when simply told about it. It is necessary to give repeated object lessons to the younger men on the hospital staffs and to let these younger men become impressed in their own way.

It seems to me that no one has a right to retire from practice when he is in a position to show how women may be brought back to child bearing in cases in which devastating pelvic surgery of the third era is still the rule.

In bladder surgery fourth era principles allow us largely to do away with the carefully and conscientiously devised aseptic apparatus of the third era which imposes great hardship upon the patient. Instead of the irritating bladder drainage tubes, the aseptic bottle under the bed and the irksome position of the patient upon his back, fourth era methods frequently allow the patient to be sitting out of bed shortly after the operation, wearing a small drainage wick and a pad of sphagnum moss in such a comfortable sort of way that he reads his newspaper instead of thinking of eternity. This is one of the things which men trained in third era principles will not believe, in fact should not believe until shown.

When the rubber glove was perfected as a valuable adjunct to surgery relating to the third era it had bad application in abdominal surgery. It interfered with a nice sense of touch required for speedy work through short incisions. The rubber glove made a break in aseptic technic because more bacteria fall into a large wound from the air than are carried into a small wound by well prepared hands. Large incisions and bungling work belonging to the rubber glove led to the present popular mistake of routine examination of various other abdominal organs whenever the surgeon's hand is introduced into the abdominal cavity for some one objective. This adds a violent attack of surgery to the patient's other troubles. Dr. T. L. Bennett once said that the best surgeon is the one who acts all of the while as though he were afraid of waking the patient up. My assistants must be taught to avoid waking the patient up.

According to the principles of the fourth era in surgery one must make such good diagnosis in advance of operation that he does not need to paw vital organs as an alternative to good preoperative diagnosis. Apropos of the pawing point, I once read an excellent description of treatment for postoperative gastric dilatation but wondered where so many cases came from. Sometime later I saw this operator make more than eighty false motions in an abdominal operation after I began to count. Each false motion registered a destructive impulse in the centres of consciousness of that patient. Young men must be taught that "the hand of the learner in surgery is heavy." False motions constitute a heavy blow from the hand.

If one works in abdominal surgery without rubber gloves the results are such that the object lesson is bound to impress observers. A surgeon has no right to retire from practice while younger men need to be shown something that is opposed to the regular teaching of the schools on that point.

THIRD AND FOURTH ERAS OF SURGERY COMPARED

Acute perforations of abdominal viscera introduce excellent opportunity for making comparison between the third and fourth eras of surgery. In cases of typhoid perforation of the bowel and in cases of gastric or duodenal perforation, caused by ulcer, half an hour or more of surgical work is required for third era methods which would remove infectible material and repair the damage done.

Some of the patients in this group are in no condition to bear the effects of an attack of surgery of a half hour's duration, yet they may make first rate response to a fourth era operation which requires not more than one minute of time for its performance. There is always opportunity for the exercise of surgical judgment, but the operator who has only the resources of the second and third eras at hand still needs to be taught what may happen when he applies fourth era methods in desperate cases.

One may ask why the leaders in any profession remain behind the times. It is because of their recognition as leaders. It means that their time is so fully occupied that time limitation interferes with acceptance of new ideas promptly. They are to be honored for their slowness that goes with sureness but is it right for the rest of us to retire and leave the profession to "play safe" in its ruts of ritual and of habit-thought?

Furthermore, in matters of behavior there is always a tendency for a profession to slump into commercialism. Idealists who enter our profession in a spirit of nobility of purpose may became shocked and

confused when they see large incomes running upon the wrong track. Older men are to hold up the hands of these younger men—to give them backbone instead of wishbone. We must remain in the field at a time when for personal joy we would prefer to retire from practice and to expend our coupon years upon useful hobbies.

Treatment of the Patient With Gastric or Duodenal Ulcer*

CLEMENT R. JONES, M.D., F.A.C.P.

Pittsburgh, Pa.

Modern interest in gastric ulcer began following the papers of Gruveilheir published 1829-1835 and since then this subject has been constantly before the profession. There are many phases of the subject as announced, but as internists we are more interested in the etiology, pathology diagnosis and treatment. To be clear in etiology, diagnosis and certain of our rationale is the key to successful treatment.

The contributory or predisposing causes of ulcer of the stomach may be suggested as those which alter metabolism producing interference in circulatory, glandular, nutritional or nerve supply and function of the organ. There are circulatory disturbances due to changes in the thyroid, suprarenal, pituitary, thymus, parathyroid and the gonads. The spleen and possibly other glands may when in a state of infection or abnormal function play a considerable rôle in the etiology of ulcer, as does also systemic infection or bacteriemia due to focal infection of teeth, tonsils, sinuses, appendix, gallbladder, the tubes or ovaries, prostate gland and other parts of the body as the colon infected by ameba or other intestinal parasites, complicated by infection. Syphilis, tuberculosis and cancer are major causes of pathology in ulcer. Occupations which are accompanied by inhalation of poisonous gases, also gases used in time of war and the absorption of poisons by other modes of entrance, are predisposing or direct causes; shock, overwork or other interference with the normal balance between vagus and sympathetic systems and trauma, such as extensive burns, have been followed by gastric and duodenal ulcer.

PATHOLOGY

Ulcer is usually preceded by an erosion which continues until it involves the submucosa and muscularis. Erosions in the fundus, or greater curvature as a rule heal promptly, but, in the lesser curvature, or that part of the stomach called by Aschoff, "the gastric pathway," the alley through which pass foods that are more or less rapidly carried into the duodenum, here single or multiple erosions do not heal promptly, and if the conditions favorable to repair are absent, the deepening erosion becomes an ulcer, and while this unfavorable state lasts and the food is irritating in physical and chemical make-up, the ulcer may continue to widen and deepen into the funnel shaped character so common in this location, the apex directed toward the cardia and the base toward the pylorus with the overhanging cardial margin definitely demonstrable. The preulcerative period during which we have in many patients symptoms of fullness, occasional postprandial pain and eructation of gas and acid, is no doubt one in which one or more erosions are forming and healing. After a while the condition, both constitutional and local, becomes such that the stage of acute, subacute and chronic inflammation follow more or less rapidly, and we are confronted with a patient suffering from well established gastric ulcers.

Any one or a combination of a number of the conditions outlined above may result in the disturbance of metabolism which is necessary to produce the state of lack of resistance which will allow the formation of ulcer.

Cohnheim calls attention to the climacteric ulcer which may be the result of the endocrine readjustment which is taking place at the time of the menopause. There is also the ulcer of chlorosis which occurs during adolescence, the etiology of which has not yet been satisfactorily explained. In 1920 Dr. Smithies gave a classification based on etiology which includes the chlorotic ulcer but not the climacteric ulcer, to which may also be added the tuberculous and under his industrial intoxication we may include poisonous gases of industry and war. It is probably necessary to have sufficient chemical or physical direct trauma to produce the solution of continuity of erosion in the mucosa. When once an ulcer is started it is difficult to heal until the predisposing causes are to some extent under control or relieved. The disputed hypothesis of the degree of gastric acidity and its place in the etiology of ulcer may be disposed of by saying that it probably has a minor part to play in some cases, but it is necessary to have the lack of resistance or constitutional condition producing a disturbance of metabolism, plus local trauma. Hyperacidity has not been shown to be the predisposing cause of ulcer; we have a considerable percentage of ulcer patients who have either subacid secretion or no hydrochloric acid in the gastric secretion. There are many patients showing extreme hyperacidity with no ulcer present. Rough or otherwise irritating food has much to do in preventing healing. Digestion of devitalized stomach tissue undoubtedly occurs, but the state of tissue predisposition is not produced by direct trauma or excess of acid. These may be factors when there is lowered vital resistance, reduced vitality through the nervous system, the circulation or metabolism.

*Read before the American Therapeutic Society, at Toronto, Canada, May, 1924.

DIAGNOSIS

During recent years we have not depended on the vomiting of blood for diagnosis. Up until a few years ago diagnosis of gastric ulcer was seldom made without hematemesis. It was frequently discovered later that the hematemesis was due to another cause than ulcer. The other extreme was reached in Moynihan's work where he relies almost wholly on the anamnesis for the diagnosis of duodenal ulcer. The clinical diagnosis of gastric and duodenal ulcer is difficult and must be confirmed by positive x ray findings or other conclusive evidence. Many cases of ulcer do not give x ray evidence of a positive character. There are many proved cases of ulcer in which surgical and pathological findings make certain the diagnosis, where careful searching x ray studies are made with no evidence of ulcer shown either on the fluoroscopy or radiograms. The history plays a large part in the diagnosis of this disease, but needs the support of physical findings. A history of pain at definite time, before or after meals, relieved by or increased by eating, is a symptom of diagnostic value and probably the most important point in the diagnosis of ulcer. However, there are ulcers without complaint or pain. Relief of epigastric pain by orthoform, five grains in fifteen to twenty minutes, was first mentioned by Dr. Murdock as a diagnostic test for ulcer; a definite point of tenderness in the epigastrium and one opposite the tenth and twelfth dorsal vertebræ on the left side; a positive Einhorn string test of the presence of occult blood in the feces or tarlike stools, also gastric blood, all contribute to make up the picture of gastric or duodenal ulcer, but any of these symptoms may be absent and yet ulcer be found.

Examination of stomach contents is of great assistance in spite of the statements to the contrary made recently by those who see only the acidity as recorded on the chart and do not examine the contents for other evidence of pathology; such as the state of secretion and excretion, regurgitation, motility and retention; infection, fermentation, putrefaction and other findings. These are points of value in determining the state of the patient to be treated, and are properly a part of the diagnosis and at times very helpful in the treatment. Differential diagnosis may be necessary between epigastric hernia, cholecystitis, cholangeitis, appendicitis or gastric symptoms of nephritis or gastric crisis of tabes. (Acute perforation may be confused with pneumonia or another acute inflammatory condition of the abdomen.) Arteriosclerosis, lead poisoning, nephrolithiasis, acute and chronic gastritis, hyperchlorhydria and cancer.

PROGNOSIS

Under careful medical supervision the prognosis is good as to relief from symptoms and healing of the ulcer, but permanent relief depends upon removal of the cause or underlying metabolic or constitutional state. The prognosis is best when the evidence by signs and symptoms of such condition are sufficient to recognize the predisposing cause of the ulcer; be it focal infection of gall bladder or appendix, vagotonia, syphilis or other disturbed states. Such cases are not always plain and may be recognized with difficulty.

The transition of ulcer into cancer has not as yet been proved although pathologists, internists, and surgeons have long sought a solution of the problem. "Does simple benign ulcer of the stomach become malignant with a frequency which should give such a complication a prominent place in prognosis." My conclusion after thorough statistical research announced in a paper read before the American Gastroenterological Association in 1923, is, that it does not.

TREATMENT

The treatment of the patient that has the ulcer and not the ulcer that has the patient is the most important dictum in the management of any case. Each patient is an individual and is a complex problem to understand before undertaking the relief of the ulcer in his stomach or duodenum. Points to be included in an examination on which to base treatment are the various evidences of constitutional inferiority such as habitus enteropticus, cranial and facial asymmetry, visual defects, high arched palate, maxillary and mandibulatory prognathism, irregular denture, long slender bones or disproportionate bony growth, irregular distribution and growth of hair, as unusual eyebrows, pubic hair of opposite sex type, age and character of change of voice and growth of beard in male, age at first menstruation in female, peculiarities of appetite, urinary and sex habits and sweating, cold hands and feet, instability of pulse and temperature, sexual immaturity, inability to nurse a child, sterility, emotional instability, food aversion and allergy.

We must consider an inferiority complex and egotism, overweight or excessive underweight, marked variation from two main types, the tall thin and the short stout, tonsils and adenoid development infection from and obstruction by, the basal metabolic rate indicating the state of the thyroid and other conditions, the evidence of abnormal parathyroid, pituitary and suprarenal states, vagal or sympathetic dysfunction, the vagotonia of Eppinger and Hess, eyestrain as hypertrophic astigmatism, occupational or business nerve strain, mental disturbances due to shock, fear, fright or other causes, infection of the focal variety causing bacteriemia with a secondary infection located in stomach or duodenum and sometimes simultaneous infection of the appendix, biliary tract and stomach or duodenum.

A very clear case, which I have already reported, followed an acute case of tonsillitis with appendix, gallbladder and duodenum all in simultaneous subacute inflammation. A combination of a number of these conditions increases greatly the difficulty of both treatment and diagnosis.

After a complete survey of the patient's condition, along the lines mentioned above, it may then be determined what local measures should be taken to promote the healing process.

In planning treatment for an individual who has been found to have as a manifestation of his ill health an ulcer in stomach or duodenum, we are always called upon to suggest one or other of two treatments, ambulatory or complete rest in bed. Any modification of a complete rest in bed treatment should be classed as ambulatory. Local conditions in the stomach may be improved by diet suitable to

the zymotic state, the inflamed condition of the organ, and the hypersensitiveness of the patient. We not infrequently find anaphylaxis reaction to milk and eggs, which are the basis of certain dietetic treatments of gastric ulcer, and when no rennin is present in the stomach we have found that many patients are more satisfactorily treated with buttermilk as part of the diet. Duodenal feeding with a tube by the Einhorn method using the Murphy drip apparatus has proven very useful in some cases, where all food was distressing to the irritated stomach and in others where food of any kind seemed to interfere with the healing process. If a luetic ulcer is present and antiluetic treatment is used, little else is necessary, but a diet which will not irritate either by its chemical or physical properties will increase the rapidity of the cure. Unfortunately we are not able to meet other causes as we are lues. We find that ulcer of the stomach due to one of the other more or less indefinite states may require more attention to local treatment and general health measures.

We must deal in many instances with food hypersensitiveness or protein allergies, as well as the chemical and physical state of the food and its action on the stomach in an ulcerated state. We must consider the effort required on the part of the stomach to digest the food and the stimulating effect which such food may have on acid and enzyme secretion and the motility of the organ. (Efforts to promote the healing process in ulcer of the stomach and duodenum are based on removal of the conditions which started a lowered resistance allowing trauma plus local infection, fermentation or putrefaction of retained food and acid digestion, to start and maintain an ulcer.)

The food when rough, sour and indigestible, or where anaphylaxis to it exists, continues a condition unfavorable to the process of repair. The constant peristaltic movement of the ulcerated stomach wall surrounding a meal mass of rough, sour and highly seasoned food is not an ideal gastric exercise and of course prevents any attempt at natural unaided healing. If there be a mild or only slight metabolic disturbance or lowering of tissue resistance, a correction of dietary indiscretion and shaping a food program to meet the zymotic and physical pathology of digestion is at times all that is required to cause healing of the ulcer. If the primary impairment of resistance is great we may expect frequent recurrence, and local conditions must be ideal as to rest and diet to bring about a satisfactory result; recurrence will likely follow unusual stress on the stomach by lifting, jolting or dietary indiscretions.

If the primary etiology has been removed we may expect a return to normal on the part of the stomach and food will have little or no unfavorable influence on the healed stomach. These patients will say, "I can eat anything without causing trouble." As a rule a modified milk as food is acceptable, finely divided, well cooked cereals and soluble albumens are well borne by the stomach. Rest in bed in cases complicated by ptosis is almost always necessary. The ambulatory treatment is more frequently successful in men than in women for the reason that ptosis is more common in women. When marked ptosis is present in either male or female a period of three to six weeks' rest in bed with the foot of the bed elevated at least six inches aids materially in arresting the symptoms and promotes the healing process. It has been my experience that the shorter rest periods in such cases are usually not successful. The length of time during which the patient should take liquid, soft or semisolid foods must be determined by the condition in each separate case. Where there is a definite tender spot in the epigastrium liquids should be given until the tenderness has disappeared. It is absolutely impossible to accept any scheme to follow any rule for certain foods for one week, other foods for the next week increasing for the third and fourth week. One patient may be so constituted as to do well on milk, modified or plain and another may do well on gruels, rice water or other liquid or semisolid food and consequently such variations as fit the constitutional peculiarities of the patient and his ailment are points to be decided in the treatment of each person.

COMPLICATIONS

Pain, pylorospasm and hyperperistalsis may be relieved greatly by application of heat and moisture to the epigastrium. The flaxseed poultice of former times may be improved on very much by the use of an electric hot pad. Care not to blister the skin is necessary. In severe pain orthoform in five grain doses every sixth hour as a rule gives satisfactory relief. Unless vomiting is due to obstruction the application of heat as above with the addition of tincture of belladonna given to the point of dryness of the throat or dilated pupils will usually be an effective remedy.

Perforation is a complication to be anticipated by instructing the patient of the possibility of a sudden severe pain with shock and the importance of his physician and surgeon being notified at once. To neglect this is the one great danger, failure to recognize the perforation is almost certain to result in the death of the patient. The earlier the abdomen is opened and the perforation closed the greater is the patient's chance of recovery. Hemorrhage due to erosion of vessels in the gastric and duodenal ulcer or exulceratio simplex of Dieulafoy may be successfully managed in a large percentage of patients, by the following treatment:

First allay the fear usually associated with it, inhibit all unnecessary movements on the part of the patient, have as few attendants as consistent care will permit, allow no visitors, apply ice to epigastrium, give morphine hypodermically. Internally epinephrinized gelatine in doses of a tablespoonful every three hours, gelatine to be of the consistency of syrup and contain thirty drops of one in a thousand solution of epinephrin to each tablespoonful to be added at the time of administration. No other food or medicine to be given by mouth until all evidence of hemorrhage has disappeared and epinephrinized gelatine to be continued until occult blood is no longer present in the stool.

Surgical procedures are a necessary part of the treatment of certain complications of ulcer, but have no place in the treatment of uncomplicated or simple ulcer. Surgery is available for the relief of stenosis by one of the approved operations, pyloro-

plasty or gastroenterostomy being most satisfactory; the latter, when the stenosis is complete and the former, when partial stenosis permits of that operation. Surgical treatment for the relief of hemorrhage of the stomach has been unsatisfactory in most cases, but operation in the interval between hemorrhages for the purpose of excising the ulcer or cauterizing and infolding it, has given more favorable results. Perforation as stated above requires that surgery be resorted to at once if the patient's life is to be saved. We should keep in mind that with surgical as well as medical management of ulcer and its complications changes in local conditions do not remove the primary etiology.

Treatment of the subject to keep him well, or to prevent a recurrence in spring or fall, or at whatever time his accustomed attack may be due, is a task to which most careful attention must be given and in which the physician must have the hearty cooperation of his patient if he is to be successful in keeping him well. If the etiology has been discovered in a focal infection or other removable cause, and it has been removed, then the task is not so difficult, but if the ulcer is of idiopathic origin, too much attention cannot be given to details even of a minor character as to habit of living and diet. In neurasthenic individuals with a tendency to introspection, it is necessary to avoid such directions as will favor a continuance of the fault. This is sometimes difficult to do and yet secure adherence to dietary and other regulations. It can be done better by positive orders as to what must be done than by restriction or "forbidding" orders.

The medical or surgical treatment by rest cure or operation are a preliminary measure to the care and medical management of the patient, diet, exercise, occupation and habits, in fact all the activities of mind and body should be so directed as to maintain a state of resistance above the predisposing level necessary to permit a recurrence.

The Treatment of Lupus Erythematosus by Filtered X Ray to the Glandbearing Regions of the Body

WILLIAM H. GOECKERMAN, M.D.
Rochester, Minnesota,
Section on Dermatology and Syphilology, Mayo Clinic

It is evident to the experienced dermatologist that purely local treatment of almost any type of lupus erythematosus is unsatisfactory. Too often an indolent patch will improve, only to show an extending border later. Or new lesions will appear when the old patches are seemingly under control. Efforts to influence the constitutional background, therefore, seem logical. In the absence of any exact knowledge of the etiology of lupus erythematosus, such efforts must remain empirical. Any measure that affords help in the management of so resistant a disease is welcome, however.

In 1923 I reported a case (1) treated with filtered x ray to the glandbearing areas of the body in a manner similar to that commonly used in Hodgkin's and other lymphogenic diseases. The response was immediate and striking after all other local and constitutional treatment had failed. My experience in this case induced me to continue this form of treatment in sixteen additional cases.

REPORT OF CASES

Case I.—(A373335). A man, aged thirty-three years, was seen at the Mayo Clinic for the first time September 27, 1921. His face was extensively and symmetrically affected, and there were a number of patches in the upper sternal region. He had been treated elsewhere with local measures, such as carbon dioxide snow, the x ray, and ointments. Examination revealed marked activity of the lesions, also atrophy and telangiectasia. Tuberculosis was not demonstrable. No pyogenic foci were found except questionable tonsils, which were removed. The patient was given quinine internally, and a calamine lotion with two per cent. iodine in benzol, locally. On his return in March, 1922, the eruption had not changed appreciably, and soon afterward the first of a series of filtered x ray treatments was administered to the glandbearing areas. One month later decided improvement was noted. At this time a series of x ray treatments of a similar type was repeated. In August, 1922, the lesions on the chest were entirely involuted and the facial lesions had diminished greatly. In December of the same year a fourth series of the x ray treatments was given. In September, 1923, a few very small erythematous patches remained; these involuted promptly under local treatment with radium. The result, thus far, has been very satisfactory.

Case II.—(A390080). A woman, aged thirty-seven years, in whom there developed lesions of the rather indolent type. She had achylia gastrica, and probably, chronic cholecystitis. Five infected teeth were extracted, and one series of filtered x ray treatments was administered. The outcome in this case is not known since contact with the patient was lost.

Case III.—(A393641). A man, aged forty-four years, had lesions of the disseminate type, and obscure abdominal complaints. He had been given the conventional treatment, including removal of tangible pyogenic foci, without appreciable response. A series of x ray treatments to the glands was given. The patient has not been heard from since.

Case IV.—(A403905). A woman, aged thirty-three years, had an acute lesion resembling closely the erythema perstans of Kaposi. She was persist-

ently febrile when admitted to the hospital September 6, 1922. The temperature later became normal. All tangible pyogenic foci were removed. The patient improved considerably with rest in bed and other measures. From October 10th to October 13th a series of filtered x ray treatments was given. The patient made a complete clinical recovery, and was dismissed from observation in good condition October 24. A certain amount of the beneficial effect must be credited to the x ray, but some of it should be attributed to rest in bed and hygienic measures.

Case V.—(A413651). A girl, aged nineteen years, examined December 28, 1922, was found to be very toxic, with erythema perstans, and periodically marked defluvium capillorum. Pyrexia subsided with rest. The infected tonsils were removed. X ray of the chest disclosed a definite old tuberculous lesion which clinically was probably not active. The first series of x rays was given from January 18 to 20, 1923. The patient was seen by the entire dermatological staff of the Clinic February 2nd, and it was agreed that a remarkable improvement had occurred. April 2nd she returned to the Clinic, because of a relapse, but she had gained ten pounds in weight. Another series of x ray treatments was given with considerable benefit. She gradually failed, however, and died September 28th.

The patient in this case had been unable to carry out the treatments as advised, but it is doubtful if any treatment would have changed the outcome.

Case VI.—(A221958). A girl, aged nineteen years, presented the discoid type of lesion, which had resisted all efforts at treatment, even destruction by carbon dioxide snow. Active borders reappeared persistently. She was given a series of x ray treatments in September, 1922, with sufficient benefit so that she requested a second series. The x rays did not induce total involution of the patches, but the lesions healed completely in a short time, under the local application of radium, and have shown no activity since.

Case VII.—(A412484). A man, aged thirty-one years, had noted numerous patches on the face; most of them were of the acute type, but some were definitely discoid. His hair lacked luster; he had no endurance and complained of night sweats. No tuberculosis could be demonstrated, and no pyogenic foci were found. Under one series of x ray treatments all lesions gradually disappeared while the patient was ambulant. His vigor returned to normal, enabling him to take a position which entailed considerable physical activity. The luster of the hair was strikingly improved. The remainder of the treatment consisted of indifferent local applications and general hygienic measures.

Case VIII.—(A415268). A woman, aged thirty-three years, had the definite discoid chronic type of eruption, with multiple lesions on the face. A series of x ray treatments was given without response. Other measures, including those of a local destructive character, were also unsatisfactory.

Case IX.—(A416049). A woman, aged forty-six years, had lesions of the disseminate type, involving all of the face, neck and a greater part of the forearms. One series of x ray treatments, soon after the patient was examined, produced a decided improvement of the lesions, and a gain in general health. X ray examination of the chest revealed a thickened pleura at the left base and calcified mediastinal glands on the left side. No pyogenic foci were found. The patient was at the Clinic from January 23rd to February 5, 1923. When she left, the eruption had practically disappeared. Local applications were not used at any time.

Case X.—(A421900). A woman, aged thirty-two years, had the disseminate type of lesion with little constitutional intoxication. No demonstrable tuberculosis was noted. Four periapical infections were found, and the tonsils suggested infection. One series of x ray treatments was given with no striking response. Various other measures were used, but the final result was not striking. The value of the x ray treatments could not be estimated in this case.

Case XI.—(A425222). A woman, aged forty-three years, was examined May 10, 1923. She had a butterfly shaped patch of the discoid type over her nose, and disseminate lesions on the scalp, face, neck, forearms, and hands. Tuberculosis could not be demonstrated, and pyogenic foci were not found. A series of x ray treatments was given from May 14th to May 18th. May 29th, a decided improvement was noted. June 8th, the disseminate lesions had practically involuted and the discoid patch had appreciably diminished. From October 22nd to 26th, another series of x ray treatments was given; following this, there was no evidence of active lesions. This patient had also received quinine, and various mild local applications. The very prompt response in so extensive an involvement, as seen in this case, favors the belief that the x ray was responsible for the result. The patient was again seen in June, 1924; the lesions were completely involuted.

Case XII. —(A431237). A woman, aged forty-five years, had rather extensive lesions of the face, of the chronic discoid type. Three series of x ray treatments and mild astringent local applications diminished the lesions materially, but the patient's general condition remained poor except for a slight gain in weight. The constitutional complaints could probably be explained by a bronchiectatic cavity from which the patient expectorated spirilla. The results were no better than might have been obtained by rest and tonic measures.

Case XIII.—(A433598). A woman, aged forty-years, had lesions of the disseminate type on the forehead, face, and hands. She complained of lack of endurance, but otherwise felt well. An old tuberculous focus in the right lung was revealed by the x ray. No definite pyogenic foci were found. Three series of x ray treatments afforded marked improvement. Definite benefit was noted after the first series, given in July, 1923.

Case XIV.—(A442612). A woman, aged thirty-nine years, had rather extensive involvement of the face from an active discoid lesion. An old tuberculous lesion in the left lung was revealed by the x ray. Six infected teeth were removed. After one series of x ray treatments in October, 1923, the lesion improved so much that her friends at home "hardly knew her." She was given a second series of x ray treatments in December, and when she left

the Clinic there were no active lesions. This patient had taken small doses of quinin for about a month. The local treatment had been pursued for a short period with an ointment containing ichthyol, resorcin, and precipitated sulphur. The Kromayer lamp with pressure to the lesions was also employed, and must be credited with at least part of the satisfactory result.

Case XV.—(A424077). A woman, aged fifty years, had rather extensive discoid lesions on the face, with active borders. Old tuberculous foci in both upper lobes were revealed by x ray examination. The tonsils were in fairly good condition, and the teeth showed no periapical infection. The usual measures of treatment were employed, and an ointment containing five per cent. ichthyol, five per cent. sulphur precipitate, and five per cent, resorcin, a solution of two per cent. iodine in benzol, and quinine in small doses was continued at home. The patient returned to the Clinic about one year later. No striking benefit was noted. She was then given two series of x ray treatments and the lesions were exposed to the Kromayer lamp with very satisfactory results. The patient is still under treatment.

Case XVI.—(A464665). A man, aged thirty-seven years, had a chronic patch on the nose, and many of the disseminate type on the face, neck, arms, and hands. Tuberculosis was not demonstrable, nor could any pyogenic foci be found. The patient received a series of x ray treatments in May, 1924, and another in June. The response has been very good, and treatment is being continued.

Technic of X Ray Treatment Employed

The irradiation of the principal gland bearing areas of the body was carried out in a manner similar to that used in the lymphogenic disorders, notably Hodgkin's disease. The exact dose varied somewhat, but a good example of the various factors employed in most of our cases follows:

1. For cervical, axillary, and inguinal regions

Kilovolts	Distance	Milliamperes	Filtration	Time
135	12 inches	5	4 mm. aluminum	10 minutes

2. For chest and abdomen anteriorly and posteriorly

Kilovolts	Distance	Milliamperes	Filtration	Time
135	12 inches	5	6 mm. aluminum	10 minutes

These treatments were usually repeated every six to eight weeks. The lesions were not directly exposed to the x rays.

Discussion

The case records show that strict experimental conditions were not maintained. This was impossible for practical reasons. In a number of cases a determined effort was made to restrict therapeutic measures to the x ray. Lupus erythematosus sometimes improves with a slight change in hygiene, and the mildest astringent applications may have a beneficial effect. I feel satisfied, however, that the results in this series of cases are better than have been obtained by any therapeutic measure with which I was previously familiar. When x ray treatment proves beneficial, the results are very apparent in a few days, sometimes within twenty-four hours. This treatment is not intended to replace older internal remedies, nor should it be substituted for local applications that have been tried and found satisfactory. The treatment will, in many instances, produce a decided improvement in the general physical condition and inactivation of the cutaneous lesions by its constitutional effect, thus providing a favorable setting for local remedies.

In Cases I, IV, V, VI, VIII, X, XI, XIII, XIV, XV, and XVI, the results were most satisfactory. In Cases II, III, and X, the treatment did not have a reasonable trial, chiefly because of lack of cooperation on the part of the patient. In Cases VIII and XII, it proved of no benefit; neither did any other form of treatment.

The rationale of this method was originally based on the assumption that the pathologic focus of lupus erythematosus lies primarily in the glandular system. The literature is filled with reports of tuberculous adenopathy associated with lupus erythematosus. Gennerich (2) reported a case of extensive non-tuberculous glandular disease associated with the eruption. My own experience in several cases taught me that a scrutinizing clinical investigation for tuberculosis may be entirely negative, yet at necropsy large masses of tuberculous, mediastinal, abdominal or pelvic glands may be found. Such facts and the wellknown observation that lymphogenic diseases and tuberculous glands respond favorably to the treatment by x ray induced me to give this method of treatment a trial in lupus erythematosus.

The beneficial effect seems to be rather in the nature of a foreign protein shock than a direct destructive or inhibitory action on the glands exposed, and is apparently in direct proportion to the x ray nausea engendered in the patient. Improvement is often so rapid that gradual changes in the glands can hardly explain it. Studies of the blood may help to throw further light on the action of the x ray in these cases. Extensive studies of this character were not made in the Mayo Clinic series. It was noted, however, that the leucopenia so frequently associated with the more acute type of lupus erythematosus was improved by the x ray treatment, but this may simply have been the result of the general improvement in the patient. If the effect is in the nature of a foreign protein shock, it probably differs from that seen after the parenteral injection of such substances as killed typhoid bacilli or peptones. At least I have never been able to obtain any results comparable to those following this method of x ray treatment. The removal of pyogenic foci will not explain the improvement. Because of the frequently severe reactions following dental extractions when the disease showed a tendency to disseminate, x ray treatments were given to improve the general physical condition with the intention of removing the pyogenic foci later, but decided improvement often occurred before the teeth were interfered with.

Filtered x ray treatment of this type seems to be most valuable in the fairly acute case that is not so toxic as to have caused severe injury to a vital organ. A patient, subject to severe attacks of hyperpyrexia, and one who has much albumen in the urine and marked myocardial injury, will often be strikingly benefited, only to succumb to the disease in the usual manner. In the chronic discoid type with an inflamed progressive border, inactivation can be

achieved, permitting subsequent efficient local treatment of the patch. Thus far, I have been able to give a satisfactory number of treatments in only one case (Case I); the results were very satisfactory. My aim is to give at least five or six series of exposures. It is, therefore, impossible to say at present whether relapses will be as frequent as under other methods of treatment. It is not likely that the results will be absolutely permanent, since we probably cannot as yet reach the cause of the disease. Nevertheless, the addition of this to other types of treatment often proves satisfactory.

Aortitis

GEORGE S. BEL, M.D.,
New Orleans, La.

Physicians who have had broad experience in the management of cardiovascular diseases are forced to the conclusion that there is not as comprehensive a knowledge of the diagnosis and management of aortitis among the general practitioners as may be desirable. This latter may be attributable primarily to the infrequent recognition of this morbid condition by the family physician whose opportunities for clinical study and observation are, as a rule, somewhat limited. Bearing these facts in mind, this paper is not written for the skilled cardiologist, but for the possible benefit of the general practitioner whose duties are manifold and opportunities generally limited.

An aortitis may be satisfactorily defined as an inflammatory process, either acute or chronic, involving either in whole or in part the main trunk of the arterial system, the aorta. With rare exceptions, aortitis is the direct result of action of microorganisms or their toxins, some of which may show selective action upon vascular tissue. Occasionally inflammatory processes involving the aortic adventitia are met with as true secondary processes—as some acute or chronic disease implicating the external coat of this great vessel by contiguity of surfaces as may be seen during the course of pericarditis, mediastinal abscess, ulceration of the trachea or esophagus. With this type of disease, we naturally are not interested in this discussion.

ACUTE AORTITIS

My personal observation has led me to believe that acute inflammation of the aorta is comparatively common, but frequently not suspected—in some cases unrecognized because of its occurrence in the course of acute infections, and being regarded as simply a part of the symptom complex of the disease. Sometimes even at necropsy we are too prone to accept the naked eye appearance of the aorta as conclusive, instead of making a careful microscopical study with a view of determining histological changes occurring in one or more coats of the vessel. An acute inflammatory process affecting a part or all of the aorta and due to the direct action of microorganisms or their toxins may occur during the course of any one of the acute infectious diseases, especially so in rheumatic fever and the exanthems. Typhoid fever, influenza, septicemias are frequent etiological factors. Often, an acute aortic involvement is noted in cases of acute endocardial disease with or without valvular vegetations, and is here to be regarded as a spread by continuity of surfaces of the morbid process. Syphilis is a common, in fact, possibly the chief cause of the production of acute aortic disease.

Considering the pathological anatomy of acute aortitis, briefly, we find that in some acute infectious diseases such as meningitis, scarlet fever, rheumatic fever, and other conditions there is an inflammatory process with its special lesion in and under the endothelium, in contradistinction to the lesion of early aortic luetic infection which begins primarily around and within the vasa vasorum. I will consider these varying anatomicopathological conditions more fully under the discussion of chronic aortitis.

SYMPTOMATOLOGY

The symptoms of acute aortitis may be overlooked, which fact is readily understandable considering its frequency of occurrence in the course of other diseases by which its clinical picture may be completely overshadowed as has been previously indicated. Again its onset may be exceedingly mild in character, producing very few symptoms, and these of short duration, so much so that unless the physician is on the alert and suspecting aortitis, its presence may not be determined. Moderate elevation of temperature usually accompanies the attack, but again one must remember that temperature rise may be due to the primary infection, and not be a manifestation of aortic involvement. There is almost invariably some pain and tightness in the chest. The pain varies from a sense of soreness and feeling of tightness beneath the upper part of the sternum, to a sharp, stabbing, agonizing pain assuming the character of true angina pectoris, and, at times, radiating to the shoulders and down the arms of either side. Leger and Stewart have described a burning sensation over the arch of the aorta, and this I have noticed in one of my cases of malignant scarlet fever; the patient constantly complained of a burning sensation over the upper part of the chest and back. Autopsy revealed a marked endocarditis, myocarditis and aortitis. Dyspnea may be paroxysmal, and frequently comes on slight exertion. Cough and disturbances of the gastrointestinal tract are observed in some cases.

On physical examination, inspection may reveal undue throbbing of the carotid arteries, and throbbing in the episternal notch. The subclavian pulsations may be seen above the clavicles. By placing the index finger in the episternal notch, one can feel a transmitted impulse due to the increase in the amplitude of the aortic pulsation. This sign, of great diagnostic importance in both the acute and chronic types of aortitis, is never detected in a healthy individual except if extremely emaciated. There may be dullness over the manubrium and to the right and left of the first and second interspaces. A loud aortic second sound of a peculiar bell like quality is characteristic on auscultation. In some cases the aortic valves are implicated and systolic and diastolic murmurs become audible. There may also be a systolic murmur from dilatation of the aorta, the aortic valves being healthy.

A routine fluoroscopic examination of the thorax by a trained, experienced röntgenologist is of value in suspected aortic involvement. Careful observation will reveal an increase of the density of the aortic shadow associated with sclerosis, alterations in the amplitude of aortic pulsation, localized or generalized aortic dilatations, or expansile pulsations.

In recapitulation, it may be said that the recognition of acute aortitis depends on the presence of some acute infectious process; the suspicion of the condition by the attending physician; the character and location of the pain; the physical signs indicating an aortic affection; enlargement of the aortic shadow as visualized by the x rays; additionally, in the syphilitic type, a careful history and other evidences of the disease, together with a positive Wassermann reaction when performed by a trained serologist, are of the utmost diagnostic importance.

The prognosis depends upon the virulence of the etiological factor and the resisting powers of the host. Complications, frequently resulting in myocardial changes, coronary arterial involvement, permanent injury to aortic orifice and weakening of arterial wall as to cause dilatation, aneurysm or even rupture are all possible factors to be considered during the course of an acute aortitis. In the syphilitic form, the prognosis depends essentially upon the early recognition of the disease, and the promptness and adequacy of administration of specific therapeusis.

TREATMENT

Treatment should be instituted with a view of overcoming the etiological factor wherever possible. Absolute rest is imperative. The strength of the patient must be sustained by highly nourishing and easily digested food. Ice bag over the sternum is beneficial especially for the relief of pain. Pain if severe is relieved by opiates and if truly anginal in character the nitrites are indicated. If there is much nervous system disturbance, the bromides of sodium or potassium are beneficial. If there is a tendency to cardiac failure, the heart must be watched and cardiac tonics administered, the tincture of digitalis being especially useful in my experience. In syphilitic aortitis, it is of the utmost importance to administer antisyphilitic agents for their full therapeutic effects. Return to active life following an acute aortitis of any type must be made with great caution, and particular attention paid to the occurrence of subsequent substernal pain.

Chronic aortitis may be the result of an acute aortitis which produced permanent dilatation; but the two most frequent resultant pathological conditions designated as chronic aortitis are—depending upon etiology—the ordinary arteriosclerosis and the diffuse syphilitic disease of the aorta. I will dwell more particularly on syphilitic disease of the vessel because its lesions are of deepest significance especially on account of their intimate relation to aneurysm production.

SYPHILITIC AORTITIS

Syphilis has been recognized as a factor in the cause of aneurysm long before the treponemata were demonstrated in the walls of the sac. Today, due to the monumental contributions of Reuta, Benda, Wright, Warthin, Longcope, and others, no one doubts that syphilis is the paramount cause—if not the sole cause—of aortic aneurysm. In syphilitic disease of the aorta, as I previously indicated, the early lesion is now recognized as one primarily of the vasa vasorum supplying the media, and resulting aneurysm occurs after degeneration has taken place in that part of the media supplied by the early attacked vasa vasorum. Here, it may be of interest to call attention to why aneurysms are so prone to result from syphilitic aortitis and not from other varieties of aortic diseases.

Any of the pathogenic organisms or their toxins may give rise to aortitis, but, with the exception of Treponema pallidum, such aortic involvements are primarily of the inner lining of the vessel, the intima, and consist of a primary proliferation of the endothelial cells of the inner coat with only a moderate—if any—amount of involvement of the media or middle coat, never sufficient to give rise to weakening and potential aneurysm formation. Anatomically, this is easily understood, the aorta has two layers of muscle, one an inner circular layer which is thin, and the other an outer longitudinal layer which is thick and constitutes the main support of the vessel. The inner muscular layer is nourished largely by osmosis from the blood current, while the outer muscular coat is nourished by the vasa vasorum.

In aortitis the result of ordinary bacteria or their toxins affecting the intima and causing proliferation, a certain amount of degeneration of the inner muscular coat will result when the proliferated intima reaches a thickness which will not permit of osmosis. This degeneration, however, does not affect the big outer muscle layer because its nourishment is not supplied through osmosis from the aortic blood current. The ultimate result, therefore, of an aortitis due to causes other than the treponemata is the ordinary diffused lesions involving the intima and inner coat of the media and commonly termed arteriosclerosis. The whole vessel may be involved in such a process and will present, to the naked eye, lesions that are soft, firm or calcareous in character, but never are aneurysms formed. On the other hand, aortitis due to treponemata frequently results in aneurysm because the reactionary process is not primarily of the intima. It begins as a perivascular infiltration about the vasa vasorum, which vessels are

the sole means of nourishment to the important outer muscular coat of the vessel. This perivascular infiltration leads in time to an occlusion of the vessels, and this ultimately results in depriving the great outer muscular coat of its nutrition, which can only eventuate in a degeneration, and such a degenerative process destroying as it does the great support of the aorta at the attacked point, results in a bulging or aneurysmal dilatation. The subsequent sacculation of the aorta at such a gummatoidal area may vary from a slight depression to a well formed large sac. At any rate, it increases in size, slowly but surely, unless the underlying cause, viz, the treponemata are destroyed.

The clinical picture and symptoms, to which this paper must naturally have special reference, as set forth here, are those I commonly encountered among my own cases. The symptomatology which attracts attention is especially pain, dyspnea, palpitation and tachycardia. Pain and dyspnea are distinctive symptoms. Pain especially is an important symptom because it is so typical of syphilitic aortitis. It is frequently the first symptom of which the patient complains and one which calls to his attention the need of medical aid. Early in the disease there may be only a sense of constriction and oppression or weight in the chest with some uneasiness along with slight palpitation as well as some dyspnea. The pain varies from a sense of soreness or tenderness beneath the sternum, to a sharp, stabbing along the upper part of the chest reflected to the right shoulder, to the neck, left shoulder or even down the arm. The pain may be constant or intermittent, at first mild, then increasing in severity and frequency, and seemingly increased by exercise. Sometimes the pain is typical of angina accompanied by a peculiar sensation described by many patients "as if the heart were going to stop" as well as by a consciousness of the near presence of death. Dyspnea is an early symptom generally produced on slight exertion but of such mild character as to be little noticed at first. Three of my patients always complained of their inability to walk in cold air without causing dyspnea. In some cases, the shortness of breath progresses, especially if aortic insufficiency is present. In other cases the shortness of breath is paroxysmal, lasting from five to fifteen minutes and leaving the patient exhausted for some time afterwards. Some of these attacks resemble socalled cardiac asthma although there is no decompensation. Such attacks occur with or without aortic insufficiency.

Palpitation and tachycardia are symptoms that usually occur early. When aneurysm is present, the special symptoms and signs depending upon the location and size of the tumor make their appearance. The most important and most constant single diagnostic aid is a positive Wassermann reaction. Next, in my experience, is the determination of the condition of the aorta itself as visualized by the x ray, especially the fluoroscope.

Physical findings in the early stages of syphilitic aortitis, that is, before the aorta has undergone much pathological changes, are practically negative. Later in the disease when the aorta becomes degenerated, the wall weakens and some dilatation occurs which, on inspection, may be noted by abnormal pulsations in the subclavian and carotid arteries, and also by pulsation in the episternal notch. When there is a marked condition existing, one may detect a heave beneath the manubrium or a pulsation in the first and second interspaces, usually to the right of the sternum, but occasionally, as I have seen, to the left. By placing the index finger in the episternal notch, a pulsation is frequently detected and as previously pointed out, constitutes an important diagnostic sign. Percussion gives a slight dulness over the upper part of the sternum and to the right of the manubrium in the first and second interspaces, depending naturally upon the amount of dilatation present. The aortic second sound is sharp, ringing bell like in quality. Frequently there is a systolic murmur at the aortic area. Aortic insufficiency when present is accompanied by its usual physical signs.

Prognosis depends upon the early recognition of the disease, and the promptness with which specific treatment is administered according to the modern accepted methods. If specific treatment is instituted in time, it will undoubtedly stay the progress of the pathological process and avert the development of many aneurysms. Antisyphilitic treatment must be vigorously instituted and continued over long periods of time in order to be efficacious. Salvarsan or neosalvarsan in full doses every seven to ten days for six doses is beneficial, but mercury is by far the most valuable remedy and should be administered by needle or inunction for courses of twenty-eight doses. Iodide of potassium in increasing quantity should be given along with the above treatment. The Wassermann test should be made before and after each course of treatment. It constitutes a valuable aid in the management of therapeusis, especially when positive. It should be borne in mind, however, that a negative Wassermann reaction does not indicate a cure, and should not be construed as indicative of sufficient medication. Such a course as outlined above should be repeated after rest intervals of a few weeks at a time, until disappearance of clinical symptoms, physical signs (in some cases) and persistently negative Wassermann reaction. In my experience, a plan of treatment as outlined above unless followed over a period of years will not prove permanently beneficial. For the relief of pain, nitroglycerin, one one hundredth grain by needle, and if the paroxysms are severe, hypodermics of one quarter grain morphine sulphate are indicated.

SUMMARY

Aortitis is of fairly common occurrence during the course of various acute, infectious diseases.

Syphilis is possibly the principal cause of aortic inflammatory processes.

The diagnosis of aortitis depends upon the correlation of physical signs, x ray, and clinicopathological laboratory examinations.

The prognosis in aortitis depends especially upon the nature of the infectious agent. In the luetic type, it is especially related to early recognition.

Treatment is symptomatic and supportive except in the luetic type, where vigorous antisyphilitic medication is indicated.

Treatment of Pneumonia

GEORGE L. WALDBOTT, M.D.
Detroit, Michigan

The famous clinician, Strumpel, used to say, "Pneumonia usually heals by itself, without any therapy, occasionally in spite of therapy." It might be wrong to allow this quotation to make one an advocate of therapeutic nihilism when facing such a disastrous disease as pneumonia. But there are two conclusions we can draw from this sentence of Strumpel. First, we must be skeptical in interpreting any results of our treatment, and second, we should realize that we are likely to do harm to the patient by our treatment.

It will become evident throughout this paper why the problem of treating pneumonia patients is such a difficult one, and why we sometimes injure instead of improve the patient's condition by therapeutic measures. In an experience with about one hundred cases, which were closely observed in German hospitals and in this country, many different and conflicting ways of treating this disease were demonstrated to me. For instance, one well known clinician used to insist on not giving morphine to a pneumonia patient; while another, equally distinguished, recommended morphine every four hours. Some doctors are using as routine treatment stimulants, as caffeine, and others forcing of fluids to four thousand c. c. a day. Contrary to this opinion, there are doctors who believe in restricting the amount of fluids and in giving caffeine only in emergency.

It is the aim of this paper to emphasize the fact that our first problem is to get rid of any routine treatment. It will be shown that the special condition presented by each patient requires careful individualization. Even the treatment of a single patient has to be varied from hour to hour, according to any changes observed in his condition.

Although my main subject is lobar pneumonia, it will be evident that most of my remarks cover also bronchopneumonia.

When we are about to treat a pneumonia patient, we have to ask ourselves three questions: first, is the patient's life in immediate danger which has to be militated against by therapeutic means? Provided this is not the case we have to inquire, secondly, what can be done to fight the cause of the disease, the pneumococcus, and thirdly, how can we relieve the patient's symptoms? In other words, is the indication for treatment a vital, absolute one, or is it only relative, either etiological or symptomatic? Such a differentiation is necessary since in most cases it is pernicious to continue symptomatic treatment if vital treatment is required, and it is often disadvantageous to continue vital treatment where symptomatic treatment is indicated. For many years in surgery and obstetrics the differentiation of absolute and relative indication has been emphasized. In internal medicine I failed to find any reference in literature to this effectual help in determining therapeutic proceedings. This difference between absolute and relative indication is of the greatest importance, especially in pneumonia.

VITAL TREATMENT

What is the absolute indication? What is the cause of the immediate danger for the patient's life? We all know there are chiefly two conditions responsible for death in pneumonia—cardiovascular failure and anoxemia, deficiency of oxygen in the blood.

CARDIOVASCULAR FAILURE

The toxins of the pneumococcus act on the cardiovascular centre and so cause paralysis of certain capillary provinces, especially in the splanchnic area. This brings about a disproportion in the distribution of blood, clinically seen as the picture of collapse. Much less frequently we see myocardial insufficiency itself, which usually is caused by the great overwork of the heart in consequence of the engorged lungs, or by direct action of the toxins on the myocardium. Seldom are there true pneumococci metastases found in the heart. In acute failure of the circulation, when everything depends on rapidity of therapeutic action, it is useless to start the customary digitalis treatment by mouth. In this event digitalis drugs are effective only if given intravenously, as strophanthin or some glycoside preparations such as digifolin, digalen, verodigen, and others. It must always be kept in mind that any other digitalis medication does not act before the drug has been anchored in the heart muscles and a certain concentration has been reached. It usually requires from one to three days, if given by mouth, and even by the subcutaneous method it takes hours before the therapeutic threshold in the heart is reached.

We know that the most powerful digitalis drug, the most rapid in action, is strophanthin. Thus it is the drug for emergency, but its use in extreme weakness must be guarded. Numerous cases of death following the administration of strophanthin are reported. After reviewing the literature on strophanthin, Rahn (1) advocates that it should not be given if any other digitalis medication was previously administered, if there is evidence of bigeminal pulse or any other irregularity or if there is a complicating nephritis present. He also emphasizes the avoidance of strophanthin in acute myocardial failure, where the heart muscle is without any reserve. The following case has been observed, which illustrates well Rahn's conclusions. In a patient who had suffered previously from myocardial damage bronchopneumonia had developed. Three fifteen minim doses of digitalis and one ampoule of caffeine did not prevent the gradual lowering of the blood pressure and the increase in pulse and respiratory rates. She received one ampoule of strophanthin intravenously for the purpose of combating the cardiovascular collapse. Within one minute after the injection dyspnea, cyanosis, and auricular fluttering developed and the patient died.

The oldest procedure in dealing with cardiovascular failure is the use of caffeine sodium benzoate, camphorated oil, and strychnine. Each drug has its

own province. Strychnine is purely a central stimulant, developing its action on the vasomotor centres. Caffeine simulates strychnine in its central action. On the heart itself it causes a dilatation of the coronary vessels, bringing about an increased flow of blood, at the same time increasing the contractibility of the heart muscle.

About camphorated oil there has been much discussion in the literature. Some workers, Marvin and Soifer (2) and Heathcote Cushny (3), do not attribute to camphor any effect on the heart whatever, while some others give more enthusiastic reports. The reason for this divergence of opinions is the fact that camphorated oil is slowly absorbed and soon inactivated after absorption. Hence the clinical observation of its usefulness is made much more difficult. In order to provide a lasting effect by means of slowing the rate of absorption, some clinicians, Staehelin (4), Deham (5), Schittenhelm (6), Hoseman (7), and others, are using the socalled camphor deposits. They give intramuscular injections of ten to twenty c. c. of a strong twenty per cent. solution and report favorable results. Recently a new way has been worked out, i. e., the intravenous administration, inaugurated by Leo, perfected by the Heidelberg Clinic (Krehl, Gottlieb) (8). They succeeded in producing a water soluble preparation of camphor. This work seems to bring the camphor question into a new light. On account of the slight central effect of camphor it has the advantage of not interfering with sleep, which is not true of caffein and strychnine. During recent years a very effective drug has gained entrance into the armamentarium of the profession, adrenalin. As a heart stimulant it has been given for a long time intramuscularly and intravenously (Jahn, Kothe, and Rosenow) (9). Its intracardial administration was introduced by Van der Velden, Henschen, and Bodon (10) abroad, and by Crile (11) in this country.

The explanation of the pharmaceutical action of adrenalin secured by this latter method is given by Starkenstein, as follows: The stabbing of the heart forms the stimulus for an automatic ventricular contraction, even if the heart beat has already stopped. By this contraction adrenalin is brought into the ventricle and acts on the tertiary centres, developing the revival of their action. As it is carried into the coronary circulation, it restores the primary centres and thus the normal rhythm. Regarding the technic of the intracardiac administration, we have to avoid the different danger zones which are described by Bodon, coronary vessels, sinus node, bundle of His. The area on the left edge of the sternum in the fourth or fifth interspace should be selected for the injection, if heart dilatation is present, a space one finger breadth inside of the left edge of the cardiac dullness. A few points have to be considered in the use of adrenalin as a cardiac stimulant. Adrenalin disintegrates in the blood stream in from five to ten minutes, which explains why one cannot expect a lasting effect and why it is often necessary to further stimulate with strophantine and caffein at once. Pituitrin can be used in a similar way (Cohen) (12). As a heart stimulant it differs from adrenalin chiefly by its constricting effect on the coronary vessels, which are dilated by adrenalin (Morawitz and Zahn) (13). Pituitrin is preferable in cases where abdominal distention, paralysis of the splanchnic vessels, is present.

Everything that damages the heart should be eliminated in cases of cardiovascular collapse. Therefore it is a mistake, in this particular instance, to force fluids by mouth, by hypodermoclysis, by rectal drip or by intravenous injections, which otherwise is a reasonable measure in pneumonia. To continue this symptomatic treatment in the face of the absolute indication we are likely to overtax the circulation and to bring about the last stage of myocardial insufficiency—lung edema. I once saw a colored patient on whom a young physician still continued his routine order to force fluids when the patient was already expectorating frothy sputum.

Another impressive example showing the importance of the recognition for the need of the vital treatment has been observed.

Case I.—Mrs. E. R., forty-seven years old, who had suffered for many years with chronic myocarditis, contracted bronchopneumonia and auricular fibrillation. Besides administering digitalis and opiates, fluids were forced freely, the usual routine measure for pneumonia. Doctors and nurses assured me that the patient would die within the next few hours. After two c. c. of caffein sodium benzoate with restriction of the fluid—intake and restriction of opiates—the pulse could be distinctly felt, which was not possible before, and the blood pressure rose from 52 to 96 within half an hour. With digitalis in conjunction with adrenalin and caffeine for the moments when death seemed imminent her life was prolonged for about three weeks until further administration of stimulants was given up on account of the danger of overstimulation in view of the fibrillating heart.

ANOXEMIA

There is a second condition which forms an absolute indication for treatment—anoxemia. Since this is due to different factors it requires different treatment and should not be combated by routine or standard methods. If we analyze the cause of anoxemia before taking up the treatment, we find that the most frequent type of dyspnea is that which is caused by paralysis of the respiratory centre, due to toxins analogous to and often in connection with cardiovascular failure. We use about the same stimulant measures for reviving the respiration as for the circulation. Adrenalin is an exception, since it chiefly acts on the vascular system. Atropine, however, can be used with greater advantage since it has been proved to be one of the most effectual central respiratory stimulants. Lobelia also, if obtainable in hypodermic form, is of distinct value (Eckstein, Rominger and Wieland) (14). Another type of dyspnea is that of reflex action. The perieheral path of this reflex starts from pleural hyperesthesia, pain or irritating cough, the resulting effect is a paralysis of the respiratory centre (Deham) (5). This type of dyspnea requires analgesics and sedatives. The third cause for diminished oxygen tension in the blood is the deficient expansion of the congested lung, for instance, if there is a great amount of lung tissue involved, as in bilateral pneumonia, or if there is any effusion in the pleural cavity which prevents satisfactory excursion of the lung. The engorgement of the lung may also follow myocardial

insufficiency in consequence of the impaired flow of the lesser circulation.

Especially for this latter type of dyspnea there is one successful therapeutic means at our disposal—venesection. It has been shown nowadays that the old empirical remedy, venesection, will drain any overfilled engorged organ of the body, the congested lung as well as the engorged heart muscle. For this procedure we therefore meet two indications in pneumonia—the lung and the heart condition, and besides it can be considered as a causative treatment directed against the toxemia, because it may aid in eliminating the poisonous substances from the system. It should be mentioned that low hemoglobin and low red cell count is no contraindication to venesection since the anemia in those cases is mostly a relative one, the blood being diluted on account of an involvement of the kidneys. I observed in a few cases that after venesection the red count in the hemoglobin increased in the same proportion as the hydremia lessened.

In some clinics a kind of bloodless venesection is practised—the temporary ligation of the extremities. In this way, large quantities of blood are gathered in the extremities and removed from the overburdened heart and from the lungs. One case has been observed, the details of which may be of great interest.

Case II.—Mrs. F., a case of bronchopneumonia, in whom there developed on the second day of the disease laryngitis, which caused acute laryngeal edema. An intubation improved the patient's condition for a short while, but there was no means of preventing the complete obstruction of the glottis other than tracheotomy. This operation was of benefit for the first day, but one day later heart failure resulted from the double shock of the operation and the pneumonia. The patient was much distressed by the band around her neck, which was applied in order to hold the cannula in position. There was a considerable venous engorgement and cyanosis of the face. In order to make her comfortable, I loosened the band and observed instantly the clearing up of the cyanosis, but the pulse became much weaker and the blood pressure went down. Within five minutes the patient expired. I believe, by loosening the band the large amount of blood which had been accumulated in the head, caused overburdening of the heart and thus produced death.

The other chief measure to save the patient's life in respiratory failure is the administration of oxygen. After ten to thirty seconds the result is noticeable, especially when we use Meltzer's (15) method of insufflation. I am impressed that the best results were obtained in cases with Cheyne-Stokes respiration which often immediately cleared up. Kauders and Porges (16) described a new colorimetric method of determining the degree of anoxemia, with which the value of oxygen in pneumonia is easily demonstrable. In cases of anoxemia secondary to myocardial insufficiency, we can naturally not expect as good results from oxygen as from stimulation of the heart, especially with strychnine and caffeine, which act on both circulatory and respiratory centres.

It has already been mentioned that, if there is evidence of reflex action, pleural pain or irritating cough, causing the dyspnea, analgesics, expectorants, and even opiates are to be resorted to as a lifesaving measure. No other treatment requires as much individualization as this condition, and it cannot be stressed enough that routine administration of morphine for anoxemia is absolutely unreliable. It is experimentally proved that morphine paralyzes the respiratory centre, and manifold clinical experiences confirm this fact (Porges and Kauders (16) and Wassermann, 17). A number of cases have been observed by the writer in which opiates produced definite Cheyne-Stokes respiration instead of obtaining the desired effect of diminishing anoxemia, because the indication for the relief of this type of dyspnea was stimulation rather than depression.

CAUSATIVE TREATMENT.

We have been discussing so far the needs for emergency treatment, the absolute indication. There is, however, a great province for the measures of the relative indication, etiological and symptomatic treatment, provided they do not conflict with the lifesaving therapeusis.

Pneumonia is a disease caused by germs and by their toxins. Everything antagonistic to either one of them, is worthy of consideration in the treatment. In other words, to kill bacteria, or at least to attenuate their virulence, to decrease the amount of poisonous products and to improve the resistance of the organism, are the ways to accomplish this aim. Everybody is familiar with the benefit of the serum treatment based on the experiments of the Rockefeller workers, Cole, Avery, Dochez and Chickering, (18), and of Cecil, (19), and Conner, (20). The anti sera for types two and three failed to be satisfactory; for type four a serum has not yet become available, but in type one cases definite success has been widely recognized. In Cole's reports the mortality rates decreased from twenty-five per cent. to ten and one half per cent. Thomes reports two hundred and fifty cases with twelve and one half per cent. mortality (18).

It has not yet been clearly demonstrated that a good deal of the effect of serum treatment is due to the plain action of foreign proteins as seen in so many other infectious diseases. (Herrick, 21). Friedman, Von de Velde, Veubel, and Bettinger are having some success with horse serum. Schurer and Eimer (22) treated about twenty-four pneumonia cases with casein and milk, and claim to see a similar influence on the course and mortality of the disease as others with serum treatment. These questions have not been entirely solved, neither are the experiments with the pneumococci vaccine yet satisfactory. (Cecil and Vaughan, 23.)

Morgenroth and Levy discovered the drug optochin, the ethyl hydrocupreine which has been proved a pneumococcocide *in vitro* and animal experiments. Clinically it is of value only in the early stage of the disease. Fever drops, and the curve assumes a lytic form. Because of the ease with which poisonous symptoms, especially amaurosis, occur, the doses must be cautiously gauged.

Moore and Chesrey are of the opinion that there are sometimes opotochinfast pneumococci, which are responsible for the occasional failure of its action. There are more optimistic reports on the intramuscular and intravenous use of quinine which is ad-

ministered in conjunction with urethan, as it dissolves very readily in this substance. Ten c. c. of ten per cent. solution were originally recommended by Aufrecht and Cahn (7). Cohen (12), uses quinine dihydrobromide and calls this "the best agent at present available." Barker (24) advises on this subject the use of quinine and quinine products, but, at the same time, evinces skepticism in interpreting their value.

Camphorated oil is also regarded as a specific drug against pneumococci. Animals have been saved by camphor injections after artificial pneumococci infections which produced death in the controls. (Leo, Walk, Boehnke, 4). Klein (24) claims that this action of camphorated oil is brought about by a dilation of the lung vessels. This results in an accumulation of leucocytes, the carriers of ferments which absorb the infiltration during resolution.

All these specific means should not be used collectively. We always have to balance indication against contraindication: e. g., if the heart is low and the fever high, we should not start serum treatment, keeping in mind the danger of further hyperpyrexia. On the other hand, one or two intramuscular injections of quinine or one of its preparations depress the temperature. After three or four days' sickness we should not expect anything by instituting specific measures. For the use of nonspecific protein the greatest caution is always indicated.

In speaking of causative treatment we have to consider the value of elimination. This forms a great aid in treatment according to the clinical experience of many authors. However, I was unable to find an experimental support to uphold this opinion. Cornwall (25) observed a mortality of 30.6 per cent. when he used artificial evacuation of the bowel, against 18.8 per cent. where he did not exert the patient by evacuation.

Regarding forcing of fluids—there cannot be any objection in this as well as in so many other infectious diseases, provided we know when to stop. As stated above, the heart is easily subject to failure in pneumonia and lung edema is the result of exaggerating this measure. We see that the patient generaly desires fluids, and I have learned that this desire is a good measure for the amount which the patient ought to take. In giving saline or glucose solutions by hypodermoclysis or intravenously, besides the administration of à certain amount of fluid to eliminate bacteria or toxins, another factor has to be taken into account. It has been attempted to show that it is the osmotic effect of these solutions which makes them valuable; Meyer and Handovsky (26) proved in extracting the cholesterol amount of the blood plasma that there are definite changes in its colloidal quality to which the excellent effect of the parenteral injections of crystaloids is to be attributed. It is observed that especially high percentaged solutions, forty to sixty per cent. glucose, (Litchfield 27), or ten per cent. sodium chloride are of great benefit.

SYMPTOMATIC TREATMENT

We now have to deal with the third mode of treatment, the means for relief of the patient's symptoms. Most of these methods are very useful and some of them not harmful to the patient. However, in case of emergency they have to recede before the other more important measures. Of outstanding value amongst this group are prophylactic doses of digitalis, since this drug is likely to prevent serious heart complications. There is much discussion in the literature regarding the advisability of giving digitalis, but if it is used in reliable quantities it can hardly do any harm and might be of great benefit to the patient. Levy (28) published the interesting observation that heart enlargement in pneumonia is much less frequent if digitalis has been given before, and this is without doubt an objective argument for its administration.

More complicated is the question of giving opiates. In order to increase the patient's resistance, it is certainly necessary to have him at complete rest, and to relieve his pains and his cough. Kraft and Leitch (29), Reynolds (30) and others, however, demonstrated on rabbits, after administration of opiates, a definite lowering of the body resistance against infection, inhibition of phagocytosis, increase of intestinal stasis, general depression of metabolism. It is a well known fact, that in distinction to all other hypnotics and analgesics, opium and its derivatives are the only ones which act first on the medulla before exercising their depressing effect on the sensory brain centres. (Meyer and Gottlieb.) However, it is sometimes impossible to treat a pneumonia patient without giving opiates. How can we find a way out of this dilemma? Often pains can be relieved by phenacetine, pyramidon and the salicylates, which are especially useful if there is also an indication to lower the temperature. Sometimes, however, we need opiates and then we have to decide just which drug to use. In case of excessive pains we have no other remedy than morphine, but it should always be combined with atropine in order to counteract depression on the medulla. For restlessness pantopon is without doubt the most effectual opiate, since it consists of the five alkaloids and is free from the harmful superfluous bysubstances of the opium. Its content of narcotine especially diminishes its depressing action on the medulla. Morphine itself is no drug for combating restlessness or delirium since its action on the motor centres is preceded by paralysis of the sensory and medulla centres. (Meyer-Gottlieb). In extreme delirium where too large doses of opiates would be required, hyoscine is preferable, since being related to atropine we can ever attribute to it a slightly stimulating influence on the respiration, whereas the higher brain centres, especially the motor, are paralyzed more extensively. The difficulty of attaining a balance between depression and stimulation is illustrated by the following case.

Case III.—Mrs. K., a Polish woman, with bronchopneumonia, which followed childbirth, there developed on the sixth day of the disease violent delirium. She threshed about the bed and wore herself out; fever over 104°, blood pressure below 80. She succeeded in leaving the bed and attempted to leave the room, even after one third grain of pantopon. No persuasion was possible. Five nurses were necessary to hold her in bed until an injection of hyoscine relaxed her completely. As a result of her great exertion and of the artificial depression this patient became completely exhausted and there developed

signs of myocardial insufficiency which required stimulants.

Even in the apparently simple procedure of allaying a cough, we have to individualize. There are two different modes of combating cough, first to stimulate the bronchial membranes and to dilute the secretion in order to procure its elimination. Second, to diminish the expectoration, which can easily be done by the action of codeine on the cough centre in the medulla. Most expectorants, like ammonium chloride, turpentine, menthol, eucalyptus and ipecacuanha have been demonstrated to act in the first way. For the second indication codeine has been proved as the best remedy, its depressing effect being one twentieth that of morphine, and being much less harmful than heroine. The old way of prescribing a mixture of ammonium chloride plus codeine is, at least from the viewpoint of experimental pharmacology, something impossible, since the agents are antagonistic to each other. If there are good clinical results observed, they are due to one or the other. In loose cough with a great amount of expectoration the simple method of elevating the foot of the bed has been advocated by Rautenberg (31), and is, without doubt, a great relief, provided it does not interfere with the general condition of the patient.

A word about the open air treatment in pneumonia! Since about 1900 this treatment has been established, chiefly in this country, as a result of clinical experience (Northrup), little experimental work having been done. It always has been taken for granted that the sole remedial effect in open air treatment is oxygen, until careful studies in recent years have disproved this idea. Russell, Lee and Hill, (32) have brought forth proof of the fact that the value of open air depends largely on its temperature, humidity and movement, its effect in relieving heat stagnation in the body and in lack of cutaneous excitation.

In most houses and even in hospitals we have, in winter, a temperature of over 75° with nearly absolute dryness. I have often wondered if this condition is not one of the reasons why pneumonia is such a frequent disease in this country, and why the mortality from pneumonia in Germany is much lower than it is here (Brooks) (33). We have to consider that people living in overheated houses are facing a marked difference in temperature as soon as they leave their homes, during the winter months. It is not yet definitely proved that the virulent types of pneumococci may not develop from the harmless dwellers of the mucous membranes in the throat. Cole observed, in fifty per cent. of all pneumonia cases infection of the pharynx. Possibly, the ill effect of the dry and hot air on the mucous membranes is one of the chief exciting causes. It therefore follows that open air treatment is commendable if we see a pneumonia patient in such an overheated home or hospital. However, just as much harm can be done in exaggerating this measure. If a patient has 104° fever, or if he is perspiring heavily, we should not expose him to a draft. Regarding moisture, most German clinics use steam in the form of bronchitis kettles, this being a very good protection against dryness. Brooks states that physicians practising in the tropics advise us that their patients do very much better in a warm atmosphere than in cold.

One of the oldest methods is local applications. The term usually used in explaining their action is counterirritation. Irritation means hyperemia and pain, stimulation of sensitory nerves. This latter factor is effectual in procuring a reflex action on the centres of the medulla oblongata and experiments (Roy and Sherrington) proved that an increased blood pressure and a redistribution of the blood is brought about by this reflex. Many clinicians (Huebner and Goldscheider) used such methods as mustard poultices or mustard baths. Against the old, obsolete means which produce any lesion of the skin, such as mustard plaster, cantharides plaster, and others, one must be warned (Brooks). I recall a patient, Mrs. F., who came into the hospital with a most terrible skin infection caused by mustard plaster. If the doctor had seen such burns on otherwise healthy patients he would at least have consulted a specialist, but here he did not even think of bandaging it. The patient became restless on account of this lesion. I saw another patient, Mrs. W., treated with leeches. The physician was unable to control bleeding for two days. The only effect was to lower the patient's resistance markedly. Venesection would certainly have been a much more physiological mode of withdrawing blood.

SUMMARY

1. The importance of the absolute and relative indication in the treatment of pneumonia is emphasized. a. For emergency, it is first necessary to analyze the cause of the present condition—either cardiovascular collapse, or hypoxemia. This analysis should lead us to the treatment, which is absolutely indicated—chiefly stimulation, oxygen, venesection and, in a few cases, opiates. b. The relative indication extends to the measures for specific and symptomatic treatment, i. e., preponderatingly serum administration, elimination, avoidance of dry, dull air, prophylactic digitalis and occasionally sedatives.

2. Frequently some of the second measures interfere with the first ones, which must be carefully deliberated.

3. Routine treatment in pneumonia is never justified and might even accelerate death. This is especially applicable to the indiscriminate use of opiates and the administration of fluids.

The Atomizer in Nose and Throat Work

FRANK B. KIRBY, M.D.,
Chicago.

So important is the use of the atomizer in the successful treatment of nose and throat conditions that it is surprising so little of value is to be found concerning it in current literature and textbooks. Even postgraduate instruction in nose and throat work pays insufficient attention to the choice and selection of the necessary atomizer, nebulizer, steam vaporizer, douche and solutions. The subject is of growing importance because of instrumental improvements and the need for definite instructions from doctor to patient so that none but the best results are obtained.

Unlike most other conditions, it is in nose and throat work that the doctor depends on the patient's cooperation as compared with other treatment where the patient's intervention is absolutely prohibited. Is is, therefore, all the more necessary that explicit instructions be given the patient in getting the proper atomizer, nebulizer, steam vaporizer or douche, the proper solutions to use, and when and how. It is a fair question to raise, is not the medical profession losing much in both prestige and financial return by neglecting to devote the necessary time, thought and work to give the patient that relief for which otherwise he seeks the drugless healer?

We intend a study of the mechanics of the atomizer as a generic term rather than the therapeutics of nasal treatment. This will include the atomizer, nebulizer, nasal douche and steam vaporizer. It seems almost necessary to begin with a paragraph on definitions with the possibility of a subsequent paper on applied therapeutics. Here we would say that possibly nowhere in treatment is it more important to observe the first law of applied therapeutics—do no harm. This is fundamental to the best success.

There is a distinction between the cotton wrapped applicator, as generally used by the doctor alone, though occasionally by the patient, and the other instruments used between office visits even more often by the patient himself. The word atomizer suggests an instrument for applying the medicated solution, oily or aqueous, in minute particles as small as an atom. Of course, such is not the case, so poor is our language, but the thought is a fine subdivision of the remedies selected. A nebulizer differs from an atomizer. The nebulizer is used only for oils and produces a vapor instead of a spray. The rubber bulb pressure in a nebulizer produces a spray inside the container and this spray being volatile gradually vaporizes and passes out of the opening in vapor form. On the other hand, a douche differs in two ways in that it is used as a cleansing agent only, therefore always aqueous and capable of dissolving mucus and always in considerable volume as compared with the spray of an atomizer which may be aqueous or oily. Of course, atomizers are used considerably by both patient and doctor for cleansing purposes.

A word of caution relative to the nasal douche should be given here. It is frequently seen that the ease with which a large volume of solution may be used actually invites trouble, as the solution often enters the Eustachian tube. Instruct your patients in the proper use of the nasal douche, not to throw the head too far back, or better, suggest the use of the atomizer as equally efficient and devoid of this danger.

Atomizers and nebulizers are used by the force of pressure generated either by the rubber hand bulb or an air pressure pump. The steam vaporizer is in common use and most effective for good. With it either an oily or an aqueous solution can be used producing a warm medicated vapor for inhalation, particularly beneficial in the treatment of croup or deep seated bronchial inflammations. The steam vaporizer differs from a nebulizer in that it is operated by an alcohol burner with a wick and the upper container is partly filled with water to which can be added either an oil or an aqueous solution, gum camphor or menthol. Steam is produced and in its exit it carries with it the medication.

Due consideration must be given to the character of the condition to be treated, whether acute, subacute, or chronic. This will determine both a different period of treatment and a studied selection of remedial agent.

To affect the tissues for good, the direct application of sedative, antiphlogistic or protective remedies must be made and this can only follow the cleansing solution by douche or atomizer. Care must be exercised not to harm the mucous membranes by a too harsh contact. The force with which the solution meets the tissue is regulated by the height of the douche bag or the air pressure in the atomizer, either hand generated or by a pump. The direct and immediate effect must be natural or soothing, remembering that the congested area does not have the power for recovery as in tissue with a normal arterial and venous blood supply. The patient must be properly instructed, as extremely gentle contact is conducive to the best results. Foghorn blowing of the nose is certain to engorge the erectile nasal tissue and do more harm than the presence of the increased mucus.

Postoperative anesthesia is always desirable and for both the surgeon's reputation and the patient's comfort, the one dependent on the other, it should be used only after attention to the nasal or throat toilet to insure anesthetic contact. There is no question that full drug action is delayed or prevented by distance betwen tissue and anesthetic. Remove the mucus, foreign body or pus, and immediately apply the anesthetic and the subsequent mucus flow will not increase the discomfort.

We must consider further that laity selfmedication is just as often the reverse of the faulty douche method just referred to, when the oily, protective solution is applied direct to the mucus without first using the aqueous douche. One method is harmful; the other is useless. When the public is so familiar with the word catarrh, even though not fully knowing its meaning, it will pay any doctor to

offer an intelligent, studied method of treatment with full consideration of the importance of the condition which has a definite meaning to the patient.

So much for the cleansing value of the nasal douche or atomizer. As applied to throat work it means the mouth wash and the gargle as well as the atomizer, with the same studied use of selected solutions with full realization of the functions to be performed.

Mention should be made of temperature, as this has a distinct bearing on the end results. Naturally a hot nasal douche or gargle has more solvent power than a cold solution. But where there is obstruction to the return venous channels this might result in further congestion. Generally speaking, a hot nasal douche should be used only in the dispensary or office where immediate local deobstruent treatment can be given. Neither is cold salt solution always effective for good. The continued cold air of the out of doors is less harmful than the alternate cold and hot of the cold douche and subsequent room temperature. Blood heat, meaning normal body temperature, is the choice under ordinary conditions.

It has been suggested above that all nasal cleansing should be followed by a protective antiseptic or anesthetic solution, preferably oily, and this covers the only functions to be considered as follow up treatment. Here is where proper selection must be made for both home and office use. We consider this most important.

Where dichloramine-T is used we require an all glass instrument. The solution should be made up in a small quantity extemporaneously and tested for acidity. If found to be acid it should be neutralized with dried sodium carbonate. An atomizer with a metal tube should not be used but one with hard rubber parts has been shown not to cause appreciable deterioration of the solution. The best protection is the extemporaneous neutral solution.

Following turbinate and sinus work it is essential to treat only the limited area affected. Contact of the solution with the surrounding healthy tissue does no harm, but there is no advantage in wasting medicine. Therefore we suggest the instrument with an adjustable tip so that the spray may be directed up, down or straight ahead. Such instruments are on the market and are a decided convenience.

As now furnished, atomizers may be used for either aqueous or oily solutions, but care should be taken to cleanse and dry them in changing from one solution to the other. The careful operator always has the advantage over the careless, and it pays well to give any necessary attention to insure scrupulously clean atomizers. This is equally true of those with metal parts, as of those which are all glass. We have observed incrustation on atomizers in use in large hospitals and poor or worse results in treatment following their use.

To produce a satisfactory spray or vapor the solution must flow reasonably freely and be able to pass through a very fine tube. Oils of high viscosity must not be used. In fact, they cannot be used, as they require entirely too much force to be sprayed. The same heavy oil that meets the needs of a motor does not cover our requirements for a nebulizer or atomizer, just as all inks are not suitable for your fountain pen.

We must not expect the instrument to do the impossible, but starting with a well selected oil of suitable viscosity we have much of advantage in the successful treatment of the nose and throat as offered by those perfected instruments now available.

In closing, permit a suggestion that more attention be paid to nose and throat work. Patients like to do something. Also, they like to have something done. The policy of watchful waiting for a named diagnosis is meaningless to them. Do something. Give them any necessary local treatment and instructions for their own cooperation in home treatment follow up, and much can be done both as a benefit to the patient and a reputation builder for you.

Focal Infection and Arthritis*

NATHAN P. STAUFFER, M.D.
Philadelphia

At the Presbyterian Hospital the nose and throat department made an intensive study of three hundred patients on focal infections, with special reference to arthritis, our idea being to ascertain if the patients suffering from arthritis had any definite foci, and if so, where they were most frequently situated.

In the ear, nose and throat section we made repeated examinations by the pharyngoscope, the x ray and transilluminations, to determine definitely which tonsil or which sinus was affected. In a group of two hundred cases of arthritis I found that over two thirds of the patients had diseased tonsils, and twenty-five per cent. had sinusitis. By diseased tonsils, I mean tonsils which had caseous deposits protruding from the crypts, coupled with hypertrophy; or tonsils which had encysted abscesses and were markedly hyperemic.

This large number of diseased tonsils in arthritics is certainly a strange coincidence, or a valuable symptom. The question naturally arises, how are they related to the cause of arthritis? The next most common nose and throat lesion was sinusitis, over twenty-five per cent. of the two hundred had pus in their nares or postnares. The striking part of this was the frequency of the posterior set of cells being involved, forty-five occurring in the posterior ethmoids or sphenoids. Obstruction of the nose in the various deviations of the septum were almost as great, being almost twenty-five per cent.

This is important to the rhinologist, as sinusitis

*Read before the Philadelphia Laryngological Society, May 6, 1924.

was found in so great a percentage of these arthritic cases. The teeth were only grossly involved in ten per cent. of the patients. By that I mean objectively decayed roots, unfilled cavities, pyorrhea, or calcareous deposits covering the teeth. The ears were so seldom involved, as to be considered almost nil as a factor. In this series I have divided these patients into the acute and chronic arthritic cases, and the latter I have subdivided into those who can and cannot walk.

In twenty cases of acute rheumatism, I found fifty per cent. of the patients had diseased tonsils, and twenty-five per cent. had sinusitis. None of these had bad ears, or teeth.

In forty-nine cases where the patients were unable to walk the percentage of tonsil trouble was even higher than in the acute cases, for seventy-five per cent. of them had diseased tonsils. In four of these cases, wonderful results were obtained. For instance, Mr. K., bedridden for two years with painful arthritis, had a small pair of diseased tonsils which were enucleated, and he immediately began to improve, and now, four years later, he is walking around an advocate of tonsillectomies. Mrs. B., a hopeless bedridden rheumatic who used a dozen handkerchiefs daily, had a radical Killian, a modified Killian and two Caldwell Luc operations performed before she was cured; and now, three years later, she is rejoicing in her ability to walk everywhere. These examples are likely to make one think all can be cured by these methods, but here comes the strange part, twenty of these forty crippled patients, or fifty per cent., had had tonsillectomies without any appreciable improvement in their ability to walk, or use their hands and feet.

Of course these are all badly crippled patients, some of them unable to feed themselves, unable to walk and some unable even to lift their bodies out of bed without assistance, so far advanced are they with ankylosis of the joints.

These deposits are so thick as to make one lose hope for even an ultimate absorption; it is doubtful if anything will cure them. Their worst symptoms are intense pain with sleeplessness. These complaints were alleviated, and in most cases cured by either the operation, or the treatment which Dr. Pemberton instituted, or the combination of operation and treatment. In another set of chronic patients, of ninety-seven who were able to walk, forty-five had diseased tonsils, and twenty-eight had sinusitis, and twenty-five per cent. had deviated septa.

In these arthritics, the chief complaints were sore throat and postnasal dropping. In the earlier arthritic stages, the tonsils were acutely inflamed or hypertrophied; or the sinusitis patients' discharges were more mucoid, or of a mucopurulent character. In the more advanced stages of arthritis, I noticed the secretions were more purulent or the crusting was more pronounced. The patients in the advanced arthritic stages have a peculiar mousy odor to the breath which is typical of an arthritic patient. It is not a stale breath, nor the breath of the alcoholic habitue. I have never noticed a breath like it except in arthritics. Their mouths and throats are glazed even though they do not have a high temperature, and I concluded it must be some change in the blood which makes the mucosa so dry.

That we might properly judge the value of these arthritic findings, let us consider the patients in one hundred cases of consecutive admissions to the hospital medical wards, and consult their diagnostic cards, the prevalence of nose and throat and mouth conditions in these patients. Of the one hundred patients, sixty per cent. had infections of the nose and throat, fifty-eight per cent. had dental infections, and thirty-four per cent. had genitourinary infections. In the nose and throat infections, the largest number, forty-three, were diseased tonsils, and thirty had sinusitis. These findings were made in patients who were admitted complaining of heart and kidney conditions, and other affections. In these hundred patients, fifty per cent. had a leucocytosis and twenty-five per cent. had anemia.

The most frequent diseases were nephritis, or myocarditis, or a combination of the two. There were many other diseases such as pneumonia, bronchitis, epilepsy, acute rheumatic fever, heart block, perinephritic abscesses, hyperthyroiditis and other conditions. These patients came to the hospital seeking relief for a wide variety of symptoms, the routine examinations bringing to light the fact that those diseases were combined with or due to other ailments, some of which may have been the exciting cause of all their troubles.

It is again significant to find in these hundred cases so many nose and throat complaints, sixty per cent. having nasal and throat diseases. Therefore may we not say that the nasal mucosa, or the tonsils, are many times the entrance for, or exciting cause of, many of our common diseases? Possibly you may think they are only secondarily involved, and quite apart from the disabling disease. While I know that an excess of carbohydrates will increase, or aggravate arthritis, I am of the opinion it is not the sole cause. I believe worry, exposure to cold, overwork plus lowered resistance afford the opportunity for some change to take place in the body metabolism, whether it is a bacterial invasion from some foci of infection or some chemical change in the blood; these are problems which we are trying to solve. I know Dr. Ralph Pemberton has been unable to find bacteria in the joints or fluids of these arthritics, but may that not be due to our technic? Koch could not find tubercle bacilli in a chicken's blood because its body temperature was 104°, but he could in a rat's blood, because its temperature is nearer the human.

In the tonsils examined microscopically and cultured the bacteriologist, Dr. Eiman, reports the great majority of tonsils as showing diffuse suppurative tonsillitis, and the most common bacteria being in the following order: 1. Streptococcus nonhemolyticus; 2, Streptococcus hemolyticus; 3, Streptococcus viridans; 4. Staphylococcus aureus; 5. pneumococci, and 6, bacillus proteus.

Possibly these bacteria may secrete a poison which circulates in the blood or serum, even though the bacteria are not actually present in the tissues in sufficient numbers to be found when an arthritic joint is tapped.

CONCLUSIONS

In concluding I would emphasize:

1. The large percentage of deceased tonsils in this

series of cases raises the question as to whether they may not be a deciding factor. Judging by the acute cases with the large number of tonsil diseases, the tonsillitis may be an early factor which escapes recognition. Possibly the bacteria entering and lodging in the tonsil, or passing through, become active and virulent when bodily resistance becomes sufficiently lowered. Tuberculous experiments on the common sewer rat were without result, until his bodily resistance had been lowered by excessive exercise, fatigue and a starvation diet; then he became an easy prey.

2. In the more advanced chronic cases I believe the bacteria have done their worst and the tonsil removal comes too late. Of course all arthritics do not have discoverable nose, throat, teeth or ear lesions; on the contrary, I can show you many patients with chronic sinsusitis and diseased tonsils who never show any symptoms of arthritis.

3. The large percentage of sinus disease cases in this series is another noteworthy symptom. I think it is worthy of further study, especially in view of the fact that many of these patients have an acute rhinorrhea, whenever they overindulge in sugars, tobacco or overwork.

4. The great rush to extract all teeth in these poor patients I think should be discouraged. I have seen many of them with every tooth gone, unable to masticate properly and not a bit improved, old before their time, hopelessly discouraged. I think it a great mistake to remove all the teeth in these advanced arthritic cases, unless they are grossly diseased. Certainly the indiscriminate x raying and extraction by inexperienced operators, is bound to bring the profession into disrepute unless it is promptly stopped.

5. The indiscriminate tonsil removal is also bad, although their loss is not the hardship on the patient as the loss of all his teeth. In the earlier stages of arthritis, removal of the tonsils may be the deciding factor in starting the patient on the road to recovery; in the later stages of arthritis, I question its advisability.

6. The resulting shock of any operation in these hopelessly crippled arthritics is many times the straw which breaks the camel's back, their nervous system being overwhelmed by the surgical shock plus their added exhausting disease. If operation is indicated, it should be done early and after a period of building up.

I am indebted to Dr. Pemberton, Dr. Talley, Dr. Thomas, Dr. Anigier, Dr. Sailer and Dr. Goodman for the privilege of seeing these patients, and making the collection of these case reports.

2015 WALNUT STREET.

Prophylaxis of Eclampsia*

SAMUEL J. SCADRON, M.D., F.A.C.S.
New York

The progress of modern medicine today is toward the prevention rather than the cure of disease and eclampsia certainly presents a most fertile field for prophylaxis. Acute cases of eclampsia without any premonitory signs are rare and a great majority of cases develop insidiously for a period of weeks.

Rational prophylaxis must be based on a definitely known etiology but unfortunately, as the origin of the disease is still a mystery, we are compelled to apply our preventive measures empirically. Numerous scientists have contributed various speculative theories as to the causation of eclampsia and no sooner is one presented than it is disproved, hence this malady with its symptom complex is called "the disease of theories."

In spite of this fact in recent years much has been accomplished in reducing the percentage of eclampsia with its resulting mortality by proper prenatal care, watchful waiting and frequent special examinations. As this complication occurs only during pregnancy, we assume that the preeclamptic toxemia is due to increased metabolic changes with an accumulation in the maternal blood of the waste products from the fetus or placenta.

To a great extent these underlying clinical facts occur in the early stages of normal pregnancy in a mild form, characterized by nausea and vomiting and other general constitutional disturbances. As the pregnancy advances, and if protective elements are not developed in the patient's circulation, the untoward classical symptoms of preeclampsia, namely, headache, vertigo, high blood pressure, edema and visual disturbances will be precipitated. Keeping this viewpoint in mind one may conclude that there is only a difference in degree between physiological and pathological pregnancy. Every gravid case, therefore, should be looked upon and managed as a potentially eclamptic case.

Certain facts stand out prominently with regard to the predisposition of eclamptic patients. Primiparæ, well nourished and of the plethoric type, are more often affected than multiparæ—pronounced increased intraabdominal pressure in multiple pregnancies and in hydramnios are generally assumed to be predisposing factors; as a rule the increased metabolic disturbances manifest themselves in the later months of gestation.

Various investigators classify the eclamptic state into renal and hepatic types. Those cases in which there is impairment of kidney function predispose the renal type, and those cases with increased intraabdominal pressure and edemas the hepatic type. The clinical picture and symptomatology, however, are the same in both types; hence the difficulty in differentiation. We can, therefore, assume that the increased metabolic changes which take place in the pregnant state are aggravated by overdistention and renal insufficiency, this giving rise to toxemia, as the result of an organic poison liberated by the fetus or

*Read before the Eastern Medical Society, April, 1924.

placenta. This toxin, however, being still undiscovered renders etiology mysterious.

Recent investigators, who advocated the disturbances of the nitrogen metabolism in toxemia with changes in the composition of the urine, have swayed toward the microchemical studies of the blood, attempting to prove the etiology by the retention of the nonprotein nitrogen; their results have not been uniform.

Killian shows that the chemical changes in the blood of nephritic toxemias are typical of the impairment of kidney function in general. There is an increase in the nonprotein urea nitrogen and more than fifty per cent. of nonprotein nitrogen is urea. He found analogous changes in the blood of hyperemesis, postpartum eclampsia, and eclampsia with gravid uterus. The nonprotein nitrogen is markedly increased, whereas the urea nitrogen is at a low normal limit or decreased fifteen to thirty-eight per cent. of nonprotein nitrogen. Cases, however, have been reported by other investigators of high urea retention in the socalled true hepatic type.

The placental theory described by Weichard declared eclampsia to be an anaphylactic cramp. This theory has received the support of many authorities. Zweifel in 1921 by injecting fetal and placental albumen of one animal into another animal of the same species showed that this did not cause any irritability. Thus these tests upset the theory that eclampsia was the anaphylactic reaction of fetal or placental albumen.

The glands of internal secretion play an important rôle in a normal pregnancy, especially the thyroid gland, which frequently becomes enlarged. The studies of eclampsia in relation to the disturbed internal gland function has been a subject of great discussion. Conditions which cause a hypofunction of the thyroid gland in pregnancy would cause increased metabolic disturbances. Many authorities have concluded that the bacterial toxin elaborated in the alimentary canal are absorbed in the blood and carried to the thyroid apparatus on which they act injuriously and cause insufficient hormone production.

A view advanced by Hunter was that this endogenous product of metabolism enters the cerebral spinal fluid through the choroid plexus irritating the central nervous system and producing the condition of eclampsia.

In his recent studies on the parathyroids Massaglia concludes after extensive experimentation that the parathyroids neutralize the waste products of metabolism retained in the circulation. If there is a parathyroid hypofunction the substance that is not converted by the parathyroid goes to the kidneys, but these catabolic substances easily injure the renal tissue which later cannot eliminate the poisons from the body, eclampsia being the final result. Under those circumstances he concludes from a prophylactic viewpoint that the administration of parathyroid extract will fortify the parathyroid glands and increase their power to eliminate the poisons.

A recent rational theory advocated by Zangemeister, which has received serious attention, is the hydrops gravidarum which is based upon a capillary injury followed by an accumulation of water in the tissues. At first there is a preliminary stage of mild edema followed later by severe swelling, especially in the legs. The first stage of pure hydrops is associated with diminished kidney function without albuminuria; the body weight is increased but the blood pressure remains normal. In the second stage a nephropathy with albuminuria occurs, the quantity of urine is diminished and body weight increases still more. At this stage the blood pressure rises gradually until the third preeclamptic stage—headaches, vomiting, visual disturbance and marked hypertension—is followed by eclampsia.

In the management of obstetrical cases prophylactic measures should be taken long before the patient reached the socalled preeclamptic stage. It is advisable for the attending *accoucheur* in every case of pregnancy to inform the patients of the advisability of prenatal care (hygiene of pregnancy, limited good food, fresh air, moderate exercise, attention to the teeth for foci infection and also to the organs of excretion and elimination). We must pay special attention to the symptoms of metabolic disturbances which cross the borderline from physiological to pathological pregnancy.

Practically all pregnant women in the later months of pregnancy suffer from slight edema, especially of the lower extremities, and this is usually attributed to the enlarged uterus pressing upon the pelvic veins. If we find a slight diminution of the urinary output, a rising blood pressure with a slight trace of albumin, even in the absence of toxic symptoms, I consider this a borderline case.

Visual disturbances associated with headache and vertigo must receive careful attention and it is advisable to have the eyegrounds examined by an ophthalmologist for changes in the retina; negative findings of albuminuric retinitis do not rule out this condition as being toxic.

To guard against further trouble, we must recognize the following essentials:

RESTRICTIONS OF FURTHER METABOLISM

Diet.—In normal pregnancy the diet should be limited to one poor in protein as it is essential to relieve the work thrown upon the kidneys by the added burden of pregnancy. If there are any disturbances in metabolism characterized by edemas or nephropathies and increased body weight, one should advise a nonprotein diet altogether—with the reduction of solid food and milk as the basis of general diet. Interesting observations were made in Germany during the war with regard to the diet. The number of cases of eclampsia was markedly decreased as the diet was poor in fat and protein; cases with pregnancy nephritis, which usually predisposed to eclampsia, were favorably influenced by the so-called war diet with marked decrease in the occurrence of eclampsia.

I made some interesting personal observations with regard to the diet in some of the largest clinics in Berlin from November, 1922, to March, 1923. In the clinics with large obstetrical services, there were no cases of eclampsia. The general diet of most patients consisted of vegetables rich in calcium. During the Easter holidays of the same year eclamptic cases were brought into the various clinics. On investigation I found that during the holidays they

permitted themselves a more liberal diet. These observations have a tendency to prove that there is a marked relation between eclampsia and diet, and that a nonfat and nonprotein diet is a valuable prophylaxis in eclampsia.

Edema.—An important element in the prevention of eclampsia is the treatment of dropsical conditions; slight edemas with retention of chloride in the blood with increased bodily weight should receive immediate attention. To combat edemas we must limit fluid and solid diets and if the tendency to edema is increased, a stricter enforcement of the moderation in fluids combined with daily rest hours. Excessive exercise should be avoided; if there is no response to this treatment, absolute rest in bed on a limited milk and vegetable diet should be advised.

Blood pressure.—Increased blood pressure should be regarded as a serious accompaniment of the preeclamptic state especially when associated with edema. The individuality of the patient must always be taken into consideration especially when we deal with vigorous plethoric stout patients, for in these cases we usually have a high blood pressure in the nonpregnant state. At all events a rising blood pressure systolic 140 to 150 is an indication for rest, a salt free and lactovegetarian diet. If after a reasonable time the pressure does not drop, absolute rest in bed and milk diet should be prescribed as prophylaxis. If this hypertension is not relieved by this treatment more energetic means must be resorted to as venesection.

The use of drugs in my experience has had no effect upon reducing blood pressure.

ELIMINATORY PROPHYLAXIS

This consists of the proper attention to the intestinal tract, skin and kidneys. Constipation being a frequent complaint, especially in the later months of gestation, this must be corrected, for autointoxication gives rise to toxic symptoms. After correcting the diet we may resort to the milder form of catharsis, strong cathartics should not be advocated and rectal lavage should be resorted to in the event that the mild cathartics are not effective. Elimination through the skin should be encouraged by daily warm baths taken on retiring.

Excretion through the kidney should be encouraged. From time to time the patient should be instructed to measure the amount of urine excreted. They should normally excrete from thirty to fifty ounces in twenty-four hours. A marked diminution should be noted and reported to the physician. Water being the simplest diuretic should be drank freely providing there is no edema. Urine examinations with regard to albumin, indican, and diacetic acid should be made.

In the event that the prophylactic measures as regards diet, excretion and elimination fail to alleviate the toxic symptoms, especially when associated with high blood pressure, it is advisable to terminate the pregnancy. The initial convulsion should by all means be avoided.

Before concluding I wish to make the following statistical report of cases which occurred in the services of the Jewish Maternity Hospital. Out of twenty-one thousand cases which have occurred between 1909 and 1923 inclusive, we have had 170 cases of toxemia, of which fifty-eight were nephritic toxemia, fifty-four cases preeclamptic and fifty-eight cases of eclampsia.

We have always maintained a prenatal clinic for registered cases—printed instructions in prenatal care are given to each patient. From 1909 to 1918 we had forty-nine cases of eclampsia from our own service. In 1918 our prenatal work was markedly increased, and we were obliged to employ a special nurse to follow up our prenatal cases for we have found while the patients were carefully instructed by the physicians they fail to return for examination. Patients suffering with disturbed kidney function, visual disturbances, rising blood pressure, edemas, and other conditions are admitted to the hospital for observation.

The result of the followup system was a decrease in our eclampsia.

Year	*Deliveries*	*Eclampsia*	*Emergency*
1919	1840	0	0
1920	2022	0	0
1921	2046	4	1
1922	1940	5	2
1923	1862	1	.

In the last five years we can conclude that with the régime of the followup system we have had a marked reduction in the number of eclampsias; our average from 1909 to 1918 inclusive is one eclampsia to 275 pregnancies and from 1919 to 1923, one eclampsia to 971 pregnancies.

CONCLUSIONS

In conclusion I wish to state that while etiology is still a mystery the advance made in prophylaxis has greatly reduced the occurrence of eclampsia.

993 Park Avenue.

Hyperemesis and Hematemesis Following Deep X Ray Treatment of the Lower Dorsal Region.—Tuffier (*Bulletin de l'Académie de médecine,* June 17, 1924) reports the case of a woman in whom an operation for breast cancer had been carried out and sciatic pain on the left side due to metastatic tumor growth at the level of the sixth and seventh dorsal vertebræ had appeared some time later. Deep x ray treatments over the spine were given at intervals for a year, each time with marked but temporary benefit. Finally, obstinate vomiting set in, which failed to yield to any form of medication or diet and resulted in loss of weight, small, rapid pulse, and extreme weakness, with gastric achlorhydria. The vomitus consisted of blood, the pulse rose to 140, without fever, and the patient seemed moribund. Adrenalin, one milligram, was injected subcutaneously, and 0.25 milligram more the next morning. The vomiting stopped after the first dose and never reappeared. Gastric tolerance was restored, the pulse dropped to 80, the patient was able to sleep, and convalescence set in. Acid reappeared in the stomach. The case is reported to direct attention to the risk attending intense, prolonged x ray treatment over the lower dorsal region on account of the possibility of injuring the adrenals and interfering with their function. Where such treatment is necessary because of lesions in this region, the adrenals should be protected from the rays with a sheet of lead and adrenalin simultaneously given.

Practical Therapeutics

BISMUTH IN THE TREATMENT OF SYPHILIS*

By Hans J. Schwartz, M. D.
and Oscar L. Levin, M. D.
New York

Since the publication of C. Levaditi (1) and M. M. Sazerac (1) in 1921, describing the effects of bismuth in the treatment of syphilis, and recommending its use in the attack on biological and clinical syphilis, many experiments have been made and results reported by men to whom this subject has made a special appeal. The original work with bismuth for this purpose was begun by Balzer (2), who in 1899 was the first to experiment with bismuth, with a view to testing out its antisyphilitic properties. Balzer, however, abandoned its use after experimenting on dogs, because of the apparent toxic effect which it produced. The experiments were taken up by many others who became interested and in 1912, at the Congress of French Speaking Dermatologists, thirteen reports were presented on the important therapeutic value of bismuth in the treatment of syphilis. In 1920, Sazerac and Levaditi, the two men who did most to promote the use of this drug as an antisyphilitic remedy, confirmed the successful experiments made by Santon and Robert on the treatment of spirillosis in fowls. Following these trials, these two men made repeated experiments on animals and man with bismuth, which they used in the form of an oily suspension of sodium and potassium tartrobismuthate, known as trepol, showing its rapid cicatrizing action on the various syphilitic lesions. Later, in a pamphlet published in *La Presse médicale* for July 26, 1922. Levaditi confirmed the reports of Fournier and Guenot (3), both of whom did considerable research work in this field, on the favorable effect of bismuth on the Wassermann test; and, Levaditi (4) concluded, from his numerous observations and experiments, that bismuth achieves rapid cicatrization of syphilitic lesions at all stages of the disease; that it cures syphilis; that it is at least equal, from a therapeutic point of view, to arsenical preparations; that it is better than mercurial preparations; and, that it is a valuable antisyphilitic remedy for those manifestations of the disease which resist the action of arsenic and mercury.

A survey of the literature in the medical journals reveals many reports on the results obtained from the use of this drug by many men besides Levaditi and Sazerac, Fournier and Guenot. Bernard (5) and Truffi (6), Nicolas, Mussia, Gate (7) and Pasini (8) and several others all report from observation the rapid disappearance of the syphilitic chancre of the primary stage, after only a few doses of bismuth. Troisier (9) reports his interesting experience with the use of neotrepol on ulcerated syphilitic lesions of the larynx, stating that he observed a rapid and total disappearance of these clinical symptoms in a very short time. Ducrey (10) reports a case in which the bismuth not only brought about a rapid healing of the lesions, even where the lesions had become extremely ulcerated, but also affected a disappearance of the enlarged glands.

Other reports by Grecho (11), Muschietti (11), Spillman (12) and Berthet (13), men who have done much to enrich the fund of information on the treatment of syphilis, show that bismuth not only affects the first stages of syphilis, but in the same startling way clears up lesions of the secondary stages. Thus Bloch (14) reports the successful treatment of malignant syphilis with the rapid disappearance of roseola, papular syphiloderms and condylomata. Veber (15) reports a case in which, after the use of bismuth, all such symptoms as specific jaundice and papular scrotal syphilides cleared up with amazing rapidity.

Going on to tertiary syphilis, several reports by Fournier (16), Guenot (16) and Bloch demonstrate the great benefit derived from the use of bismuth in this stage of the dread disease. In such cases where the patient, during his course of treatment, has built up a resistance to arsenic, bismuth has been found, by Hudelo (17), Milian (18), Marie and Fourcade (19), to be of immeasurable value. Even tabetics in some instances have received considerable relief only from bismuth, and Tixier (20), reports a case of heredosyphilis of the nervous system which was distinctly ameliorated by the use of bismuth injections. J. Cajal and H. Spierer (21) also obtained favorable results in the treatment of hereditary syphilis and found that it may be employed without difficulty in children. They used doses slightly larger comparatively than for adults when treating children.

At the same time that these numerous experiments were being made on the clinical effects of bismuth on syphilis, Fournier and Guenot began to ascertain its actual serological effects and later, Levaditi, confirming their favorable results, concluded that bismuth administered "at any stage of the disease," affects not only the specific symptoms and cutaneous lesions, but also the blood reaction. He shows that in cases receiving treatment when the Bordet-Wassermann test is positive, the bismuth exerts a very favorable influence on the degree of reaction. And, although he does not state that one course of bismuth injections will result in a permanently negative Wassermann test, he asserts that bismuth is at least equal to the other antisyphilitic drugs, and in many respects surpasses them. Bloch in his experiments found that the Wassermann test was not affected to the same degree as the clinical symptoms and he, therefore, employed bismuth together with arsenical preparations and found that the Wassermann test became more rapidly negative.

It is our purpose in this paper to publish the results of experiments made with bismuth (neotrepol) in the treatment of syphilis. We first used trepol, the oily suspension of sodium and potassium tartrobismuthate used by Levaditi in his early experiments, but found this to be too painful in its afteraffects

*From the Department of Dermatology and Syphilology, Cornell University Medical School and Clinic, New York City.

on the patient. We therefore employed neotrepol, a preparation perfected by Levaditi and Sazerac, consisting of metallic bismuth in suspension in a sterile isotonic solution. This consists of ninety-five per cent. metallic bismuth. It is a powerful drug and at the same time is well tolerated. Buccal symptoms following its use are rare, and pain is practically nil. When we first began to use this preparation, we injected it intramuscularly, every four days, in the same way as is done with insoluble mercury, in doses of one half cubic centimetres, increasing rapidly to two cubic centimetres. Later we changed the routine to once every week.

Other preparations like colloidal bismuth and a sodium derivative of trioxybismuthobenzoic acid have been used intravenously. This method of bismuth injections is contraindicated, however, since it produces a toxic effect.

Although we have spoken of the painless character of the drug, we should mention in passing some of the unpleasant effects of neotrepol. Occasionally we met with the formation of a sterile abscess, which seemed to be due to the fact that when the needles were withdrawn, care was not taken to keep the bismuth deep down in the muscle, letting some of the drug escape into the fatty tissue. The muscle should be pressed down firmly with the fingers when the needle is removed so that the skin and fat will not be drawn up with the needle. There were also occasional encounters with stomatitis, which seemed, however, to depend upon the individual patient, and often upon the presence of decayed teeth. In some patients there developed a black line on the gums, near the free margin, as well as the enlargement of black papillæ on the dorsum of the tongue. These minor, untoward effects, however, may be avoided by proper dental supervision of the mouth, the use of a hydrogen peroxide mouth wash, and finally, by the injection of contramine.

Following is a report of some of the numerous cases of syphilis in which we employed bismuth in the form of neotrepol. These cases were selected at random so that we may present a report which will be generally indicative of the entire experimental work.

PRIMARY OR PRIMARY AND SECONDARY SYPHILIS

Case I.—J. M., No. 5849, male, aged twenty-two, clerk, unmarried, admitted to the Cornell Clinic, January 14, 1922, complaining of a generalized eruption. Showed penile chancre and maculopapular eruption. No previous treatment. Wassermann, January 14, 1922, four plus. First course of eight intravenous salvarsan injections and twelve mercury injections. Wassermann, May 11, 1922, negative. Lesions cleared up. Second course of eight salvarsan injections and twelve mercury injections. Wassermann, November 21, 1922, four plus. Spinal fluid, August 22, 1922, normal. Third course of eight salvarsan and twelve mercury injections. Wassermann, March 23, 1923, negative. Fourth course of eight salvarsan and twelve mercury injections. Wassermann, one plus. First course of twelve neotrepol injections, followed by Wasermann, December 1, 1923, one plus. Second course of twelve neotrepol injections, followed by negative Wassermann.

Comment.—Patient had received thirty-six salvarsan and forty-eight mercury injections and blood Wassermann persisted as one plus. Following twelve injections of neotrepol, Wassermann remained one plus but patient stated he felt very much better and had gained weight. Second course of neotrepol produced a negative Wassermann.

Case II.—F. W., No. 22752, male, aged thirty-three, chauffeur, unmarried, admitted to Cornell Clinic, November 21, 1922, complaining of penile chancre. Examination revealed initial lesion on penis, and characteristic macular eruption of the second stage. Wassermann, November 21, 1922, three plus. First course of neotrepol injections. Wassermann, February 13, 1923, negative. Second course of neotrepol injections. Wassermann, April 19, 1924, negative.

Comment.—Patient showed active lesions of the primary and secondary stages with three plus Wassermann. Following course of neotrepol injections, lesions all disappeared and Wassermann became negative and persisted as negative. This case shows the good effects of bismuth on the clinical and serological manifestations of primary and secondary syphilis.

Case III.—J. C., No. 16192, male, aged twenty-six, clerk, unmarried, admitted to Cornell Clinic June 30, 1922, complaining of generalized eruption. No previous treatment. Examination showed multiple penile chancres and typical, generalized, papular eruption. Wassermann, July 3, 1922, negative. Wassermann, July 10, 1922, negative. Dark field examination for spirochetes, July 20, 1922, negative. Wassermann, July 26, 1922, negative. First course of eight intravenous salvarsan and twelve intramuscular mercury injections. Wassermann, January 5, 1923, four plus. Second course of eight salvarsan and twelve mercury injections. Wassermann, May 24, 1923, negative. Third course of eight salvarsan and twelve mercury injections. Wassermann, August 7, 1923, negative. Patient returned, after two months, showing jaundice and recurrent papular, late secondary eruption. Course of fifteen neotrepol injections. Jaundice cleared up during course and eruption disappeared. Wassermann, at end of course negative.

Comment.—This is an interesting case because of the negative serological findings in an active clinical picture, the strongly positive Wassermann developed after the first course of arsenic and mercury and the recurrence of secondary lesions with jaundice after treatment ceased. The clearing up of the lesions and the disappearance of the jaundice, shows the value of bismuth when used in a case with jaundice.

Case IV.—J. O., No. 18309, male, aged twenty-eight, wireless operator, unmarried, admitted to the Cornell Clinic August 15, 1922, complaining of a generalized eruption. No previous treatment. Examination revealed multiple chancres of the penis and secondary maculopapular eruption. Wassermann, August 24, 1922, four plus. First course of eight salvarsan and twelve mercury injections. Wassermann, December 25, 1922, three plus. Second course of four salvarsan and four mercury injections. Wassermann, May 4, 1923, three plus. First course of twelve neotrepol injections. Wasser-

mann, October 22d, one plus. Second course of twelve neotrepol injections. Wassermann, negative.

Comment.—Patient showed active primary and secondary syphilitic lesions with persistent three plus Wassermann. Clinical evidence was removed after twelve salvarsan and sixteen mercury injections, but Wassermann still remained three plus. Following twelve neotrepol injections, there was decided serological improvement and after second course of neotrepol injections, Wassermanns became negative. This demonstrates the favorable effects of bismuth in Wassermann fast cases of syphilis.

Case V.—W. C., No. 18037, male, aged thirty-four, iron worker, married, admitted to Cornell Clinic August 14, 1922, complaining of sore on penis and sore throat. No previous treatment. Examination revealed active secondary syphilitic eruption and penile chancre. Wassermann, August 14, 1922, negative. Wassermann, August 21, 1922, still negative. Active antisyphilitic treatment started August 16, 1922, but after two mercury injections and one salvarsan injection, patient discontinued treatment because he had to leave the city. Wassermann, September 22, 1922, when patient returned, had become three plus. First course of twelve neotrepol injections. Wassermann, December 15, 1922, negative. Second course of eleven neotrepol injections. Wassermann, January 12, 1923, negative.

Comment.—This case of active primary and secondary syphilis with a negative Wassermann, which became three plus showed a disappearance of clinical and serological evidence after bismuth injections.

Case VI.—J. C., No. 17850, male, aged twenty-one, clerk, unmarried, admitted to the Cornell Clinic August 15, 1922, complaining of a sore on the lip. No previous treatment. Examination revealed typical initial lesion on the lower lip and adjacent adenitis. Wassermann, August 15, 1922, four plus. Course of eight salvarsan and twelve mercury injections. Wassermann, December 1, 1922, four plus. Second course of eight salvarsan and twelve mercury injections. Wassermann, March 20, 1923, plus-minus. Third course of eight salvarsan and twelve mercury injections. Wassermann, July 22, 1923, one plus. Spinal fluid examination, March 27, 1923, showed cell count of 14, positive globulin test and colloidal gold test of 345543320. Wassermann spinal fluid, three plus. First course of twelve neotrepol injections. Wassermann, October 16, 1923, one plus. Second course of twelve neotrepol injections. Wassermann, January 8, 1924, one plus.

Comment.—Patient had a labial chancre and a four plus Wassermann which was reduced to a one plus after twenty-four salvarsan and thirty-six mercury injections. After twenty-four injections of neotrepol, the one plus Wassermann still persisted. Patient showed evidence of early involvement of the nervous system, and resisted salvarsan, mercury and bismuth injections.

SECONDARY SYPHILIS

Case VII.—P. M., No. 17509, male, aged fifty-five, porter, married, admitted to the Cornell Clinic August 2, 1922, complaining of sores on the tongue and lips. No previous treatment. Examination revealed mucous patches of the tongue and lips. Wassermann, August 2, 1922, three plus. Course of sixteen salvarsan and nineteen mercury injections. Wassermann, February 27, 1923, three plus. Course of fifteen neotrepol injections. Wassermann, June 26, 1923, three plus. Second course of twelve neotrepol injections. Wassermann, February 8, 1924, three plus.

Comment.—This patient presented a Wassermann fast reaction. He was placed on neotrepol because of the marked stomatitis which he developed after the mercury injections. Stomatitis also developed from neotrepol, and as a result it was impossible to continue treatment.

Case VIII.—A. R., No. 34726, female, aged twenty-six, waitress, married, admitted to the Cornell Clinic July 19, 1923, complaining of a generalized eruption. No previous treatment. Examination revealed a typical papular secondary eruption. Wassermann, July 19, 1923, three plus. Blood Wassermann not affected by course of eight salvarsan and twelve mercury injections. Course of twelve neotrepol injections. Wassermann, January 8, 1924, two plus. Second course of twelve neotrepol injections. Wassermann, one plus.

Comment.—This patient was given bismuth in preference to intravenous injections of salvarsan because of the absence of visible or palpable veins, which made intravenous injections difficult to perform. This demonstrates the advantage of having a drug which can be used intramuscularly, when intravenous injections are difficult. The bismuth reduced the three plus Wassermann to one plus.

Case IX.—H. P., No. 26387, male, aged twenty-six, baggage checker, unmarried, admitted to Cornell Clinic February 20, 1923. Had received eight salvarsan and twenty-two mercury injections prior to admission. Wassermann, February 20, 1923, two plus. Course of six salvarsan and twelve mercury injections. Wassermann, June 5, 1923, one plus. Second course of six salvarsan and twelve mercury injections. Wassermann, October 9, 1923, one plus. Course of twelve neotrepol injections. Wassermann, December 28, 1923, one plus.

Comment.—In this case, the Wassermann was slightly modified by arsenic and mercury, but not affected by bismuth.

Case X.—G. M., No. 4106, female, aged twenty-nine, colored, housewife, married, admitted to Cornell Clinic December 16, 1921, complaining of a generalized, itching eruption. No previous treatment. Examination revealed a generalized, papular eruption and other evidence of secondary syphilis. Wassermann, December 31, 1921, one plus. Spinal fluid examination revealed nothing abnormal. First course of four salvarsan injections and twelve mercury injections. Wassermann, May 9, 1922, two plus. Second course of eight salvarsan and twelve mercury injections. Wassermann, October 19, 1922, still two plus. Third course of eight arsenic, two mercury salicylate and twelve bichloridol injections. Wassermann, May 8, 1923, two plus. First course of neotrepol injections, on September 18, 1923. Wassermann, negative.

Comment.—This case is a good demonstration of the beneficial effects of bismuth in a seemingly Wassermann fast case.

LATENT TERTIARY SYPHILIS

Case XVI.—D. J., No. 22697, male, aged forty, colored, porter, married, admitted to the Cornell clinic December 2, 1921. Had received fifteen arsenic and fifteen mercury injections previous to admission. Wassermann, December 2, 1921, three plus. Course of ten arsenic and fifteen mercury injections. Wassermann, April 13, 1922, three plus. Second course of six salvarsan and eleven mercury injections. Wassermann, July 20, 1922, two plus. Third course of eight salvarsan and twelve mercury injections. Wassermann, January 5, 1923, two plus. Fourth course of six salvarsan and seven mercury salicylate and ten mercuric cyanide injections. Wassermann, May 17, 1923, three plus. Course of twelve neotrepol injections. Wassermann, two plus. Second course of twelve neotrepol injections. Wassermann, one plus. Patient is still receiving treatment.

Comment.—In this case the Wassermann test showed a poor response to mercury and arsenic but immediately reacted to neotrepol injection.

Case XVII.—E. R., No. 3980, male, aged thirty-five, married, admitted to the Cornell Clinic, with history of having had syphilis. Had received various forms of treatment. Wassermann, December 15, 1921, two plus. Spinal fluid, December 23, 1921, showed increased pressure, pleocytosis 50, reduction of Fehling's solution, four plus Wassermann. Twenty-five intravenous injections of salvarsan, thirty-three muscular injections of mercury salicylate and three bichloridol injections. Wassermann, May 11, 1923, two plus. Spinal fluid, May 12, 1923, showed marked globulin reaction, pleocytosis 24, Wassermann test, three plus, colloidal gold, 2233220000. First course of neotrepol injections. Wassermann, reduced to one plus. Second course of twelve neotrepol injections. Wassermann one plus.

Comment.—Patient showed persistent evidence of syphilis in the blood and spinal fluid after arsenic and mercury treatments, but responded slightly to neotrepol injections. Patient is still under treatment.

Case XVIII.—F. D., No. 8650, male, aged thirty-three, lettercarrier, unmarried, admitted to the Cornell Clinic March 3, 1922, with a history of having had syphilis. No previous treatment. Wassermann, March 4, 1922, three plus. Course of twenty-four salvarsan and thirty-six mercury injections. Wassermann, March 20, 1923, still three plus. Course of twelve neotrepol injections. Wassermann reduced to two plus. Discontinued further neotrepol injections because of painful stomatitis.

Comment.—Patient showed immediate serological improvement after bismuth injections, but had to discontinue treatment because of development of stomatitis. This is one of the few cases which showed a stomatitis after the use of bismuth.

Case XIX.—K. M., No. 4427, female, aged twenty, clerk, unmarried, admitted to the Cornell Clinic June 25, 1922, with a history of having had syphilis. No previous treatment. Wassermann, June 6, 1922, four plus. Course of sixteen salvarsan and twenty-four mercury injections. Wassermann, February 26, 1923, still four plus. Course of twenty-four neotrepol injections. Wassermann, August 7, 1923, reduced to three plus.

Comment.—Case of resistent Wassermann test yielding slightly to bismuth.

Case XXII.—J. W. C., No. 43157, male, aged forty, telegraph operator, married, admitted to the Cornell Clinic April 18, 1922, with past history of having had syphilis and having received eighteen intravenous arsenic injections, eighteen intramuscular mercury injections and fifteen subcutaneous injections of arsenic. Wassermann, April 18, 1922, three plus. Course of twenty-eight salvarsan and twenty-eight mercury injections. Blood Wassermann, July 31, 1923, one plus. Course of neotrepol injections. Wassermann, October 26, 1923, three plus.

Comment.—Patient showed slight serological improvement under arsenic and mercury, but none under neotrepol, and was therefore placed back on salvarsan and mercury treatment.

Case XXIII.—U. S., No. 38205, male, aged thirty-eight, metal worker, married, admitted to the Cornell Clinic September 11, 1923, with a history of having had syphilis. Had previously received five years of treatment at Cornell Clinic. Wassermann, September 11, 1923, negative. Course of twenty-two neotrepol injections. Wassermann, negative. Patient relieved of nervous symptoms.

Comment.—This patient came to the clinic with a negative Wassermann, but complained of subjective symptoms which were relieved by the bismuth injections. Spinal fluid examination refused.

Case XXIV.—A. S., No. 7436, male, aged thirty-two, civil engineer, married, admitted to Cornell Clinic upon reference of Life Extension Institute, February 7, 1922. Penile chancre in 1911. Had previously received nine arsenic and four mercury injections, and had been taking mercury pills for four months. Wassermann, February 7, 1922, three plus. Course of eight salvarsan and twelve mercury injections. Wassermann, June 14, 1922, three plus. Second course of eight salvarsan and eleven mercury injections. Wassermann, October 17, 1922, three plus. Third course of eight salvarsan and twelve mercury injections. Wassermann, February 27, 1923, one plus. Fourth course of eight salvarsan and twelve mercury injections. Wassermann, July 14, 1923, one plus. Course of twelve neotrepol injections. Wassermann, October 9, 1923, negative. Second course of twelve neotrepol injections. Wassermann, January 15, 1924, negative.

Comment.—This case shows the value of bismuth as an adjunct to arsenic and mercury.

Case XXVIII.—E. A., No. 2204, male, aged thirty-five, sailor, unmarried, admitted to Cornell Clinic November 25, 1921, with asymptomatic syphilis. Had received twelve arsenic injections previous to admission. Course of four silver salvarsan injections, twenty salvarsan injections. Wassermann, May 5, 1922, one plus. Course of thirty-five mercury injections. Wassermann, January 11, 1923, one plus. Fifteen neotrepol injections. Wassermann, March 23d, negative. Second course of injections. Wassermann, June 12th, negative.

Comment.—This case showed no improvement under silver salvarsan, salvarsan and mercury, but immediately responded to bismuth. However, the spinal fluid which had shown a four plus Wassermann, pleocytosis 75, colloidal gold 0134432100 on August 21, 1922, had not been affected, and on April 4, 1923, was unchanged.

(*To be concluded.*)

Bellevue Hospital in 1874.

Surgery in Bellevue Hospital Fifty Years Ago*

HENRY MANN SILVER, M.D., F.A.C.S.

New York

No attempt has been made to compare the surgery of today with that of fifty years ago. Surgery now is so standardized and practised by all surgeons, the contrast being so great, no comparison is needed. In 1874 Bellevue Hospital was just recovering from a public clamor for the removal of the hospital as totally unfit to house the sick, shown by the great number of deaths from pyemia, erysipelas and puerperal fever, twenty-eight deaths in fifty-three confinements. It was even suggested to tear down the old hospital and erect one on the pavilion plan in its place.

A committee from the medical board was appointed to consider the prevalence of erysipelas and pyemia in the hospital and suggest measures to prevent, if possible, the recurrence of these diseases in the future. The committee reported as follows: Prevent overcrowding by reducing the number of patients; improve ventilation; make the nursing more efficient and increase the number of nurses. In cases of pyemia, in addition to the above, the following suggestions were made in view of the prevalent error in referring the etiology of the disease invariably to hospital miasm. The general adoption of the antiseptic treatment of wounds and immediate removal of the patients from the wards. As a result of the recommendations made by the committee the following changes were made. All cases of pyemia and erysipelas were removed to the pavilion; the number of beds reduced from nine hundred to six hundred; the maternity service was transferred to the Charity Hospital on Blackwell's Island; a training school for nurses was established; the wards were cleaned and fumigated with chlorine gas and special towers were erected to contain the bathrooms and toilets, these having no direct communication with the wards.

The hospital was organized into four medical and four surgical divisions. There were twenty-four visiting physicians and surgeons, there being no associate or assistant visiting. The house staff was small, four house physicians and four house surgeons, each with a senior and junior assistant. Two ambulance surgeons looked after the ambulance service.

The visiting surgeons having no assistants were subject to call any time during the day and night. If they were unable to respond to the call, and, if no other visiting surgeon was available, the house surgeon was directed to call a consultation of all the house surgeons and be guided by the results of the consultation. On the third surgical division the standing orders were that all surgical cases of interest were to be held for the Saturday afternoon clinic provided the life and well being of the patient was not endangered by so doing.

The senior and junior assistants did not reside in the hospital and went off duty at 6 p. m. If any surgical case needing immediate operation came in during the night the house surgeon in charge of the case was obliged to call on the other house surgeons to act as assistants. In those days the service for both visiting and house staff was strenuous, exacting and exhausting but the experience was most varied and profitable.

There were no laboratories for the examination of the fluids of the body, blood chemistry was unknown, urinary examination was made by the junior assistant. There were no x ray laboratories, but there was a dead house where Dr. Janeway made a complete study of diseased and injured tissues. There was no follow up system. None of the bac-

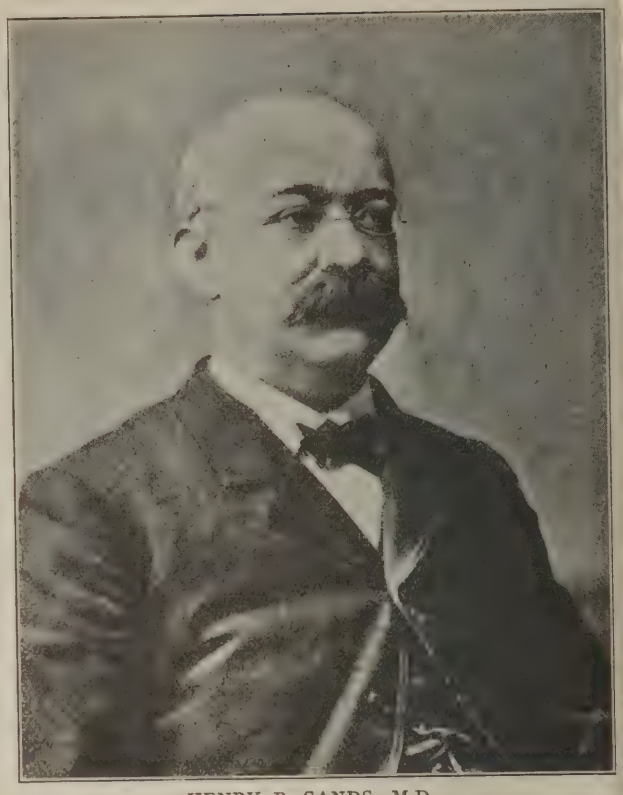
JAMES R. WOOD, M.D.



HENRY B. SANDS, M.D.

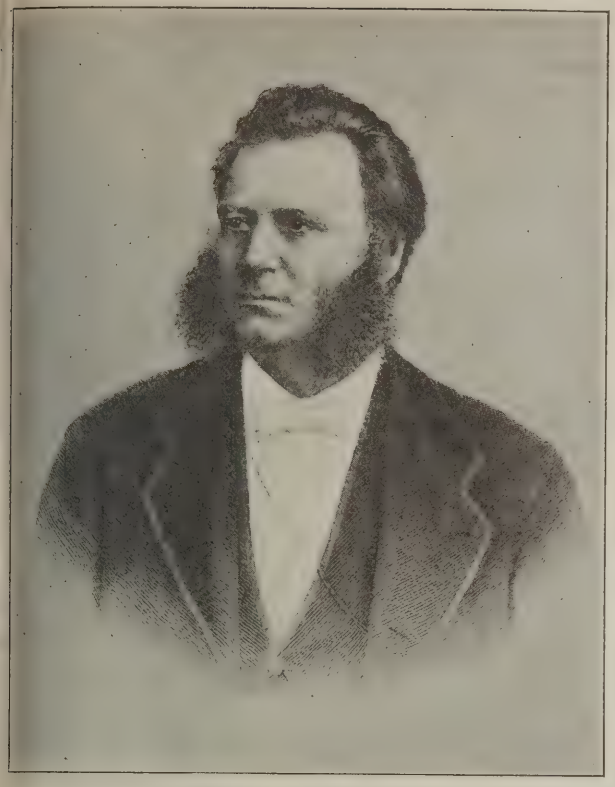
terial causes of the most important diseases had been discovered. In spite of the lack of laboratory facilities, study of the patients, their diseases and injuries at the bedside, was highly developed. In fact, I might say, it was an era of clinical study—in which clinical giants were made.

BACTERIOLOGY

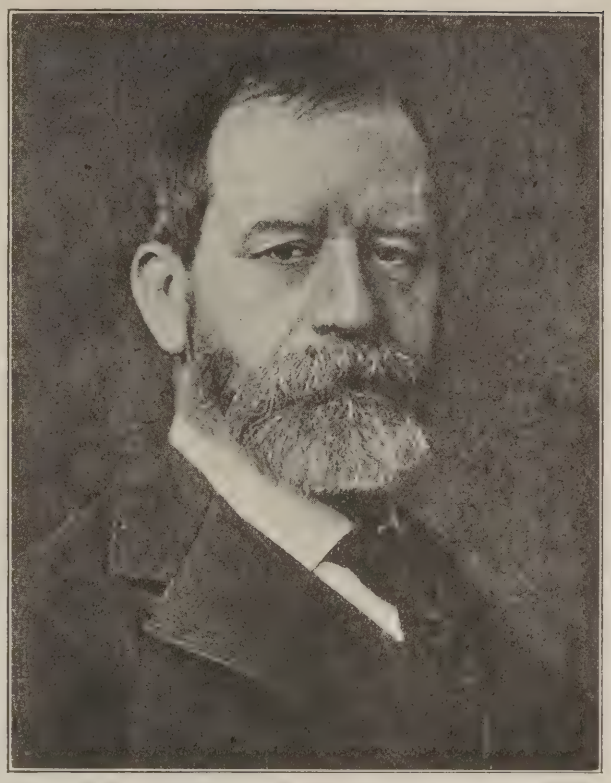
Bacteriology as a science was just being talked of. Acting on the discoveries of Pasteur, Lister in 1871 published his antiseptic method of wound treatment. He endeavored by antiseptic dressings to deprive the atmospheric germs of their septic energy, so that whatever air reached the wound might contain no particles capable of exciting local septic changes. These dressings were practically impervious to air. While the part was being dressed or operated on, a spray of a solution of carbolic acid one to forty was kept constantly playing over it to render inert the germs in the air. Dr. J. C. Warren, of Boston, states that the antiseptic treatment of Lister has virtually been abandoned in this country. No further attempt is now made to prevent decomposition taking place in the fluids collecting on wounded surfaces.

Although the committee in its report strongly recommended the use of antiseptic wound treatment, it was not until 1877 that this method again began to be utilized and then became very popular. Such was the organization and equipment of the hospital, and such was the trend of thought on the antiseptic treatment of wounds among the surgeons of the period when I went on duty as junior assistant on the third surgical division, April 1, 1875. The principal surgical clinic was given by Dr. James R. Wood, professor of clinical surgery in the Bellevue Hospital Medical College. It was held on Saturday afternoons during the session of the colleges and was open to the students of all the colleges. It was generally packed to the doors. The number of graduates from the three colleges in the spring of 1875, was three hundred and ninety-eight. As Dr. Wood had such a great following, there was an abundance of operative material.

Wood would enter the amphitheatre wearing a black silk gown buttoned tightly about the neck and wrists. Over the left breast was a boutonniere of bright flowers. Accompanying him was his house surgeon wearing any old coat, in the button hole of the left lapel were many well waxed silk ligatures, no special care having been taken where the silk and wax had been kept. On a side table a most elaborate display of highly polished instruments with beautiful deeply ridged ivory handles was made. If during an operation an instrument did not please Dr. Wood, he would dash it on the floor and scold the maker who was always present. The anesthetic, ether, was given by the junior assistant from a cone made with a towel and folded newspaper, with a wad of absorbent cotton within. No special preparation of the surgeon, assistants, patient, instruments or dressings was made for the operation. Esmarch's bandage of elastic webbing was used to control hemorrhage. The greatest care was taken to prevent loss of blood following operation. If there had been amputations, the beds of these patients were arranged in a semicircle and a watcher was so placed that he could keep in view the exposed stumps at all times. Under the stump was an elastic bandage ready to tighten at a moment's notice. One of the most interesting parts of the service was the treatment of amputations by the open method. It is so interesting, and, as the results were as good as the same operation performed



LEWIS A. SAYRE, M.D.



EDWARD G. JANEWAY, M.D.

under the most aseptic method of today, it is worthy of a more deailed description.

For over a year all the amputations on the third surgical division were treated by this method, and the results were so surprisingly successful for hospital practice, that Dr. Dennis, in a paper entitled Treatment of Amputations by the Open Method, published in the NEW YORK MEDICAL JOURNAL, January, 1876, called the attention of the surgical profession to this method as the best and safest for amputations in larger hospitals. This method was inaugurated in Bellevue Hospital by Dr. James R. Wood, and to him is due all the credit of introducing and carrying into effect this great reform in surgery. Amputations in large hospitals had for the last few years been attended with a frightful mortality. In fourteen consecutive major amputations performed during Dr. Wood's service within the past year there has not been a death, although the patients occupied the same wards that were vacated a year ago on account of puerperal fever. The method of operating on the fourteen cases was by the lateral skin flaps, circular division of muscles and removal of the sharp point of the crest of the tibia with saw or rongeur forceps. It is important to dissect the flaps long when used in the open method as shrinkage often follows exposure to the air. Esmarch's elastic bandage was employed in every case and in no instance has sloughing or any other complication occurred. A pillow of oakum with a small piece of sheet lint over it is placed under the stump which is allowed to rest on this support until the wound is nearly healed. A small piece of gauze is loosely laid over the stump and a cradle protects it from contact with the bed clothes. The wound is gently douched with carbolic acid solution one to forty at frequent intervals, after which balsam of Peru is poured over the granulating surface. The sheet lint over the oakum being covered with laudable pus is changed frequently. In about a week when the wound is granulating freely and the ligatures are coming away the flaps are gradually drawn together with adhesive plaster. During the entire time of healing of the wound great care is taken to avoid infection. No sponges are used, each patient has his own bottle of balsam of Peru, and, as far as possible, a separate set of dressing instruments; if these were used on another patient they were first thoroughly washed in carbolic acid solution. Each dresser invariably washed his hands in carbolic acid solution after dressing one case before undertaking another, and any one dressing cases in the pavilion or assisting at autopsies was not allowed near healthy wounds. In leaving the stump open and allowing effete material free drainage, the most important factor which produces secondary fever is eradicated and the patient escapes the severe constitutional disturbance dependent upon the absorption of decomposing pus from a closed wound. In all the cases reported, including amputation of the arm and even the thigh, no patient has shown a temperature higher than 103° and many of the cases have been below 99° during the entire period of convalescence, with the exception of one or two nights. In comparison with the major amputations treated with a closed stump, the temperature ranged from 104°-105° and often rose to 106°.

TREATMENT OF TUMORS OF THE BREAST

In most of the cases the tumor had been present more than a year, and there was retraction or ulceration of the nipple. The clinical diagnosis was scirrhous cancer. All were operated on by the oval

method, the upper part of the incision looking towards the axilla. The tumor mass only was removed unless there were enlarged glands in the axilla; these were dissected out with the handle of the scalpel and finger. Only a small quantity of blood was lost in all of the cases. Whenever a vessel was divided, hemorrhage was controlled by finger pressure until forceps were applied. At the clinic, after removal of the tumor, a towel was packed into the wound and the patient removed to the ward, where the towel was removed and the open wound exposed to the air to allow it to glaze over and check oozing. After the clinic the house surgeon would scrape away the clots in the wound, tying or twisting any bleeding points and bring the edges together with silver wire sutures an inch apart, reinforced with strips of adhesive plaster between the sutures. The ligatures were brought out at the upper angle of the wound, this being the most dependent part when the patient was lying down. Compresses of folded towels held in place by a broad bandage passing around the chest were placed on each side of the line of suture. The forearm was placed in a sling. The dressings and adhesive strips were changed every day. If the edges of the wound looked red, compresses of lead and opium wash were applied. The highest temperature, 102°, usually appeared on the second, third or fifth day. Thirty drops of McMunn's elixir of opium was always given the first night, repeated if necessary, to give the patient a good rest. Ligatures began to loosen about the sixth day, if they were slow in coming away gentle traction was made, which gave rise to great pain if a nerve was included in its grasp.

House Staff of the Third Surgical Division.
H. M. Silver, surgical assistant; F. S. Dennis, house surgeon; A. Pell, junior assistant surgeon.

It was not until twenty years later when Halstead in November, 1894, and Willy Meyer in December, 1894, published their articles on the radical operation for cancer of the breast, that a ray of hope came to those suffering from this dread disease.

FRACTURES

Large numbers of fractures were treated fifty years ago in Bellevue Hospital. Earlier in the paper, it was stated there were at that time no x ray laboratories in the hospital, the substitute for their service resided in the gray cells presiding over the special senses which, in the surgical visiting staff, were developed in the highest degree. Their finger tips when examining a fracture seemed to have eyes capable of seeing everything pertaining to the fractured bone. Great attention was paid to the careful measurement of a fracture before the treatment was begun and after the splints were removed.

Femur.—All fractures of the femur on Dr. Wood's division were treated with Buck's extension until all signs of inflammatory swelling had disappeared, rotation of the thigh being prevented by a long side splint extending from just below the axilla to beyond the foot, where it was attached to a cross piece. After two to eight days a plaster of Paris splint was applied, great care being taken to pad the perineum and bony points. To strengthen the splint, pieces of strap iron were placed in the spica at the groin. Forcible extension with compound pulley under ether was not necessary. On Dr. Sand's division the plaster dressings were applied early to prevent inflammatory swelling by the moderate and uniform compression to the broken limb afforded by the dressing, but one must be on the lookout for any signs of impaired circulation; if they appear the whole length of the splint should be slit up. When the plaster dressing is applied early it may be necessary in many cases to make extension with the compound pulley under ether, keeping up the extension until the plaster hardens. For cleanliness, the upper part of the splint when dry was painted with melted paraffin. The splint was generally removed in six weeks, the average shortening in fifty cases being three eighths of an inch. Dr. Sands placed a plaster splint on a case of fracture of the femur just below the trochanter major with the leg and thigh flexed (double inclined plane) with a very satisfactory result. Volkmann's counter extension bar was used for counter extension during application of splint.

Leg.—The larger number of fractures of the leg were of the compound comminuted variety, caused by a wheel of a horse car passing over the leg. These cases were carefully explored with the finger and usually condemned to amputation. In less serious injuries, if the wound was small it was sealed with a cotton and collodion dressing and the leg placed in a fracture box well padded with oakum. The simple fractures were also placed in a fracture box. When all signs of inflammatory swelling had disappeared, they were put in plaster of Paris casts extending from the toes to the knee. The cast was fenestrated opposite the wound, if compound, and tube drainage was provided if necessary. Dr. Sands held the same views for the early

application of plaster dressings in fractures of the leg as he did in fractures of the femur.

Colles's fracture.—Dr. Wood insisted that all Colles's fractures should be treated with well padded lateral splints extending from the wrist to the elbow,

D. L. Wallace, C. P. Smith, H. M. Silver, and C. H. Thomas.
House Surgeons at Bellevue Hospital in 1874.

in order to avoid stiffness of the wrist and fingers. We followed Hamilton's direction in reducing the deformities by making forcible pressure on the back of the lower fragment, the force being applied near the styloid side of the fragment. The splints were allowed to remain in use for five weeks, being removed from time to time for massage treatment. Hamilton's work on fractures and dislocation was our guide in treating most of the fractures.

ABDOMINAL SURGERY

Surgery of the abdomen was a closed book. Dr. Wood was bitterly opposed to operation for pistol shot wounds of the abdomen, preferring to use the Clark or opium treatment. It was not until the evening of November 2, 1894, when Dr. William T. Bull opened the abdomen for a pistol shot wound and successfully closed eleven perforations of the intestines, that surgery of the abdomen for pistol shot wounds became an open book. Dr. Dennis on December 20, 1895, opened the book for stab wounds.

STAB WOUNDS

In stab wounds, three or four feet of intestines generally protruded. Covered not infrequently with bar room sawdust. These were washed if necessary, and replaced, the wound being carefully closed. The patient was placed under the influence of opium at once and the quantity of food reduced to a minimum. If shock was present at the time of admittance, hypodermic injections of whiskey were given, the hot air bath used, and, if the shock was severe, the extremities were rubbed with tincture of capsicum. If tympanites developed, turpentine stupes were applied. If the intestines had escaped injury, this treatment was successful. I do not remember a single case of typhlitis or perityphlitis on the third surgical division during my service. In those cases occurring on other divisions the patients were treated with poultices, exploring needles and Parker's operation, if pus was found. Dr. Sands was very much opposed to the operative treatment of perityphlitis and was needlessly cautious in recommending laparotomy even as an exploratory procedure in early cases. Several years later he became an enthusiastic operator. It was not until the classic article on appendicitis by Reginald Heber Fitz of Boston, Mass., appeared in 1886 that the fear of operations on typhlitis and perityphlitis, together with these terms, were thrown into the surgical scrap heap.

HERNIA

Radical cure of indirect inguinal hernia. Whenever a patient with a hernia unreduced entered our wards he was placed in a position now called Trendelenburg's position and taxis made with or without ether. If the hernia was one suitable for radical cure, operation was recommended. The method used had this object in view, viz.: to cause an adhesive inflammation between the invaginated scrotum and sac and the tissues of the inguinal canal and internal abdominal ring. This was attempted by the use of Wützer's instrument. The hernia is first reduced and held in place by an assistant, the operator then invaginates the scrotum into the inguinal canal with the hollow cylinder of wood, a part of

R. F. Hine, H. Goldthwaite, J. C. Cochrane, and J. C. Kendall.
House Physicians at Bellevue Hospital fifty years ago

the instrument. A flexible gilt steel needle fixed on a movable handle and connected with the wooden cylinder is thrust forward through the invaginated scrotum, the peritoneal sac, and through the anterior wall of the abdomen and enters an opening in

the narrow wooden pad which rests on the skin over the inguinal canal. The instrument is held in place with lateral pads and a spica bandage, and is allowed to remain in place six or eight days when it is removed. The cul de sac made by invaginating the scrotum is stuffed with lint and the parts supported with a spica bandage. The patient is kept in bed four weeks with a broad bridge of plaster across the thighs just below the scrotum; now, when out of bed, a truss is substituted for the bandage. Hamilton states this method was well received and used by many surgeons, but he doubts the efficacy of the procedure.

In the first case so treated, the instrument was removed at the end of a week. Signs of superficial sloughing of the skin were found as a result of pressure of upper part of splint. There was little pain; the highest temperature was 99° and there were no signs of peritonitis. A week after the instrument was removed the patient got out of bed without permission and the hernia came down again.

GENITOURINARY SURGERY

The genitourinary cases were most interesting. Varicoceles were treated by amputating the redundant scrotum. Epididymitis was treated by rest in bed, tobacco-poultice, later by strapping. Cases of stricture were numerous, and many of the sufferers were sailors who had not been able to have treatment while at sea. The cases became more interesting the tighter the stricture. Remembering Syms's dictum that whenever urine passed out through a stricture an instrument could be passed in, our ambition was to pass a whalebone guide through the stricture; sometimes hours would be spent in accomplishing this. The following was our technic. Warm sweet oil was forced into the urethra and kept there with finger pressure. The whalebone guides, some with points bent or twisted so that their extremities would be outside the axis of the shaft of the instrument, were passed as far as they would go, their points engaging in lacunæ or false passages. This was continued until one entered the bladder or the urethra was full. Then each guide would be gently raised up and down and rotated until one entered the bladder. On this, a small tunneled catheter or sound was passed. If it was found impossible to dilate the stricture with the tunneled instruments, an external urethrotomy was done, followed by the passage of large sounds at frequent intervals.

Three night nurses of the first class in the first training school for nurses in America.

Extravasation of urine was treated with long and deep incisions in the scrotum. Retention of urine from enlarged prostate, if not complete, was treated by the use of the rubber catheter, French olivary gum catheter, or silver catheters with an exaggerated prostatic curve; if these instruments failed, one of the best methods to be tried next was one in which a metal stylet curved to suit the case is inserted into a gum elastic catheter, the instrument is introduced down to the prostate, the stylet slowly withdrawn an inch, at the same time the catheter is gently pushed onward. The increased curve thus obtained allows the point of the instrument to surmount the obstacle and enter the bladder. Great care was taken not to empty the bladder too quickly. In the presence of complete retention, the urine is withdrawn with a Dieulafoy aspirator, the capillary trochar being introduced just above the pubes.

ORTHOPEDIC SURGERY

We also had a large and interesting orthopedic service with Dr. Lewis A. Sayre. After a very careful study of the histories of the cases mentioned and many others found in the records, I noticed that in spite of unfavorable surroundings and lack of any special preparation for operation, the histories ended with the statement —"This day the patient was discharged cured." Was this due to the greater resistance on the part of the patient, to greater care in the after treatment by the house staff, or were the germs less virulent on account of the simpler mode of living at that time?

PERSONNEL

Before closing this paper I want to call your attention to some numbers of the visiting staff I came in contact with who made a lasting impression on me. They moulded the surgical thought and practice of the day. You will notice they all possessed those outstanding characteristics which make great men in any walk of life.

James Rushmore Wood was a man of wonderful personality; a great anatomist; a rapid and skilful operator, whose results were brilliantly successful. He had great power of clinical observation and diagnostic acumen. His energy was unfailing and he was always on the alert to detect and combat any unfavorable sign. The tripod on which he rested his treatment was rest, cleanliness and free drainage. Although stern and unyielding on the professional side, he always carried with him the warm and helpful side for all those worthy of it. His house staff, private students and patients adored

him. He was an inspiration never to be forgotten.

Henry Berton Sands had the power and charm of a great personality. He had a singular acuteness of intellectual vision and was rarely deceived by sentimental considerations, personal predilections or by accepted tradition. He was a master of anatomy. He was a rapid and skilful operator, selfpossessed in the presence of every emergency and fertile in resources. His unerring judgment and a certain diagnostic instinct gave him a fame which outleaped the barriers of his home city. His marvelous industry and unimpeachable punctuality, conjoined with loyalty to his profession, and an ever present modesty, made him a favorite consultant with his professional brethren far and near. He had the largest number of private students of any surgeon in New York. His cheerful and confident entrance into the operating room appeared to prove to house staff and students that all that brain of man could devise or the hand of man execute would be put forth for the welfare of the patients.

Lewis Albert Sayre also had a wonderful personality; he was of powerful build and had a keen searching eye. His unflagging enthusiasm for his work, his interest in the house staff and patients inspired confidence and aroused a like enthusiasm in those who came in contact with him. His enthusiasm knew no bounds when he was speaking of his success in treating spinal diseases with the plaster jacket, or late stages of hip disease by excision of the hip joint. He was a wonderful teacher of orthopedic surgery, in fact, orthopedic surgery as a specialty began with his teaching. He took as much interest in eaching his house staff in the wards as he did the students in the amphitheater. Those who knew him only superficially were apt to consider him rough; he was blunt of speech and made no pretence to diplomacy, but those who saw him at close range knew there was a warm and tender side to his heart. He was a great favorite with children. He had an enormous amount of material from which to derive his experience, as thousands of the city's poor passed through his hands. To him belongs the credit of introducing the use of oakum into surgical practice. Just after his graduation in medicine while he was dressing a wound in a tenement house, the dressings gave out. While thinking what to do, he noticed some tow sticking out of an old lounge; this with balsam of Peru completed the dressing. This makeshift started the use of oakum in surgery.

Edward Gamaliel Janeway had a great personality of quiet reserve. He was one of the committee which studied and reported on the causes giving rise to the prevalence of puerperal fever, pyemia and erysipelas in the wards of the hospital. During this period he was showing a phenomenal assiduity as a pathologist. He was doing the hardest kind of work, combining clinical study in the wards with study of appearances presented post mortem. He always went to the root of the matter. He was a keen observer and an excellent interpreter. He showed almost superhuman detective power in ferreting out the hidden causes of disease, combined with wonderful zeal and enthusiasm for his work. His accurate diagnoses were due to his rare qualities of mind and to his tenacious memory, a memory which stored up every experience, so that when he made a diagnosis that seemed difficult—he would say—he knew he was right because he had seen a case just like this before. He spent himself unselfishly for others, he was as kindly and gracious to the poor as he was to the rich. He was always ready to aid the surgical house staff and, if they could not open the abdominal cavity while the patient was alive, he would demonstrate the points of interest in the dead house. As the years passed, Dr. Janeway's skill in diagnosis increased until just before his death he was recognized as the greatest diagnostician in the world.

In conclusion, I want to return thanks to Professor Frederick Shepard Dennis, my house surgeon fifty years ago, for the use of his copy of histories taken during his service, also for the use of reprints of papers on the treatment of amputations, but most of all for advice given during the preparation of this paper.

111 East Thirty-ninth Street.

A Pope as Physician.—Probably very few persons, even members of the medical profession, know that one of the Popes had exchanged the physician's hood for the papal tiara. Dr. David Reisman (*Annals of Medical History,* December, 1923) writes of his researches into this historical matter. For church and political reasons, a conclave of cardinals in the year 1276 elected to the Papacy a Portuguese physician, Petrus Hispanus, already cardinal bishop of Tusculum, as Pope John XXI. According to nearly all writers of ecclesiastical history, he should have been John XX, since there were apparently only nineteen Johns before him. James Branch Cabell, in his characteristic way of culling tidbits for his fantasies from historical odds and ends, fashions the "cantrap" given by the "Master Philologist" to Jurgen for use as a charm, out of this discrepancy: "At the death of Hadrian V, Pedro Juliani, who should be named John XX, was, through an error in reckoning, elevated to the papal chair as John XXI."

In the Middle Ages, the name of Petrus Hispanus was a medical household word. He was the son of Julianus, also a physician, and first appears as a student in the University of Paris, where he was probably made *magister.* About 1247 we hear of him as teaching medicine at Siena, where he wrote his first medical work, *A Dietetic Treatment of Surgical Patients,* and probably did some practising. As a native of Portugal, where the Moors were still in power, he doubtless understood Arabic, which accounts for his works on Avicenna and Isaac Judaeus. His greatest medical work was the *Thesaurus pauperum,* printed for the first time in 1476 in Antwerp. "The Thesaurus," writes Reisman, "is a collection of recipes for every disease under the sun. It had an enormous vogue in the Middle Ages. Being copied and recopied before the discovery of printing, every copyist added his own favorite prescriptions until the work finally became a hodgepodge of medical treatment and magical formulas of the most grotesque sort."

Petrus Hispanus tried his best to exclude from his works superstitious and sympathetic remedies, but his successor, Arnald of Villanova, included in his book remedies against demons and evil spirits.

Editorial Articles

PHYSICAL LABOR AND AGE

That hard physical labor after the age of forty definitely tends to shorten the life span, has been shown by Dr. Raymond Pearl of Johns Hopkins University in a recent series of investigations. Pearl states that this unfortunate relationship between hard work and duration probably holds in graded degrees after middle age for nearly every walk of life, whether the labor is performed chiefly out of doors or indoors, and "the weight of the evidence supports the view that hard work itself is the primary cause rather than any general environmental factor arising from social class distinctions." The collection of the proper raw statistical material on which to base such a study appeared, says Pearl, "to be a hopeless task until we obtained certain extremely valuable statistics on the mortality of occupied males published from the offices of the Registrar of England and Wales. These data fulfilled most of the requirements and may be fairly regarded as the most comprehensive and accurate statistics of occupational mortality now in existence."

The statistics covered 132 occupations and a period of three years. So that mortality trends according to age might be studied, the death rates were grouped in five year periods. Five rather loose classifications according to the approximate amount of physical energy expended were adopted, and in addition indoor and outdoor groupings.

The first results of the analysis, which dealt with young men working indoors, showed no harm from hard work—"in short, it appears very difficult to kill a man by physical hard work before he is forty, occupational and industrial hazards being excluded. But after forty is passed our results tell an entirely different story." From thirty-five to forty-four, the death rate in heavy occupations showed itself to be 3.9 per cent. higher than that for the light occupations. In the period from forty-five to fifty-four it rises to 12.8 per cent. greater; from fifty-five through sixty-four to 18.6 per cent. greater. Workers in iron and steel industries, blacksmiths, stokers, and all others included in the heaviest class of indoor work become progressively more and more unlikely to attain a ripe old age after forty. Among the lighter occupations were included those of insurance agents, messengers, gamekeepers, and drivers of coaches, cabs, omnibuses and automobiles; among the heavier occupations, dock and wharf laborers, coal heavers, quarrymen and coal, tin, iron and lead miners. The death rate of the latter class from the age of thirty-five through forty-four is 3.2 per cent. higher; from forty-five through fifty-four is in 12.6 per cent. higher; and from fifty-five to sixty-four inclusive, 24.8 per cent. higher. "Although the death rate of the outdoor workers in general is lower than that of all indoor workers, the same relation between heavy and light occupations and the duration of life is evident. . . . There only remains the question of whether environmental conditions arising from social class distinctions may have been the primary factor instead of hard physical labor. Rearrangement of the data indicates clearly that such is not the case, though it is quite true that social class is often correlated with the degree of physical exertion which a man may put forth in his daily work."

Pearl's researches seemed to indicate that the same relation between physical exertion and the duration of life holds good for women as well as men. Arnould, he tells us, recently pointed out in France that the fall in the tuberculosis death rate in recent years has been relatively greater for men than for women, and he attributes this to an increasing tendency to tuberculosis among women caused by hard work.

FIFTY YEARS OF MEDICINE

The reflections on progress in medicine by an acknowledged leader of the profession, and one who has been in the van for many years, should be always interesting and attract attention. Sir David Ferrier, the well known nerve specialist who has had, probably, the unique experience of giving the introductory address at the opening of the session of a London hospital medical school fifty years ago, and of giving the address at the opening session of the same hospital on October 1st of this year.

He reviewed, as was fitting, some of the progress made in medicine and surgery during the period he covered. He concluded, however, that no matter how great the advances made had been, the essentials in the art of medicine were unchanging, and that it would be a great misfortune, in spite of all the modern aids to diagnosis, if the simple or unaided methods of diagnosis, such as percussion, auscultation, and the like, should be neglected. It was pointed out that there had been noted a tendency on the part of the younger generation to neglect the simpler methods and to rely too exclusively on aids which might not be available at the critical moment. While delicate physical and chemical apparatus were necessary in the clinical laboratory, the results must be incorporated with those of other methods and

capable of application by the practitioner in the ordinary course of his work. The various methods should supplement but not supplant each other, and as we saw clearly only what we were prepared to see clinical vision should be sharpened rather than dulled by the light of science.

A similar situation exists with regard to scientific pharmacology. Sir David Ferrier insisted that this did not necessitate the abandonment of purely empirical methods which long experience had proved to be of value in the relief of suffering. There were many remedies now out of fashion, which were still relied on, and apparently on good grounds by physicians of ripe experience and sound judgment. Nor should the study of the scientific bases of medicine ever be divorced from the most thoroughgoing study at the bedside. The human body was a much more complex organism than that of the lower animals and infinitely more so than any mere physical or chemical compound. The living body was, as Prof. H. H. Dale had said, in many ways an essential partner in its own cure. The most suggestive part of Sir David Ferrier's address, however, was that which dealt with the psychical side of man and its influence on the physical side. The impulses and emotions by which he was swayed, constituted a factor which highly complicated the action of all the remedies of the *Pharmacopœia*. Though much valuable work had been and is being done in this direction, as yet we knew comparatively little as to the mode of origin and channels of transmission of these corporeal influences; but it was certain that the pleasurable emotions, such as faith and hope, exalted while the depressing emotions, such as fear, doubt and anxiety, depressed all the vital functions. How to promote the one and combat the other was often more a mark of therapeutic skill than a judicious selection from the *Pharmacopœia*.

It is assuredly wise to dwell on the fact that the essentials of the art of medicine are unchanging and that while progress in treatment and therapeutics has been made it is well not to discard all the old methods and drugs. After all, the gift of correct diagnosis gained partly by intuition and partly by experience backed by sound clinical knowledge are the most valuable possessions of a medical man whether he be specialist or general practitioner.

Many leading men of the medical profession, including Sir James Mackenzie, have uttered the warning that too great reliance should not be placed on laboratory methods valuable as they are. Laboratory methods should be the handmaidens or complements of clinical experience and not regarded as the sole arbiters or the last word and the only things which really mattered in making a diagnosis. The same may be said of modern drug treatment. Some of the old remedies have shown by the acid test of experience that they serve a useful purpose, in spite of the fact that it is not understood clearly how they act. Indeed, it is likely that drugs when they act successfully do not act directly, but indirectly by stimulating the natural forces of the body to defend it against the invaders. And it is becoming more and more evident that psychical influences are of the first importance in combating disease.

Fifty years of medicine have shown great progress but all the old fashioned views have not been overturned completely, in truth, many of these views appear to be in process of rehabilitation.

THE ETIOLOGY AND NATURE OF GOUT.

Gout is certainly as old as civilization, and yet, despite its antiquity, we must still admit with Aretæus the Cappadocian, that its secret origin is known only to the gods. Of a verity, as the illustrious Sydenham observed, "No very limited theory and no one particular hypothesis can be found applicable to explain the whole nature of gout." A confession not devoid of pathos seeing that he was a lifelong martyr thereto, albeit deriving solace from the reflection that the disorder "destroyed more wise men than fools." From the clinical viewpoint, Sydenham's classical description of gout is unsurpassed, but not until the isolation of uric acid by Scheele (1776), and its detection in tophi by Wollaston, did physicians begin to realize that in some obscure way the life history of gout was bound up with that of uric acid. But when Garrod (1848) revealed the existence of uric acid in the blood of the victims of gout, its presence therein seemed then and for long after an all sufficient explanation of its protean manifestations. In 1913, Folin and Denis introduced their exquisite colorimetric test and thereby established the fact that uric acid—in demonstrable amounts—is constantly present in human blood. Consequently, in gout there is a condition, not of uricemia, but of hyperuricemia. What is its significance? For, admitting that the blood content of uric acid in gout is above normal, nevertheless, the excretion of uric acid, save during acute attacks, rests within physiological limits.

Again, as to the assertion that the blood is surcharged therewith, we have the awkward fact as yet inexplicable on chemical or physicochemical grounds, that the bloodstream can hold in suspension far more uric acid than has ever yet been met with in gout, according to Bechhold and Ziegler no less than fifty mg. of uric acid to one hundred c. c. of blood serum before deposition tends to occur. On the other hand, urates are less soluble therein,

not exceeding two and five tenths mg. to one hundred c. c. How remote from the limit of saturation the highest figures observed in gout! What a large margin of solubility is still available! Again, the uric acid blood content in gout is far less than was formerly thought. Only by a few milligrams does it transcend that found in normal individuals. Can this slight disparity have such profound potentialities as to determine the incidence of gout? And this with the saturation point still so remote. The urates, too, being practically nontoxic, how difficult to conceive that the almost trivial excess of the uric acid blood content over the normal is adequate to produce the fulminan and dramatic phenomena of acute gout. All the more so when we realize that no constant relation has as yet been established between the uric acid content of the blood and acute attacks of gout. Again, no variations in the same apparently herald or accompany typical acute paroxysms; while attacks may occur with a subnormal uric acid blood content.

Confronted by these and other difficulties, Llewellyn holds that uricemia is not the cause, but the result of gout. Also that the fulminant character of the acute gouty crises postulates the intrusion of some other factor—more vital or biological.

Developing his theme he affirms his belief that gout is invariably inherited and that its hereditary transference consists in the transmission of a tendency to protein sensitization. He has the less diffidence, he says, in making the suggestion seeing that more often than not, gout develops on a soil already sensitized—as betokened by the fruit already borne in the shape of asthma, urticarial and eczematous eruptions, or some one or other of the toxic idiopathies now known to be often attributable to protein sensitization. Reflection upon the clinical interactions and alternations of articular gout with these disorders lends weighty support to Llewellyn's hypothesis. He advances very cogent reasons for his belief that the food idiosyncracies of the gouty are due to protein sensitization, and that the disturbances in nuclear metabolism are secondary thereto. He obviously has no faith in purin free diets. The salient point, he says, is not whether or not the diet be purin free, but does it contain the specific protein or proteins to which the particular gouty patient is hypersensitive? For, as he clearly shows, in gout as in asthma, every man is a law unto himself.

A true iconoclast, he goes still further in his exposure of the prevalent fallacies in respect to alcohol and gout. He boldly affirms his belief that whether it be malt liquors or wine, it is not their alcohol content that evokes gout. He suggests that in beer the responsible constituent is not the alcohol, but the hordenine or some other protein in malt. Again, that those in whom gout develops after consuming this or that wine are hypersensitive to one or other of the proteins contained in the different races of yeast cells, concerned in their fermentation. Or that they are sensitized to the protein substances introduced in the process of fining wines, i. e., such well established antigens as white of egg, casein, and skimmed milk. This eclectic attitude on the part of an authority of wide experience is most welcome. The marvel is that the notoriously erratic response of the gouty to different wines had not long since suggested a corresponding discrimination on the part of physicians in prescribing wines for these subjects. It cannot be denied that these reflections are not only highly original, but most illuminating.

Again, Llewellyn draws attention to the fact that lead may evoke gout, either through its ingestion, its inhalation, or its absorption by way of the skin or mucous membranes. Hence he pertinently asks, why should not the proteins of barley or other cereals act in like fashion? For, judging from statistics, gout is as common among coachmen, grooms, stablemen and farm laborers, as in draymen, malsters, brewers' laborers, and so forth. In other words, gout develops with significant frequency in those whose work involves the mere handling of grain. Now, cereal proteins, we know, may —by inhalation or absorption—induce asthma in some persons, then why should they not in other instances, like lead, evoke gout, and this by direct contact? May not the socalled gouty throat be the outcome of sensitization by direct contact of the proteins in malt dust or yeast spores? If so, it would explain why tonsillitis or pharyngitis in some and in others conjunctivitis or episcleritis so often usher in a classical outbreak.

Again, Llewellyn draws attention to the striking parallel that obtains between the arthritic and cutaneous phenomena of serum sickness in those of regular and irregular gout. He believes that the joint swellings of gout, like those of serum sickness, would be more accurately described as arthropathies, than as arthrites. He clearly shows that the evolution of classical gout presents many anomalies difficult to reconcile with the orthodox development of an arthritis. He holds that for the production of a true gouty or uratic arthritis there is required, not only a specific gouty soil, but an equally specific mode of pathogeny. Basing his contentions on Dale's researches he holds that the basal morbid mechanism responsible for gouty arthritis is one of vascular endothelial poisoning, and this latter the outcome of anaphylaxis—the responsible antigen being either of bacterial, animal, or vegetable origin.

Unquestionably, if we accept cellular sensitization as the basal pathological change in gout and that it achieves its malign effect through vascular endothelial poisoning, the conception does dissipate much of the mystery attaching to gouty metastases. For, obviously on this basis the symptoms of gout will naturally vary with the regional distribution of the circulatory stasis, and the structure and function of the organ or tissues implicated.

Time and space forbid further discussion of this brilliant contribution. We would, however, add that, like Llewellyn, Chauffard, of Paris, discussing the acute crises of gout finds them reminiscent of acute attacks of asthma, migraine, and urticaria—"all paroxysmal illnesses and allied to gout by certain clinical affinities." Basing his remarks on the researches of Widal, Chauffard looks on acute gouty paroxysms as precipitated by a disturbance of the colloidal equilibrium, very similar to anaphylactic reactions, with special modification in the number and percentage of the leucocytes, of the blood pressure, and albuminoid content of the plasma. "I think," he says, "that it is along these lines that we must search for the explanation for the acute crisis of gout."

THE SIGNIFICANCE OF HYPOTENSION

Much is talked and written of hypertension nowadays but comparatively little is heard of hypotension. As a matter of fact, although overshadowed by high blood pressure, low blood pressure is equally as much of a symptom and is associated with almost as many abnormal conditions as and occasions perhaps more inconvenience than high blood pressure, except when this is extreme. It would be possible within the limits of an editorial to run over the various conditions which may cause low blood pressure, but there is little doubt that the defective working of the internal secretions exerts a considerable amount of influence upon its causation.

A diminished secretion of the adrenals is likely to bring about a lowered pressure. In Addison's disease, for example, where the glands cannot function to their full capacity on account of their diseased condition, this happens. In the menopause there may be an increase or decrease of blood pressure. In many of the cases where a hypotension exists the symptoms have been allayed by the daily use of corpus luteum extract of ovarian substance with a resulting increase of pressure. While it is difficult to say how the hypotension came about, it may be suggested that the diminished ovarian function has temporarily upset the secretion of the adrenals, the ones which have a distinct effect on pressure and that when the lacking ovarian substance was supplied equilibrium was reestablished. Many of the socalled nervous derangements of women are characterized by low pressure. It is likely that here, too, we may be dealing frequently with disturbances of internal secretions.

Certain it is that raising the pressure generally relieves the symptoms, such as headaches, mental depression and loss of energy and vitality. In many of these cases, except in those indeed in which the disturbance is obviously of nervous origin, it is well to consider defective working of the internal secretions and glandular therapy. It may, however, be noted that subnormal blood pressure is more often an indication of derangement of the vasomotor centre than of cardiac impairment. May not the primary cause often be constipation, intestinal stasis resulting in a toxemia which prejudicially affects the smooth working of the internal secretions and thus affecting the nervous system, a prominent symptom of which is a lowered blood pressure?

If this is so the rational treatment of hypotension is to rid the system as far as is possible of the circulating poisons, by suitable diet and by bringing the functions of excretion and elimination into proper working order and perhaps by using certain glandular preparations. While hypotension has been neglected by the medical profession, it has a significance, although its significance cannot be always determined. The subject is one which will amply repay a close study and throw light upon many now obscure points.

THE AMERICAN HEART ASSOCIATION

Although the American Heart Association is less than five years old, it had, at the beginning of 1924, forty-eight clinics with a total of 6,879 patients in attendance, and was cooperating in its work with thirty-two of the hospitals of New York City.

The association was formed in 1915 as an outgrowth of the work for handicapped workers whose hearts could not keep pace with their ambitions or their need of self support, and with encouragement from the field of public health, where studies of the increase in heart disease showed the need of a new preventive and relief service. The first efforts of the society, which then bore the name of the New York Association for the Prevention and Relief of Heart Disease, were directed to diagnosis of the sick and education of the well, with such success that today the cardiac clinic is recognized as an indispensable part of every well developed hospital or dispensary. The United States has 140 such clinics. It was not until 1922, however, that during a meeting of the American Medical Association it was decided to form a national body. A committee was appointed to consider the type of organization best suited to the purposes of the work and to take the

steps necessary to its formation. This committee consisted of Dr. Paul D. White of Boston, Dr. James B. Herrick of Chicago, Dr. Joseph Sailer of Philadelphia, Dr. Hugh McCulloch of St. Louis, and Dr. R. H. Halsey and Dr. Lewis A. Connor of New York. It was decided that no attempt at an organic union of local associations with the national body should be made, but that their interest and support should be secured by providing for the enrollment of their members as voting members in the national association by the payment of nominal dues.

The body was incorporated, and in the same year cardiac children were placed in fresh air homes for the first time. During the year forty thousand pieces of literature were distributed and forty-two lectures given on heart disease. Trade classes were started in 1923 as an annex to the Manhattan Trade School, to which eighty-two girls were admitted. Many of these girls came to the classes as truants, originally excused from school because of heart conditions, pampered by overindulgent parents, and careless and indolent in their attitude toward life. In 1924 boys of the same type were added. A thorough examination of the children in one of the city continuation schools, including seventy-one boys and 837 girls, disclosed the fact that fifty-four had some definite form of heart disease. During the same year the Committee on Schools completed a survey of the work for cardiac children in the public school system, and made the recommendation that it would be better to have more thorough medical supervision of all school children, including many with slight and often curable heart trouble, than it would be to expend funds as at present on special classes of cardiac children where they are segregated from normal, healthy children.

The Associated Clinics came into the association in 1924 as a committee of the association, and has formulated uniform standards for clinics, held meetings for social service workers in cardiac clinics, and done much other work.

FOOD IN HOUSE REFRIGERATORS

A study of bacterial changes in relation to temperature and humidity in relation to food in house refrigerators has recently been made by the departments of biology and of foods and cookery of Teachers College, Columbia University. A report of this study has been contributed to a recent issue of the *Nation's Health* by Jean Broadhurst and Mary B. Van Arsdale. In the experimental work special consideration was given, first, to the range and constancy of the main factors, temperature and humidity, in three different types of refrigerators; and, second, to the related variations in the bacterial content of foods under known temperature and humidity conditions.

To summarize the conclusions it was found that, 1, in house refrigerators with constant air circulation, fairly constant temperature and relative humidities may be obtained; 2, continuous circulation of the refrigerator air is essential to secure throughout the lowest temperatures and the lowest relative humidities of which a given refrigerator is capable; 3, the temperatures obtained in many house refrigerators are distinctly favorable to the multiplication of bacteria and other microorganisms; 4, bacterial multiplication varies directly with refrigerator temperatures rather than with relative humidities, the depression due to low relative humidities being more than overbalanced by attendant high temperatures.

Five recommendations are therefore made to insure sanitary refrigeration in the home: 1, house refrigerators should be constructed so as to insure constant and complete circulation of air. No dead spaces nor air pockets should be permitted to exist; 2, the ice chamber should be large and kept well stocked; the larger the ice surface, the more contact there is with the circulating air, and the greater the effect upon the air; 3, thermometers should be supplied for the warmest and the coldest shelves at least. Milk should be kept at temperatures below 45° F. Temperatures of 60° or more mean that the ice box is acting as an incubator rather than as a refrigerator; 4, since cold air is relatively heavier than warm air, careless management of the doors may allow much of the cooled air to fall out of the box. Watch the thermometer to verify this; 5, milk and similar foods should be kept as cool as possible. The warmer the shelf and the longer the stay in the refrigerator, the greater the bacterial content and deterioration of the food. Such bacterial changes are not without danger to the consumers, especially babies, using stale milk.

HEALTH DRIVE IN BELLEVUE-YORKVILLE DISTRICT

To add twenty years to the span of average life in the community is the avowed aim of a health demonstration in the Bellevue-Yorkville district in New York City, to be undertaken by the Milbank Memorial Fund. This section of New York City is situated on the East River, extending to Fourth Avenue, and bounded on the North and South by Sixty-fourth Street and Fourteenth Street respectively. The demonstration will be carried on with the cooperation of hospitals, social organizations, clinics, the city's welfare agencies, and other organizations and institutions standing for health and welfare purposes. Approximately two million dollars will be spent in financing the drive. All agencies of the above type willing to cooperate will meet and elect a smaller group to direct the undertaking and appoint an executive board. They will submit their budgets to this committee for advice as to expenditures so that duplication will be avoided. In cases where financial aid is needed, appropriations will be made to both public and private agencies in addition to the amount they are already spending, but they will not be permitted to decrease these expenditures, the appropriations being made only on the condition that the resources of the agency are such as to prevent it from providing adequate service from its own funds.

News Items.

Memorial Service for Dr. Robinson.—A service in memory of the late Dr. Andrew Rose Robinson will be held at the New York Polyclinic Hospital and Medical School on Sunday, December 7th, at four o'clock.

New York Tuberculosis Conference.—The third annual meeting of organizations interested in tuberculosis was held in New York on November 20th, sponsored by the New York Tuberculosis Association.

Institute for Midwives.—An institute designed to raise the standard of midwives was recently held by the New Haven Department of Health and the state department of health.

Bulletin of Surgical Clinics.—An arrangement has been made for posting each evening on the first floor of the Academy of Medicine, an announcement of the surgical clinics to be held the next day in the hospitals of New York.

Medical Society to Include Dentists.—Dentists may be admitted as associate members in the Philadelphia County Medical Society. The first joint meeting of physicians and dentists will be held at the College of Physicians, December 12th.

George Robert White Fund Health Unit.—The dedication of the George Robert White Fund health unit, at Baldwin Place, Boston, was dedicated on November first. The will of Mr. White provided five million dollars to Boston for the creation of works of "public utility and beauty." Dr. Charles V. Wilinsky will be in charge of the centre.

Convalescent Facilities.—A conference has recently been held at the invitation of Dr. Frederick Brush of the Burke Foundation, to discuss facilities for the convelescent care of colored patients. As a representative of the Sturgis Fund, Dr. Brush announced a gift from the fund of one thousand dollars as a nucleus for meeting this need.

Aerial Hospitalization.—Colonel Uzac, director of the medical service, French War Ministry, and Colonel Picque, professor of anatomy of the Bordeaux Faculty of Medicine. presented an exhibition of motion pictures showing the advantages of aerial transportation of the sick and wounded, in a meeting held at the Army and Navy Club of New York, November 24th.

Eye Institute at Johns Hopkins.—The trustees of Johns Hopkins University have joined the Wilmer Foundation in a campaign to establish a three million dollar endowment for an eye hospital and school, for treatment and research. It will bear the name of Dr. William Holland Wilmer, of Washington, and will be directed by him. One million dollars are to be devoted to the building and equipment, the free hospital beds, and the teaching of ophthalmology. Two hundred thousand dollars was contributed some time ago by friends and patients of Dr. Wilmer, incorporated as the Wilmer Foundation.

New York Academy of Medicine.—The following nominations for officers have been made by the New York Academy of Medicine: president, to serve two years, Dr. George E. Brewer; vice-president, to serve three years, Dr. Charles A. Elsberg and Dr. Frederic T. Van Beuren; recording secretary, to serve three years, Dr. Fenwick Beekman; member of committee on admission, to serve five years, Dr. Arthur M. Wright; member of library committee, to serve five years, Dr. Russell L. Cecil; trustee, to serve five years, Dr. George David Stewart; the election will take place at the regular December meeting.

Gorgas Memorial.—There are at present being organized governing committees for the furtherance of the Gorgas Memorial—on the basis of one hundred members to every million population in each state; seventy-five per cent. of the personnel consisting of medical men. These state committees in cooperation with the national executive committee will supervise the permanent activities of the memorial. An endeavor is being made to raise an endowment of five million dollars, the interest being utilized for carrying on the work. Founder members of the state committees are requested to subscribe one hundred dollars, and each member of the state committee is to be a contributing member. When the medical organization is complete, a general appeal for funds will be made. The memorial is primarily a medical movement.

Journal Discontinued.—The *Journal of Medical Research,* published for many years at the Boston City Hospital, has been discontinued. It will be succeeded by the *American Journal of Pathology.*

Dental Exhibit. — An elaborate exhibit on mouth hygiene is being held at the old Astor Library building, arranged by the Allied Dental Council. There has been a weekly average of twenty thousand visitors.

Hospital Fund Map.—The United Hospital Fund has issued a map giving the location of the hospitals of greater New York, both members and nonmembers of the Fund, as well as dispensaries, health department stations, etc.

New York Skin and Cancer Hospital Alumni.—Alumni of the New York Skin and Cancer Hospital and of its postgraduate school are requested to send their present professional office addresses to the secretary of the reorganized alumni association.

New Editor Appointed.—Dr. Henry O. Reik, former president of the American Institute of Medicine and editor of the *International Medical and Surgical Survey* has been appointed editor of the *Journal of the Medical Society of New Jersey,* succeeding the late Dr. David C. English.

Lecture by Doctor Draper.—At a meeting of the American Stomatological Association to be held Thursday, December 11th at 8:30 p. m., a paper will be read by Dr. John W. Draper of New York, on "Stomatology and Preventive Surgery." Discussion will be by Dr. Redford K. Johnson of New York and George C. Fahy, D.D.S., of New Haven.

Tuberculosis Health Crusade Awards.—The nine silver cups donated by the National Tuberculosis Association as awards to states, counties, and cities for high standing in the Modern Health Crusade work have been awarded, four to Iowa, two to Florida, and one each to Massachusetts, Oklahoma, and Wyoming. The cup for cities of 100,000 population and over was presented to Oklahoma City.

Endowment for University of Rochester.—Gifts of $2,500,000 from George Eastman and of $1,000,000 from the General Education Board of the Rockefeller Institute are announced as part of a campaign for endowment of the University of Rochester. Alumni have nearly reached their goal of raising $1,000,000. The school of medicine, which will admit its first class next September, is building on land adjacent to the Oak Hill site.

Psychiatric Centre.—Arrangements have been completed for the building of a psychiatric centre for research and treatment of patients, by cooperation of the State Hospital Commission and the Joint Administrative Board of Columbia University and the Presbyterian Hospital. The new institute will be built on the plot of land at 165th street and Broadway, on which other buildings of the medical centre of Columbia and the Presbyterian Hospital group are to be built. It will replace the institute and hospital now located on Ward's Island. There will be beds for from one hundred and fifty to two hundred patients, selected as cases of scientific interest. The State Hospital Commission is planning to expend at least $1,500,000 and will make such a recommendation to the Legislature in January. This sum is available under the bond issue for state hospitals.

Personal.—Dr. George L. Meylan, of Columbia University, represented that institution at the celebration of the fiftieth anniversary of the founding of the Ecole Polytechnique of the University of Brussels, November 20th.

Dr. Nicholas Kopeloff, of the Psychiatric Institute of the Manhattan State Hospital, has returned to this country after a year's research at the Pasteur Institute, Paris, and other institutions.

Dr. George H. Simmons, for more than twenty-five years editor of the *Journal of the American Medical Association,* and now editor and general manager emeritus, has started on an extended trip to Europe and India.

Dr. Thomas F. Abercrombie, Atlanta, Georgia, has returned from the world conference on preventive medicine at The Hague, to which he was a delegate from this country.

Dr. Frederick W. Derby, of Boston, has received an appointment as ophthalmologist of the Boston department of health.

Dr. Henry A. Stone, of Philadelphia, has begun eighteen months' service at the Rockefeller Foundation Hospital of Peking, China.

Foreign Correspondence.

LONDON LETTER

(From our own correspondent)

London, *October 27, 1924.*

JUBILEE CELEBRATIONS OF THE LONDON SCHOOL OF MEDICINE FOR WOMEN

On the evening of October 24th there assembled in the Guildhall, London, a remarkable gathering to celebrate the jubilee of the London (Royal Free Hospital) School of Medicine for Women attached to the University of London. The particular celebration took the form of a dinner and as Miss Aldrich Blake, dean of the school, said in graceful acknowledgment of the hospitality of the City of London Corporation in placing the Guidhall at the disposal of the women doctors and their guests, it was an historic privilege to dine in that historic hall on such an historic occasion. It is understood that this is the first time that a function of this kind, with women doctors as hosts and men as guests, has been held in the venerable building. Dean Inge, of St. Paul's Cathedral, known throughout Great Britain as the gloomy Dean on account of some pessimistic views on things in general but who is easily one of the best writers and speakers in the country, proposed the first toast "Women's Work" and said in part that the art of relieving suffering seemed to come naturally to women and brought out the best side of their nature. It was the literal truth that the man was unhappy who, when he was sick or weary, had no woman at his side. He could not speak from personal experience as to the skill of women in the medical profession. He was ashamed to say that he had reached the age of sixty-five years without hardly ever consulting a doctor. In some operations the small and delicate hands of women could have a distinct advantage over those of men. At the same time they must forgive him for saying as a mere man, that the highest and best work of a woman was that of a wife and mother, and when he looked at the troop of young women he saw making their way into that hall that evening, he hoped they were not all sworn to celibacy.

Lady Barrett, who is one of the most distinguished graduates of the Women's School of Medcine, said in part that most people were coming to see that public work done by one sex was rather like work done by a person blind in one eye. Two eyes were required, looking at things from slightly different angles. In time to come the whole world would, she thought, realize that what these difficult times required was the vision that came from complete humanity, and not the vision that came from the work of either one sex or the other.

Mrs. Fawcett, widow of the late well known blind postmaster general and sister of Dr. Garrett-Anderson, one of the founders of the London School of Medicine for Women, and herself one of the ablest women of the country, in responding quoted a speaker, who she said was as distinguished a man as Dean Inge, at a dinner given by the International Federation of Medical Women last July. He said that he had from long observation discovered that the main difference between men and women doctors was that medical men paid great attention to symptoms, while medical women aimed rather at discovering the causes and prevention of disease. She thought that was the most tremendous compliment that could be paid to women doctors.

Professor G. A. Gardner, Vice-Chancellor of the University of London, proposed the toast of the London School of Medicine for Women and Miss Aldrich-Blake, dean of the school with whose name it was coupled, responded. Professor Winifred Cullis proposed "the Chairman." Dr. Scharlieb, in her reply, said that if Dr. Sophia Jex-Blake were with them that night she would rejoice to see the abundant fruit of her labors. She thought she would bid them consider three things: The friends of the school, the future of the school and the funds of the school. They were not anxious about the future of the school. The puny infant of 1874 had thriven; convulsions and teething disasters were no longer to be feared; the spirit of the school was adolescent; it was sound and vigorous enough to survive the psychological troubles of that epoch and it gave promise of fruitful maturity. The future of the school was in the hands of the students. Those who knew them best felt assured that they would be in all respects worthy of the vocation to which they were called. All would not be easy, but the end was sure, and the medical profession might be satisfied that the women would play the game and maintain its good traditions.

Nearly 600 were present at the dinner, among whom were Sir Humphry Rolleston, president of the Royal College of Physicians, Sir George Newman, chief medical adviser to the Ministry of Health, Sir Edward S. Schäfer, professor of physiology at the University of Edinburgh.

On the afternoon of October 25th, Princess Beatrice and Princess Arthur of Connaught were at the Thanksgiving Service "for opportunities for training, work and service opened to women in the last fifty years," held in St. Paul's Cathedral, in connection with the jubilee celebration of the London School of Medicine for Women. About three thousand women, representing every profession and calling, were present. The scene in the cathedral was deeply impressive. At the opening of the service a procession representing the links which bind the past to the present generation was formed, and moved up the aisle. Among these were Dr. Mary Scharlieb, president of the school; Mrs. Henry Fawcett, walking with her niece, Dr. Louisa Garrett Anderson. The nearest surviving relatives of Dr Sophia Jex-Blake, her two nieces, Miss Henrietta Jex-Blake, principal of Lady Margaret Hall, Oxford, and Miss Catherine Jex-Blake, former head of Girton College, Cambridge. The procession also included The Countess of Minto, representing the medical and nursing services of India, Professor Sir Charles Sherrington, president of the Royal Society; Lord Dawson of Penn, Lord Riddell, president of the Royal Free Hospital; Dr. A. Louise McIlroy, professor of obstetrics and gynecology Royal Free Hospital; Lady Barrett, consulting physician to the Royal Free Hospital; Dame Janet Campbell, Ministry of Health; Dr. James Berry

consulting surgeon to the Royal Free Hospital. The sermon was preached by the Bishop of Lichfield, who referred to the proposal to erect at the London School of Medicine a lasting memorial to the three pioneer women doctors, Dr. Elizabeth Blackwell, Dr. Elizabeth Garrett-Anderson and Dr. Sophia Jex-Blake. It is proposed to raise an endowment fund of £50,000 to endow three chairs, in anatomy, physiology and pathology in memory of these three women. It may be said that the fund now stands at £26,000 and that donations will be gratefully accepted from those interested in women's work and especially women's medical work in America.

COUNTRY HOME FOR SHELL SHOCK PATIENTS

Designed to afford individual treatment to men who have received shocks to their nervous systems by war experiences, the Sir Frederick Milner Home at Beckenham near London has been formally opened by the Duke of Connaught. It is a country mansion with several acres of lawns and sheltered wooded surroundings and the Ex-Service Welfare Society, who secured it for this purpose, could not have chosen a more beautiful locality. Sir Frederick Milner, chairman of the movement, has been imbued throughout with the necessity, on grounds of common humanity, for some provision being made for men on the mental border line who might otherwise have to enter an asylum or remain in the homes or relatives or friends with no knowledge of the treatment required for such cases. It is a comparatively small effort, but if the twenty patients for whom there is accommodation at Beckenham at one time, can be so benefited by treatment as to be able to once again resume the duties of life, others will take their place, and in the end the expenditure will have been fully justified. There are about six thousand ex-service men in asylums, and a large proportion of this number would have better chances of recovery, if the Sir Frederick Milner Homes could be multiplied.

NEW EDITOR FOR THE PRACTITIONER

Sir W. Arbuthnot Lane, M.S.Lond., F.R.C.S. Eng., has accepted the editorship of the *Practitioner*.

GENEVA LETTER

From our own correspondent

GENEVA, *October 10, 1924.*

THYMECTOMY

Dr. E. Bircher, of Aarau, Switzerland, a surgeon of large experience and whose opinion is always worthy of consideration, has followed the effect of thymectomy in ten children in whom tracheostenosis seemed to require the removal of large or small portions of the gland. The mental functions in these subjects were also disturbed, while it was likewise evident that bone growth was interfered with, because the appearance of the centres of ossification was delayed from two years and six months to six years. Height was interfered with only in those children who had been subjected to operation before the age of seven years. Generally speaking, Bircher's results tally with Matti's animal experiments, other than for the fact that the diaphyses in the children were practically unaffected. No changes were detected in the generative organs. Opotherapy was of no avail. Bircher is conservative in regard to operations on the thymus and believes that in stenosis of the trachea, displacement of the gland may be sufficient to overcome the condition.

HIGH BLOOD PRESSURE

There is no doubt that the old view that persistent rise of blood pressure is invariably caused by renal disease is losing ground on the Continent. Recent work by competent men has revealed the fact that there are instances of vascular hypertonus in which the kidneys are unaffected regardless of arteriosclerotic changes in other viscera, while quite marked changes in the renal vessels may be found, although high blood pressure was never noted during life. Hence, the primary character of hypertonus is a rise of arterial pressure, but whether this is the result of somatic or psychogenic factors is still a moot question. Some maintain that there is a good deal to say in favor of the rise in pressure being dependent upon vascular spasm and cases have been recorded in which this rise of blood pressure had lasted for a long time, while later on repeated examinations of the patient failed to reveal vascular hypertonus.

Quite recently, experiments were undertaken in Germany, by Kylin, to ascertain to what degree the vascular hypertension might vary in identical conditions on different days and times of day. The patients were kept in bed during all the duration of the examination—from eight to ten days—the pressure being taken between nine and ten a. m. and five to six p. m. The cases were divided into three groups: 1, socalled mild nephrosclerosis, 2, socalled diffuse acute glomerulonephritis, and 3, other affections, such as gastric disorders and neurasthenia. In the latter group, in which there was no rise of pressure, the readings varied only to the extent of ten to fifteen mm. Hg. in the course of twelve hours, and as a rule they were lower in the morning. The extent of these variations is regarded by Kylin as indicating a psychogenic vasoconstriction. In acute glomerulonephritis, which is generally the result of some acute infectious process, the blood pressure suddenly goes up accompanied by albumin, casts, and red blood cells in the urine.

I would also point out that at the Fever Hospital at Stockholm, Lindberg likewise noted that in scarlet fever the pressure began to go up about a week before the development of the renal involvement and was likewise accompanied by an increase in weight of the patient, thus indicating commencing edema. It therefore would appear that peripheral symptoms, such as increased arterial tension and edema, develop before the true renal symptoms are manifest in the urine, and it is important to note that in none of the cases of renal complications accompanied by vascular hypertonus was there any evidence of the primary morbid process started in the kidneys; on the contrary, the renal process appeared to depend upon the vascular process.

DIAGNOSIS OF DIPHTHERIA

The diagnosis of diphtheria is extremely simple or of great difficulty according to the given case, the

reason being the polymorphism of buccopharyngeal diphtheria. Any medical student can diagnose the false membranes of diphtheria, and although rather uncommon—scarlet fever being excepted—other bacteria, such as the streptococcus, pneumococcus, and tetragenus, may produce membranes on the tonsils. These anginas must be clinically distinguished from diphtheria and long ago Cadet de Gassicourt and other observers vainly attempted to confer a peculiar physiognomy upon them. They may be accompanied by enlarged lymph nodes, mucous secretions from the nostrils, etc., but they almost always respect the larynx. On the other hand, Dr. Reh has recently observed a certain number of anginas in the service of Professor D'Espine, of Geneva, which clinically were diptheria, but bacteriologically were due to the pneumococcus.

Nevertheless one must not be too quick to admit the absence of Loeffler's bacillus simply because it is not detected in the membrane or cultures. Dufourt, of Lyons, after much research work has come to the conclusion that in these socalled pseudodiphtheritic cases Loeffler's bacillus quite frequently is hidden among the varied bacterial flora found in these cases and antidiphtheritic serum will be found effective in clearing up the membranes.

FRENCH VITAL STATISTICS

It is worthy of note that the French birth rate is increasing. The returns of births, deaths, and marriages in France for last year show that the excess of births over deaths has increased.

In 1923 the excess was 94,871, or 24 in 10,000 inhabitants, as against an excess in 1922 of 70,579, or 18 in 10,000 inhabitants. The actual number of births was 761,861 in 1923, as compared with 759,846 in 1922. The birth rate in each case works out at 194 births in 10,000 of the population. In addition there were 33,591 children stillborn in 1923, as against 34,854 in the previous year. The total number of deaths in 1923 was 666,990, as compared with 689,267 in 1922. This means a reduction in the death rate from 176 in 10,000 of the population in 1922 to 170 in 10,000 last year. In 1923 the number of deaths of children less than one year old was 73,283, as against 64,889 in 1922, showing a slight increase in the rate of infant mortality. Marriages in 1923 were less numerous, being 356,501 as compared with 383,220 in 1922. These figures correspond respectively to rates of 182 marriages and 195 marriages per 10,000 of the population. There were 23,599 divorces in 1923 and 27,684 in 1922.

MORTALITY FROM OTITIS MEDIA

Out of a total of 42,000 cases of purulent otitis of the middle ear treated at the Otological Clinic at Bäle, from 1898 to 1917, there were fifty-eight deaths. The recent report from Bezold's Clinic of a total of 40,000 cases gives seventy-three deaths, a slightly larger mortality. Death from acute suppuration of the cavity of the tympanum occurs more frequently than when the process is chronic, leaving aside cholesteatomata, because the latter considerably darkens the prognosis as it causes four times more deaths than acute otitis. Otitis secondary to general diseases, such as scarlet fever, diphtheria, etc., is always serious, and the gravity, according to Schlitter, is not invariably in direct proportion to the type of causal bacteria present.

ENCEPHALITIS LETHARGICA

The excellent results obtained by Prof. Carnot and Dr. Blamontier, of Paris, in the treatment of lethargic encephalitis with intravenous injections of sodium salicylate, caused Dr. Berrien, physician to the Hospitals of Algeria, to try out this treatment in cases of typhus fever. Forty-three cases were treated with encouraging results. The injections were given every day, at the dose of from five to six grams, in a ten per cent. solution of distilled water. In this degree of dilution no instance of thrombophlebitis occurred. The injections were given until an improvement took place in the temperature and general phenomena. In some instances, when apyrexia had ensued, the administration of the sodium salt was continued *per os*. Myocarditis is a contraindication for this treatment; for this reason the heart must be carefully examined before any injection is given. If there is only slight cardiac weakness, injections of sodium salicylate may be prudently resorted to, but should be given slowly and in fractional doses, while prophylactic injections of adrenalin, camphorated oil, etc., for controlling cardiac failure are indicated. The sooner this treatment is given the less likely are progressive azotemia and terminal cardiac collapse to arise.

CEREBRAL HEMORRHAGE AND HIGH BLOOD PRESSURE

The time of life for high blood pressure—which is not invariably that of old age—is likewise that of cerebral hemorrhage. Dr. Dumas, of Lyons, has shown that high blood pressure does not alone account for cerebral hemorrhage and that encephalitis plays an important part. If high blood pressure is not sufficient to produce cerebral hemorrhage, it at least regulates the intensity and for this reason is an important factor in the prognosis. Very high blood pressure in relatively young subjects will end in fulminating apoplexy due to ventricular inundation. In older subjects with lower pressure the ictus is milder and apt to recur several times, death usually being the result of intercurrent complications and not to the cerebral hemorrhage which is small in amount. During the ictus and the days following it the blood pressure should be carefully measured. A marked drop indicates a hemorrhage of considerable amount and if the pressure does not become balanced or if it continues to drop, the patient will die in coma. If, on the contrary, the drop in pressure is slight, and if it becomes slowly reestablished without a rise of temperature, the subject will probably survive his lesion.

LETTER FROM SOUTH AFRICA

(From our own correspondent)

Pietermaritzburg, Natal, *August 16, 1924.*

TRAINED NURSES HOLD CONGRESS

At the Congress of the South African Trained Nurses' Association, held at Bloemfontein under the presidency of Miss M. G. Thomson, general president of the association, the Union Medical and Pharmacy Bill came under discussion at the second day's meeting on August 13th. Much regret was expressed

that the bill, again introduced into the Union Parliament this year, had been shelved again by the House of Assembly. The majority of the nursing delegates present expressed their support of the principle of the representation of the Trained Nurses' Association on the medical councils, and also decided upon the designation to be used in the bill in describing a nurse. A course of action was agreed upon in the event of the medical bill not being again brought before Parliament. Opinion favored a separate bill—a nurses' bill—and it was unanimously decided that in the event of the dropping of the medical bill nurses be described as registered, instead of certified as trained. The congress unanimously agreed to a resolution providing for nursing representatives on the four existing provincial medical councils.

CHILD WELFARE

The chief interest of the day's proceedings, however, was in a symposium on the child welfare movement. Instructive addresses were given on the care, training and scientific feeding of the infants and the proper training of the mothers in the course of maternity; and the congress placed a high value on the establishment of mothercraft training centres in the union. Special emphasis was laid on the plight of the country districts as regards the training of the mothers in the care of their children. Strangely enough, in South Africa infant mortality was reported to be far higher in the country districts than in the towns. This blot was to be removed, said Miss Winter (Northern Transvaal), purely through the medium of properly trained midwives.

VENEREAL PATIENTS

The congress on Thursday condemned the line of action of the probationers at the Addington Hospital, Durban, in their alleged refusal to nurse venereal disease cases. It was, however, represented by Miss Kenyon (Durban) that the probationers had not actually refused to nurse these cases, but had petitioned His Honor the Administrator of the Province in connection with the matter.

POSTGRADUATE COURSES

At the same sitting the following resolution was carried: "That postgraduate courses for nurses be arranged by the universities or hospital buildings of Capetown and Johannesburg, or elsewhere, in the hospitals attached to the medical schools."

Dr. Tremble, while supporting the idea, said that he did not see that they could have university nurses until nursing was part and parcel of a university curriculum. He suggested the taking of alternate summer and winter courses at Capetown and Johannesburg respectively, to include three lectures a week, with demonstrations and so on, and with facilities for study in special departments—the operating theatre for example—the latter being at the discretion of the matron of the hospital. The courses, suggested Dr. Tremble, should last six weeks, and the fee for attending each one six guineas for each nurse. The resolution was carried.

A PENSION FUND

The following resolution was carried: "That this association recommends that a Pension Fund for Nurses be instituted which will ensure a pension to every nurse at retiring age of £120 per annum after a complete term of service, and while not entailing a burdensome deduction from the salary of any nurse as a contribution to such fund; that provision be made for refunding at least her own contributions to the pension fund to any nurse who resigns or retires voluntarily before reaching pensionable age."

INSTRUCTIONS FOR HELSINGFORS

The congress then considered the subject of the International Conference of Nurses to be held at Helsingfors, Finland, some time next year, and at which nursing associations in all parts of the world would be represented. The delegate of the South African Trained Nurses' Association at the Helsingfors conference is to be Miss B. G. Alexander. One of the matters to be dealt with would be what is known as nonnursing duties in the training of nurses.

Miss Alexander quoted from a report published in the United States defining nursing and socalled nonnursing duties. It seemed, she declared, as if there were an effort being made to create two classes of nurse—one a sort of university student, who attended the dressings, administered hypodermics, and so on, and the other one who had to do the rough work, and attend to the ordinary functions of the body. In her opinion, there should be no work that was beneath her dignity, if she intended to do real nursing. Their duty was to give the sick public the best nursing possible. She did not agree with the two grades mentioned, and thought that the best solution of the difficulty lay in the acquirement of better pay for qualified nurses.

It was urged by members of the congress that it would be most undesirable to have two such grades as those suggested—theoretical and practical—and that if that were done it would strike at the very root of the profession. The congress instructed its delegate to take up this question at Helsingfors.

Letters to the Editor.

THE VALUE OF LIGHT

CINCINNATI, OHIO, *October 29*, 1924.

To the Editor:

The editorial on the Value of Light, which appeared in the October 15th number of the MEDICAL JOURNAL AND RECORD has just been called to my attention.

In answer to your question regarding the lamp used by Ernst, it is fair to assume, according to the figures which he states, that the spectral distribution of the light used is more nearly like that of sunlight than is that which comes from lamps commonly used in this country.

A lamp has been designed and used, which does produce a spectrum equal in extent and intensity to that of sunlight at an altitude of four thousand feet. This work has been done by Dr. Brian O'Brien, research physicist to the Buffalo Tuberculosis Association, stationed at Perrysburg, N. Y.

I trust that this fully covers the questions which you rightfully considered of importance.

R. PLATO SCHWARTZ.

Book Reviews

THERAPEUTIC SUGGESTIONS

Clinical Memoranda for General Practitioners. By A. T. Brand, M.D., and J. R. Keith, M.D., of England. Second Edition, 1924. New York: William Wood & Company, 1924.

The object of the authors in writing this book has been to gather into a small sized volume of 375 pages, including the index, very many suggestions for diagnosis and for treatment of all kinds of diseases and conditions. Obviously the aim is too general and the objects aimed at too diffuse for any author, or authors, to produce a book of much scientific value. Some of the advice given is very primary, and although the authors state that it is aimed especially to help the young physician who is commencing practice, still some of the instructions given must have been acquired by him before graduation.

The authors have placed in this book a large number of suggestions for treatment which they have obtained from medical journals and books, the majority of which treatments they have not personally studied and therefore have not carefully evaluated. They have outlined the successful results from some therapeutic measures by relating clinical histories, but the number of such cases is so small and the clinical histories are so meagre that therapeutic or statistical conclusions could not be thus arrived at.

MODERN THERAPY

Modern Methods of Treatment. By Logan Clendening, M.D., Assistant Professor of Medicine and Lecturer on Therapeutics, University of Kansas. St. Louis: C. V. Mosby Company, 1924.

The author has aimed to present a textbook that will be practical for advanced medical students. In his preface he severely criticizes available books on the subject of therapeutics. Therefore he has aimed to overcome in his book his six criticisms of available books.

The part devoted to prescription writing and methods of administration and a brief description of drugs takes up the first 150 pages.

The author's classification is not dissimilar to that offered by Osborne's book on *Principles of Therapeutics,* although somewhat more based on the action of a drug rather than on its actual therapeutic use. These classifications are much more practical than any other that can be offered.

There is an interesting presentation of the chronology of anesthesia, and the subject of anesthesia is very ably discussed.

His history of the use of digitalis is interesting, but one wonders if a book of this practical character should give so much space to historic discussion. It is better to base the action of drugs on laboratory experience rather than on historical clinical experience. The discussion of digitalis, however, is excellent.

In the discussion of drugs used to act on the respiratory tract, one must disapprove of the instillation into the glottis of a combination of menthol, iodoform, and olive oil, for chronic bronchitis or for asthma. The mild suggestion that adrenalin "may" be tried in asthma, where it is so frequently efficient, and the statement that "morphine and atropine are the surest of drugs for asthma" tend to urge too early and too careless resort to morphine in this distressing complaint.

The chapter on vaccines and serums is up to date and good. The chapter on dietetics is complete, including a long discussion on infant feeding. Also there are complete food tables.

While typhoid fever patients should be fed and not starved, the milk diets urged by some are not, in the reviewer's opinion, the best for a typhoid patient. Too much emphasis is placed on milk, and it is very generally a mistake in typhoid fever, as tending to cause tympanitis, which is the most serious thing that can happen to a typhoid patient as not only interfering with breathing and causing bowel distress, but vastly increases the danger of hemorrhage and perforation.

Part II is devoted to applied therapeutics for the various diseases. The treatment outlined is brief, of necessity in a book which is aimed to cover so much ground.

The author has certainly presented the subject of therapy in the best manner for the teaching of students. Also the book is valuable for any practitioner of medicine. A general criticism would be that he has perhaps attempted too much for one volume. When he rewrites the book he will probably enlarge it to two volumes.

FUNCTIONAL DISORDERS OF THE HEART

Les Troubles Fonctionneles du Coeur. Semiologie et Therapeutique. Par R. Lutembacher. Paris: Masson et Cie, 1924. Pp. 520.

Dr. Lutembacher has written a book on diseases of the heart from the point of view of disordered function. The clinical manifestations of disease are discussed on the basis of the underlying pathological anatomy and physiology. Such a method of presentation is valuable to the student in training him in the proper method of approach to the patient and his disorder. The first section of the book is devoted to an adequate presentation of the salient anatomical and physiological characters of the heart, and the second to a discussion of methods of examination of the heart—both clinical and instrumental. The functional disorders of the heart are grouped into two classes—those following disease of the specific conducting system and those due to myocardial insufficiency. Insufficiency of the right and left ventricles are described separately and are sharply distinguished from one another. While this has a certain validity and value, the author has gone a little too far. Ordinarily, when the heart fails, it fails as a whole, though it is true the symptoms may be preponderatingly related to one of the ventricular chambers. The inclusion of heart pains associated with cardiac insufficiency in the concept of angina pectoris is unwise and will lead to confusion.

The volume is well written and printed and liberally and intelligently illustrated. The author shows a thorough knowledge of the literature and quotes many authorities, but unfortunately gives no bibliographic references. He exhibits another failing, which is particularly common among French writers, namely, frequent careless inaccuracy in the spelling of proper names—thus "Stokes-Adams" is spelled "Stockes-Adams," "Stocks-Adams," and "Stokes Adams" on different pages.

THE OCCLUSION TEST

The Relative Position of Rest of the Eyes and the Prolonged Occlusion Test. By F. W. Marlow, M.D., M.R.C.S., Eng., F.A.C.S., Professor of Ophthalmology in the College of Medicine, Syracuse University. Illustrated with Original Diagrams and Charts, Philadelphia: F. A. Davis Company, 1924. Pp. vii-96.

Dr. Marlow has for some years past advocated prolonged occlusion of one eye for the determination of the relative position of rest of the eye in the test of muscular imbalance. His plea for a more extensive employment of this method is based on the results of seven hundred cases extending over a period of some years. This prolonged occlusion of the eye, which may last up to two weeks, while not suitable in every imbalance case, often brings to light latent conditions which elude detection by other methods of examination: in fact there are cases that show no symptoms that can be referred to disorders of ocular balance in which prolonged occlusion brings them to light: "the general condition of health of the patient, including the reserve of nervous energy with which he was endowed at birth, has a large influence beyond any doubt in determining whether a given form or degree of muscle imbalance will give rise to symptoms or not." There are, besides, many cases of muscular imbalance in which correction of refraction will, instead of ameliorating the condition, aggravate the symptoms, and it is in these cases particularly that the condition of the eye muscles must be studied most thoroughly, and the relative or anatomical position of rest of the eye accurately determined.

EFFECT OF RADIUM AND X RAYS UPON LIVING CELLS

Radium, X Rays and the Living Cell, with Physical Introduction. By Hector A. Colwell, M.B. (Lond.), D.P.H. Second Edition. Revised. London: G. Bell and Sons, Ltd., 1924.

In this work, the authors have elaborated the experimental facts which have been established as to the effects of the x rays and the rays of radium upon the living cells. An elaborate amount of study and comparison of records has been made from the literature from the first introduction of these important methods.

In Part I, the transmission of both x rays and radium, and the ionization produced are fully considered, together with other radioactive substances and the general process of radioactivity. The disintegration of radioactivity and the radioactive emanations and the occurrence of radium in nature are well considered. In Part II, the chemical action on the forms of animal life, seeds, plants and bacteria are considered. The effects on the skin, blood, bloodvessels, spleen, thymus, thyroid, digestive tract, glands and the nervous system are each treated with compared results and the consideration of experimental studies that have been made by numerous authors with illustrations showing the relative effects. Then the consideration of the various complex studies of the body, including the eyes, muscle, cartilage, and connective tissues and the generative system are given the careful consideration of the authors and their numerous collaborators.

In the concluding chapters of the book, the authors have considered the effects upon malignant cells and shown the microscopic studies of sections in this connection. The production of malignant disease has also been given careful consideration. Idiosyncrasy and dosage and the physiological effects, and the selective and differential action of the rays, and the brief summaries of the facts and theories complete the work.

The preparation of this work shows an elaborate study of the literature since the beginning of the use of these measures. A bibliography follows each chapter which renders invaluable the work as a book of reference to the students of the x ray and radium.

The manufacture of the work is remarkably good and the illustrations are clear and invaluable in consideration of the subject. It is a reference book which physicians will value highly as showing the fullest consideration up to date, we believe, with advanced opinions of the subject.

THE TUBERCLE BACILLUS

Le Bacteria de la Tuberculosis. By Joaquin Ravetllat and R. Pla Y Armengol. Barcelona: Institutio Ravetllat-Pla, 1924. Pp. 75.

This interesting book has been issued by *Publicaciones del Instituto Ravetllat-Pla* in Barcelona and is the work of a distinguished veterinarian, Joaquin Ravetllat, and Dr. R. Pla y Armengol. It is written in correct Spanish, but fortunately for one who is not familiar with that language, there appears at the end a synopsis in English.

The authors have studied the tubercle bacillus in a unique manner which has led them to the conclusion that there exist three forms of the human type of this microorganism. They speak of a bacterium of attack, the intermediate bacterium or transition form, and the Koch bacillus or resistance form. The bacterium of attack the authors describe as a coccus which, "when it proceeds from cultures in liquid mediums presents itself isolated, in diplococcus, short chain or diploestreptococcus, tetradas and zooglea, the diplococcus predominating. In cultures in solid mediums it presents itself almost always in diplococcus or diploestreptococcus. It is slightly mobile. It colors well by means of all the basic analine dyes. It is not acid resisting. When it proceeds directly from the Koch bacillus it is gram positive; when it proceeds from the other attacking bacterium in series it is also gram positive." The manner of culture of this type of bacterium is then given. The virulence of this bacterium is considered variable from the highest most severe type to almost zero. The action of the microorganisms in the various internal organs

in the guineapig, rabbit and dog is given. "In all the animals, from the day following that of the injection (in whatever place it was made) the bacterium is found to be present in the blood . In the guineapig it does not disappear, and in the other animals it persists a long time in spite of their healthy aspect. The reinoculations determine often the formation of abscesses with pus similar to the caseum, and in the guineapig and rabbit in certain cases, the formation of tubercles."

In the intermediate bacterium, or transitory form, the authors include the germinative phase of the Koch bacillus in the cultures, the Much granules, and the intracellular corpuscles of the caseum and of some tuberculous serosities. The Koch bacillus the authors describe as the "bacillus of resisting form." In this chapter the authors give the usual characteristics and conclude with the following statement: "For us the Koch bacillus is a union of the attacking bacteria (coccus, granule, or nucleus) which, by the action of the organic defenses whether or not they pass through the intermediate form (another coccus or granule) dispose themselves in a short chain, and, besides modifying their interior constitution, cover themselves with a very protective wax capsule. If this is the case the intuition of Koch turns out to be admirable when he said 'each one of the isolated spores correspond to a fragment of bacillus so that on counting them one knows how many fragments enter into the composition of the bacillus, that is to say, how many isolated elements enter into its formation.' These elements would be, according to our view, attacking bacteria."

This work, which is illustrated by very good plates, must be of greatest interest to laboratory workers and if the conclusions at which Ravetllat and Armengol have arrived can be confirmed by other research workers, the work may prove of great clinical value.

CORRECT POSTURE

Individual Gymnastics. A Handbook of Corrective and Remedial Gymnastics. By Lillian Curtis Drew. Second edition, thoroughly revised. Illustrated with 109 engravings. Philadelphia and New York: Lea & Febiger, 1923. Pp. viii, 260.

This book is a useful one in its field, presenting many practical facts as to the training and correcting of the body in regard to its physical postures. It shows that this field is no small one either in the range of details to be considered or in those to whom it makes its appeal. These are special teachers of gymnastics who must be alert toward the individual problems which are constantly present. They are parents who in lamentable ignorance and habitual carelessness fail to observe errors of posture, of dress and other factors the results of which they deplore and which this book calls plainly to their attention. The writer sets forth these facts which show the need of physical training and the means by which this may be secured on the basis of her own practical experience in this work. Her writing is well illustrated with drawings which plainly emphasize the work to be done and reveal how it may be done. The subject is important and is made practicable by its presentation here.

It might, however, make too arbitrary an appeal if one did not remember that this matter of physical training is only one of the methods which must be conjoined with much else for a complete adaptation to the demands of life. Correct postures are an aid to this but at the same time they are a result, too, of an attitude toward life which admits of freedom and therefore of the most efficient action of the entire being, physical and mental. No wise teacher of gymnastics would deny this larger background, but such a view needs emphasis in a book which presents the physical side so well as is done here.

DELUSIONS OF GRANDEUR

The Memoirs of Li Hung Chang. By W. F. Mannix. With an introduction by Ralph D. Paine. New York: Houghton Mifflin Company, 1923.

In the introduction to the new edition of these controversial memoirs, Ralph D. Paine gives the history of the author. A man of brilliance, but lacking stability, he showed numerous neurotic traits, the least among which, perhaps, was the tendency to the drug habit. After a lifetime of shirking responsibility, hoaxing himself and everyone else, it is not to be wondered that in the seclusion of the Honolulu jail his disease finds at last a perfect outlet. He creates the life of a well known man. He sinks himself into that life as he creates it. Ergo—he *is* that well known man. Who better than he could write the memoirs?

The press clipping history of Chinese affairs is cleverly disguised. There is show of much meat and after all there is very little. It is the man, always the man, with his victories outweighing his defeats, around whom the story revolves.

Li Hung Chang's *alter ego* has a manner of expressing himself which will prove diagnostic to the medical reader. The physician finds constant wonders in the brain of man, no matter how diseased or unbalanced it may be. As a textbook of mental deterioration the memoirs are almost as valuable as for themselves. And twice as interesting!

ADVENTURES IN THE ARCTIC REGION

Wilfred Grenfell, the Master Mariner: A Life of Adventure on Sea and Ice. Illustrated. By Basil Mathews. New York: George H. Doran Company, 1924. Pp. 178.

This narrative of a life most unusual for a physician has been given color and vividness by the fact that the author visited Dr. Grenfell's boyhood school and heard told and read tales written by the noted expupil about his exploits for boys of later generations. In fact Mr. Mathew's book is evidently written for the information of young people as to the life and career of the missionary physician in Labrador, judging from his choice of material and his treatment of the subject. The story is in places carelessly told as to style, but it is always vivid and interesting. No new material of importance is added to that included in former biographies, for some of the most characteristic incidents only of the full life of Dr. Grenfell have been selected and briefly yet graphically related. The chief value of the book lies in its appealing presentation of the character and personality of the Labrador doctor in such a way that not only can youth fail to be interested in such a man and such a career, but people of any age who believe in a life of service to humanity.

Medicoliterary Notes.

The *Living Age* for October 11th contains two interesting contributions on the history of smoking and the tobacco habit. The first is an abstract of an article by John Fortescue in the London *Morning Post* tracing the history of the cigarette habit in Great Britain, from the introduction of the cigarette in 1877, until its complete popularization after the Egyptian campaign in 1882. The second article is called Pipes and Politics and is a translation from *L'Ere Nouvelle* of Paris. "Historicus," the writer, outlines most amusingly the role played in his conception in politics by the practice of smoking and snuff dipping, from the time when Nicot's plant from the Island of Tobago was first introduced into Europe, to a final salutation of the pipes of Herriot and MacDonald, "for they have won a standing undreamed of even during the bright dawn of liberty in 1830."

* * *

Louisiana's recent move to accept the provisions of the Federal Maternity and Infancy Act makes the total number of states now cooperating with the Government in this form of welfare work forty-one.

* * *

The New School for Social Research of New York City has been giving to its students four courses in practical psychology. These are the Technic of Influencing Human Behavior, by Dr. Harry A. Overstreet, professor of philosophy at City College; Behavior Psychology, by Dr. John B. Watson; Introduction to Social Psychology, by Dr. Everett Dean Martin, director of the People's Institute of New York City; and Personality Development, by Dr. William I. Thomas, author of Social Origins and of many monographs and articles on social science.

* * *

Yellow is now considered the best color with which to decorate hospital walls and corridors, according to M. Paul Rea in a recent issue of the *Modern Hospital*. It supplies warmth to the eye and a certain sense of stimulation to the mind, and, properly toned, is of so unobstrusive a character that it is not easy for the patient to recall the color after leaving the hospital. When deepened to tan, it retains its pleasing character and at the same time shows soil and marring less, so is especially suited for the walls of diet kitchens, laundries, and other service and work rooms.

* * *

Some interesting chapter headings in Benedetto Croce's recently published *Conduct of Life* are Responsibility, Sex, Humility, the Joy of Evil, Heart, and Reason.

* * *

All good Englishmen are up on their ears over a recent move of the socalled Church of the Universal Bond. This is the official name of a group of modern Druids who have horrified the editorial pages of the London *Times* by securing permission to bury the ashes of their dead in Stonehenge.—*Living Age.*

* * *

Nightshade is the title of a recent novel which should be of unusual interest to the psychoanalyst. The work is anonymous and purports to be the story of a young lawyer in one of America's small towns, and of his reactions to the life of such a community. The style is simple yet vivid and the story is convincing.

* * *

The Atlantic Monthly Press has announced that the letters of William James have recently been translated into French, with a preface by Henri Bergson. Another work in English to be put into a new French edition is the Late Joseph Conrad's *Nigger of the Narcissus*. Robert Humière, who translated many of Kipling's books, is the translator.

* * *

George Sand was an inveterate smoker and collector of pipes. She once said, "He who does not smoke is not a whole man."

* * *

There are four present day writers who have performed the difficult and unusual feat of winning their literary spurs in an acquired language. They are Joseph Conrad (alas! no longer with us), W. L. George, Edwin Bjorkman, and Gunnar Gunnarsson. Conrad, a Pole, after years as a sailor before the mast, mastered the English language and became, perhaps, the greatest stylist of the present age. W. L. George was born in France and lived there until he reached man's estate. He did not succeed in leaving the French language behind when he crossed the Channel. His conversation is still gluttonous with it, not to mention his writings. Edwin Bjorkman was born and brought up in Stockholm, Sweden, but has been a citizen of the United States for over thirty years. On coming to this country he knew little more than schoolboy English and yet his first published story in English appeared in the *Atlantic Monthly*. The last of the quartet, Gunnar Gunnarsson, although he writes in Danish, was born and brought up in Iceland.—*Literary Review.*

* * *

The October issue of the *Survey Graphic* contains a review of the Leopold-Loeb trial written by George W. Kirchwey, former warden of Sing Sing Prison.

* * *

The production in Spain of Luigi Pirandellois *Six Characters in Search of an Author,* which had a successful run in New York theatres in 1923, is reported to have stirred up a tremendous press battle in that country which persisted for several months. While the fight was on, every Spanish press writer was lined up, either pro or con.

* * *

McNaught's Monthly for September contains an article by Dr. Joseph Collins, author of *The Doctor Looks at Literature* and other works, on *Our Moral Imbeciles,* which takes as a text the Franks murder trial.

* * *

Tobacco dealers report that for several years the "snuff curve" has been rising rapidly on the charts made by statisticians for the trade, so that it looks as though snuff dipping is again about to become popular. Some attribute this increase to the general increase in use of tobacco of all kinds. Others lay it to the younger generation of today, ever in search of new thrills. Now it is seldom taken nasally, but, the dealers say, placed on the tip of the tongue or rubbed just back of the teeth. To sneeze is very bad form. Only the very young and inexperienced are guilty of such a *faux pas.*

* * *

A social survey of the town of Ipswich, England, which has a population of 80,000 people, indicates that the waterworks supply 8,250 gallons of water a year per capita to its citizens, but there are church accommodations for only one person out of three. Despite the housing shortage, the people are better lodged in respect to both roominess and the quality of tenements than a century or more ago. The number of individuals per dwelling has declined since 1801 from five to four and four tenths.—*Living Age.*

* * *

The University of Missouri, in cooperation with the U. S. Bureau of Mines, is offering a fellowship in industrial hygiene, which is open to graduates who have a B.S. degree in public health or the equivalent or a B.A. degree in arts and sciences or the equivalent and an M.D., and have the proper training in biochemistry, pathology, and physics, and who have the qualifications for research work. The work will be conducted in the Department of Hygiene of the university's School of Mines and Metallurgy.

* * *

Two bulletins of unusual interest to industrial hygienists are Numbers 355 and 359 of the Bureau of Labor Statistics of the U. S. Department of Labor, reporting the proceedings respectively of the International Association of Public Employment Services, held at Toronto, September, 1923, and of the International Association of Industrial Accident Boards and Commissions, held at St. Paul during the same month. Another recent noteworthy government publication is *Public Health Bulletin* No. 139, reporting the transactions of the annual conference of the State and Territorial Health Officers with the U. S. Public Health Service, held at Washington in May, 1923.

* * *

Louder Please! The Autobiography of a Deaf Man, is the arresting title of a rather unusual autobiography. Earnest Elmo Calkins is the author, and he tells the story entertainingly, with humor, and with occasional pathos of his rise from a pessimist to an optimist, and, incidentally, to a high position in the advertising world.

Abstracts from Current Literature

ENDOCRINOLOGY

Familial Dysthyroidism.—G. Etienne and G. Richard (*Revue Française d'Endocrinologie,* February, 1924) report a case of severe Basedow's disease in transformable vagotonic form. There was a thyroid family history attached to eight of the nine individuals in three generations, the ninth person being a syphilitic grandfather. When the patient, a girl twenty years of age, came under observation she was in an advanced cardioneurotic condition, with pronounced exophthalmos. Large doses of thyroid extract administered over a period of several months brought her to an approximately normal condition. About three years later she lapsed into a state of evident myxedema, which was again relieved by pushing the thyroid treatment.

Effects of Testicular Grafts in Senile Organisms.—C. J. Parhon and M. Kahane (*Revue Française d'Endocrinologie,* February, 1914) observed transient socalled rejuvenation in a man of seventy-eight and in a dog sixteen years old following the implantation of testicles from young and vigorous subjects. The authors discuss the relation of the various endocrine glands to old age, and close by proposing for further study the following three questions: 1. In what measure the symptomatic picture of old age is due to disturbance of the endocrine functions; 2, Whether old age can be experimentally produced by means of endocrine intervention, and 3, to what extent experimental or natural old age can be remedied by organotherapeutic treatment, grafts, or other intervention of the glandular system.

Testicular Grafts.—Kenneth M. Walker (*Lancet,* February 16, 1924) used fragments of ectopic testicles, obtained from young donors between the ages of ten and twenty-two showing well developed sex characters, for implantation into the tunica vaginalis in cases of testicular deficiency. Tuberculosis, malaria and all other constitutional disorders must be excluded in the donors. In a number of cases metabolic investigations showed a marked increase in oxygen consumption to the square metre of surface after the implantation and a greater capacity for work. While the results appear very promising, this operation has its limitations aside from the difficulty of obtaining the grafts. In few of the cases is the deficiency confined to the testicle and many show other endocrine deficiencies. All heterografts, no matter how complete their vascularization, undergo absorption, but the patient does not necessarily show the same degree of deficiency as before the operation. It may be possible to improve considerably a boy showing signs of eunuchoidism during puberty, even though the transplant may subsequently be absorbed.

Steinach's Rejuvenation Operations. — Kenneth M. Walker and J. A. Lumsden Cook (*Lancet,* February 2, 1924) conclude that at the present time there is insufficient material on which to base a decision as to the value of vasoligature as a means of treatment in man. The results of the operation appear to have been capricious, although numerous cases are reported in which benefits accrued. As, however, the data on which the claims of improvement rest are inexact and incapable of measurement, a large number of observations will be necessary before it will be possible to bring in a final verdict as to the precise value of this form of treatment. However, whatever the verdict concerning this clinical problem may be the results obtained by Steinach in his animal experiment are certainly of the greatest biological interest.

The Behavior of the Testis in Transplantation.—Carl R. Moore (*Endocrinology,* July, 1924), experimenting in the Hull Zoological Laboratory at the University of Chicago, discovered that testicular grafts uniformly failed under any other conditions, but persisted and continued to function, if implanted within the tunica vaginalis. Absence of function in cryptorchidism and similar conditions he believes due to pressure, whether from retention in an obstructed canal or otherwise. The interstitial tissue under such circumstances is not overdeveloped and not different from that of the normal testis, but the germinal cells fail to differentiate completely. Even in the guineapig, rat, rabbit, and other animals, which throughout life retain a wide open connection between the scrotum and the peritoneal cavity, the germinal cells are degenerate so long as the testis remains in the peritoneal cavity. The scrotum seems therefore to exert a striking influence on the testis. Removed from the scrotum, a testis is rapidly deprived of its germinal epithelium. The socalled Steinach operation the author ascertained to cause no degeneration, provided the testes retain their normal scrotal relationship, and therefore not to be the cause of the rejuvenation attributed to it. His experiments further tend to show that it is the higher temperature of the peritoneal cavity which causes degeneration of the germinal cells in retained testicles. He asserts that the scrotum of mammals is to be considered a local thermoregulator for the testes and that the regulatory or functional capacities are indispensable for the production of differentiated germ cells or the maintenance of those already produced.

A Quantitative Study of the Human Hypophysis Cerebri or Pituitary Body.—A. T. Rasmussen (*Endocrinology,* July, 1924) made accurate weight measurements of several parts of the normal gland in fifty adult males and found the average somewhat smaller than other authors have done. The pars anterior represents about seventy-two per cent. of the total organ, pars nervosa eighteen per cent., pars intermedia two per cent., capsule eight per cent. Three additional cases having typical symptoms of postadolescent hypopituitarism were well within normal limits as to weight of the whole organ and of its various parts.

Heteroactivity of the Pituitary Gland with Hyperthyroidism.—C. M. Wilhelmj (*Endocrinology,* July, 1924) records a very complete history and examination of a case and discusses the differential diagnosis and etiology. He regards it as an instance where the patient suffered from hyperfunction of the anterior pituitary lobe before puberty, the condition changing at that time to hyposecretion of the posterior lobe with a moderate degree of hyperthyroidism. Oral administration of large doses of whole pituitary extract with injection of pituitrin gradually afforded relief, but the medication required to be continued permanently.

Glaucoma and Other Eye Conditions Due to Endocrine Disturbances.—J. Imre (*Klinische Wochenschrift,* July 15, 1924) regards his experiments as pointing directly to a connection between glaucoma and endocrine function, generally of more than one gland. Hertel has shown that the hypertension of glaucoma in association with hypothyroidism is reduced by thyroid treatment. Ovarian hypofunction occurred in four cases of keratoconus, and hypothyroidism in one case, all of them being benefited by glandular medication.

Endocrine Therapy.—A. E. Gow (*British Medical Journal,* April 19, 1924) maintains that most of the endocrine preparations now in use have no therapeutic value when given by mouth. As a rule, tissue extracts for intravenous use show approximately the same effect as foreign proteins, and with few exceptions, show no specific action. With the exception of thyroid and parathyroid gland, no other extract is absorbed as such from the digestive tract. Epinephrine has been found valuable in shock, asthma and other spasmodic conditions such as cardiospasm, urticaria and angioneurotic edema. Pituitary extract is useful as a stimulant to a failing myocardium, especially in toxic myocarditis and in the third stage of labor. The author is particularly opposed to shot gun prescriptions of endocrine glands in the hope that one of them will hit the mark.

Relationships of Myxedema to Immunity.—G. Marinesco (*Bulletin de l'Académie de médicine,* May 27, 1924) dissents from Conland's view that reduced thyroid activity necessarily implies greater resistance to tuberculous infection, and refers to Garibaldi's conclusion that thyroid insufficiency may cause either an increase or a decrease, or have no effect on, the resistance to infections according to the experimental conditions, the results from thyroidectomy in this respect varying with the dose, toxicity and physical state of the septic products injected, the duration of the inoculations and the time elapsing between thyroidectomy and inoculation; large amounts of highly toxic or virulent and very diffusible septic products, vis., toxins, seem to be the cause of the lowered resistance of thyroidectomized animals. The author reports two cases of con-

genital myxedema illustrating the low degree of resistance of such patients to infections in general. The first was a myxedematous idiot thirteen years old, who contracted erysipelas twice and later measles, the latter followed by irregular fever continuing for nearly seven months, until the child's death, with pulmonary tuberculosis, diarrhea, loss of weight, prostration and somnolence. In the earlier infections, fever had never been high, doubtless owing to the absence of the thyroid—demonstrated at the autopsy—this gland playing an important role in the acceleration of oxidation and in rises of temperature. The cells of the cerebral cortex were found of subnormal size and the cortex thinned. The nerve cells elsewhere, including those of the spinal cord, showed a similar deficiency. Association fibres showed poor development. The tuberculous foci showed an unusually dense pullulation of the tubercle bacilli. The islets of Langerhans and pancreatic cells, the adrenals, and the renal glomeruli and convoluted tubules were all reduced in size. The same applied to the striped muscle cells, though interspersed with the latter were a few fibres having two or three times the diameter of normal muscle fibres. Within the sarcolemma was an abnormal mass staining with hematoxylin and thionin. The other case of congenital myxedema died at the age of thirty-six years from epidemic influenza with intestinal disturbances. The thyroid was absent, being replaced by two small colloid cysts, and the liver, pancreas, kidneys, ovaries and even the pituitary and brain contained streptococci—a finding ascribed to lowered resistance to infection. The influence of the thyroid in the defence against infections is probably not a direct one, as it is not the thyroid that secretes antibodies but an indirect one relating to impaired body nutrition and development, since the thyroid governs the metabolism of the organs which manufacture the substances antagonizing infections.

Splenic Endocrinism and Pancreatic Exocrinism.—M. R. Castex, of Buenos Aires (*Revue Française d'Endocrinologie,* April, 1924) relates two cases which he says incontestably prove the existence of a splenopancreatic interglandular correlation, splenic endocrinism taking part in pancreatic exocrinism. In one of the patients, examination of whose feces showed intense creatorrhea resulting from insufficiency of the tryptic secretion of the pancreas, he twice obtained a disappearance of the creatorrhea, or in other words a normalizing of the tryptic secretion, by means of splenic organotherapy, while this tryptic insufficiency reappeared on discontinuing the splenic extract. In his opinion these two clinical observations, both of them in cases of exocrine pancreatic insufficiency of especial severity as regards the secretion of trypsin, both of them on subjects having considerable splenomegaly from a similar etiology of paludism, syphilis, and alcoholism, both of them uniformly responsive to splenic organotherapy in the matter of the tryptic insufficiency, demonstrate a participation of a decisive nature on the part of the spleen in the exocrine function of the pancreas.

Adrenal Virilism Complicated by Diabetes Insipidus.—A. Chauffard (*Revue Française d'Endocrinologie,* February, 1924) describes the case of a woman of forty whose menstruation had ceased three months earlier without possibility of pregnancy. At the same time hair appeared all over her body. A scanty black beard of half an inch or more covered her face, its hairs forming a thin, tangled network; black tufts filled the axillæ and a veritable forest of black hair covered all the pubic region. The limbs, thighs, abdomen, back, arms and forearms presented a thick mat of black hairs. Her face was congested, its aspect decidedly masculine although her voice was unchanged; her mental activity was diminished by a sort of cerebral hebetude. A swelling in her right side was diagnosed as a benign adrenal tumor and was subjected to ten applications of deep radiotherapy. An immediate local improvement was produced, the tumor diminished by half, her strength being regained, and psychic activity returning. But her face remained congested and the hypertrichosis unmodified. After a few days she was attacked by intense thirst, marked polyuria, and the other symptoms of diabetes insipidus. This improved under pituitary extract, but the patient died shortly afterward of pulmonary congestion. The initial malady was the genitoadrenal syndrome of Gallais, and the endocrine condition was a pluriglandular one. an ovarian involvement being shown by suppression of menstruation and a pituitary by diabetes.

Importance of the Internal Secretions in Various Forms of Cataract. — Adler (*Klinische Wochenschrift,* July 22, 1924) discusses the etiology of different forms of cataract. That of Basedow's disease he ascribes to the pressure of the enlarged gland on the parathyroids. Glassblower's cataract has a somewhat similar origin. The heat or the excess light from the glowing mass leads to the presence of methylguanidin and other toxic substances in the blood, instead of being fixed by the parathyroids. The resulting latent tetany is manifested in cataract. Two and a half years after raying of a mammary carcinoma with the röntgen ray the author witnessed clouding of the lens. Chvostek's sign and Trousseau's were absent, but the electrical response was increased, especially in the median and ulnar nerves. Careful examination, he says, will often detect evidence of latent tetany in those having cataracts, and senile cataract may frequently be ascribed to lesions of the parathyroid bodies.

Postoperative Myxedema.—E. Bonilla and C. Blanco Soler (*Endocrinology,* March, 1924) report a case of this condition. The patient was first seen after the removal by operation of the right lobule of the thyroid, the isthmus, and all the left lobule except the posterior border. His symptoms were frequent and sometimes severe diarrhea, nervous dyspnea, tachycardia, tremor of the hands and tongue, exophthalmos, cephalalgia, insomnia, light melanoderma, buccal pigmentation, asthenia, sexual frigidity, and intense melancholy with fear of being alone and tendency to suicide. Intensive thyroid treatment, six half grain tablets daily, was begun and produced great improvement in a month's time. On reduced doses he progressed steadily to complete cure, the exophthalmos and the psychic disturbances having absolutely disappeared. The authors conclude that, except in cases of compression, cardiac alterations, or other disorders in which social conditions act as impediments, hyperthyroidism ought always to be treated medically. Partial extirpation of the gland scarcely ever cures. In this patient exophthalmos persisted after thyroidectomy and resection of the sympathetic and he was completely cured by thyroid treatment.

Mitochondria Content of the Thyroid as an Index of the Activity of the Gland.—William Bolt (*Journal of Laboratory and Clinical Medicine,* June, 1924) used a method practically identical with the Cowdry modification of the Altman-Bensley stain for the study of mitochondria. In exophthalmic goitre in operative cases the mitochondria were found to be largely and uniformly increased, the cytoplasm being infiltrated by a dense mass of small red granules, except in one instance, where they were much less numerous. The adenomata also showed a marked increase in mitochondria, but not uniformly so, as in the exophthalmic cases, the increase being more marked in some areas so as to give the section a mottled appearance. In colloid goitres with toxic symptoms the examination for mitochondria may reveal changes otherwise undetected, for although in most of the cases there was some hyperplasia, in all the cases examined the mitochondria were markedly and generally increased. The findings in these cases correspond with the results obtained by Goetsch.

Individual Constitution and Endocrine Glands.—Julius Bauer of Vienna University argues (*Endocrinology,* May, 1924, 8:297) from the investigations of Morgan in the field of heredity that the chromosomes, probably twelve in number, represent the totality of transmissible qualities, which are localized in some way in these little bodies. During the evolution of the whole organism from a single fertilized ovum a part of every one of these chromosomes enters every new body cell. The specific structure of the chromosomes is responsible for the characterization of the species, race, family, sex, and a great many of the individual peculiarities potentially determined and fixed at the moment of fertilization. The units for body length manifest themselves in the cells of epiphyseal cartilages, the units for a long nose in the cells forming later the constituents of the nose, the units for musical talents in certain brain cells, and the units for red hair in the cells producing the hair pigment.

In correlation with this chromosomal potency stands also hormonal potency, as interpreted by the author, intensifying or checking the action of the former. Secondary sex characteristics, for instance, are associated with the primary, not only through the hormonal influence of the glands, but

through chromosomal correlation. Every cell of the organism obtains its definite sex peculiarity from the moment of fertilization of the ovum, and a certain chromosomal structure is responsible for the sex in every one of the body cells. Of course a sexual difference will not be manifest in the cells of the liver or of the lungs, but it will be quite obvious in the cells that produce the hair, those that form the breasts, and so forth.

In the same way the interference of chromosomal and endocrine effects is to be considered in the problem of fat deposition, of evolution and of senile involution of the organism, and in many other problems. Everywhere we meet with the endocrine organs as a sort of multiplier and condenser of certain chromosomal potencies. Not everything which is attributed today to pure endocrine disturbance is in reality of endocrine origin. The interference of general chromosomal, that is of constitutional, and of incretory influences must be taken into consideration in a great number of cases where up to date unsatisfying hypothetical suppositions of pure hormonal disturbance have been suggested.

Recklinghausen's Disease.—P. G. Castellino (*Folia Medica,* No. 11, 1924) describes the case of a man of sixty having more than four thousand fibrous tumors invading practically every structure of his body, many of them of considerable size. He quotes Révillod, Chauffard, Branca, Breton, Suzuki, Vignolo-Lutati, Preiser, Bosquet, and Muto as reporting cases accompanied by endocrine pathology, disclosed at autopsy, mostly adrenal or including adrenal degeneration. Taking these reports into account, together with the success of organotherapy in other cases, he says, Muto, Pende, Castellino, Lyon, and others think Recklinghausen's disease should be considered a disturbance of several endocrine glands manifesting itself through the sympathetic system by the formation of fibrous tumors. Muto says it "originates from some constitutional or acquired factor, such as tuberculosis, infection, or trauma, which leads to an alteration in the body metabolism, and creating the conditions necessary for the development of embryonal cells in the skin and nerves."

Relation of the Thymus to the Venous Trunks at the Base of the Brain.—M. Lucien and J. Guibal (*Revue Française d'Endocrinologie,* April, 1924) state that in exceptional instances examination of fetuses and of infants expiring at birth showed that the left innominate vein passes in front of, instead of behind the thymus gland. In such instances compression of the vein between the thymus gland and the sternum from flexion of the head during birth or from other cause may well produce such an asphyxia and general venous stasis as to account for death. Such a compression produces among its effects an engorgement of the veins in the thymus gland itself, and this stasis progressively increases the size of the gland and the compression of the vessels at the base of the neck, thus constituting a vicious circle of vascular engorgement.

CARDIOVASCULAR DISORDERS

Arteriosclerosis. — William Russell (*British Medical Journal,* May 17, 1924) maintains that the raising of aortic pressure results from constriction of the arterial wall and consequent diminution of the content of blood in the constricted arteries. The true blood pressure is determined by the response of the left heart to the increased aortic pressure and the left heart may become embarrassed and commence to fail, so that the arteries may be constricted without elevation of the blood pressure. The arterial constriction is attributed to the composition of the blood—and acidosis. Frequently the application of the doctrine of acidosis is effective in some of the clinical manifestations of arterial hypertonia, both when the arteries are sclerosed and when they are normal. Whatever the precise nature of the blood impurity, it is more than a vasoconstrictor, for it leads to obliterative endarteritis in the kidneys and to capillary occlusion.

Angina Pectoris and the Possibilities of Its Surgical Relief.—K. F. Wenckebach (*British Medical Journal,* May 10, 1924) subscribes to the theory of Allbutt and favors the treatment of angina pectoris by resection of the depressor nerve. However, it is doubtful whether this operation will ever be the operation of choice because of the difficult and sometimes impossibility of finding this nerve. On theoretical grounds it is the safest form of procedure because only afferent nerves are removed and the essential augmentory nerves are left intact. It has been shown that the depressor nerve, when the aortic wall is stretched as a result of high blood pressure, results in a rapid fall of the blood pressure, thereby relieving the stress on the aortic wall.

Syphilis in Angina Pectoris.—L. Gallavardin (*Presse médicale,* July 16, 1924) presents a statistical study on 450 cases of angina pectoris, comprising only cases in which the pain was felt on exertion. The series as a whole showed twenty-one per cent. of cases of known syphilis and nine per cent. of cases of doubtful syphilis. Subdivision of the cases into certain groupings showed that among cases of angina pectoris attended with aortic lesions a syphilitic history is extremely common. In angina on exertion combined with aortic insufficiency, syphilis—known or doubtful—is almost the rule (eighty-eight per cent.), and in cases combined with aortic aneurysm is constantly present. In angina without an aortic lesion, the frequency of syphilis drops to about twenty per cent. The younger the patient, the greater the frequency of syphilis—forty-four per cent. below forty years, as against 17 per cent. above fifty years. In angina superimposed on dyspnea on exertion in cases of high blood pressure, the frequency of syphilis drops to fourteen per cent. Thus the consideration of angina on exertion as uniformly an indication of syphilis is unjustified.

Syphilitic Aortitis.—H. B. Haskell (*Northwest Medicine,* August, 1924) asks what may be expected from treatment in this disease and gives the following answer: 1. In simple aortitis an arrest of the process and prevention of aortic incompetence and aneurysm. 2. In cases of suffering from paroxysmal dyspnea and anginalike pain, we may expect relief from the attacks in a certain number of the cases over a varying period of time. 3. In aortic insufficiency and aneurysm we cannot expect very much. We cannot hope to undo the damage already done, but it is our duty to treat the syphilis in the hope that we may arrest further progress of the disease.

Tinnitus Aurium Associated with Abnormalities of Blood Pressure.—H. Mortimer Wharry (*Lancet,* May 3, 1924) draws the following conclusions from his series of cases: 1. That cases of severe tinnitus aurium with abnormal blood pressure form a large and important group in which much distress can be relieved. 2. That severe tinnitus aurium may be due to a high blood pressure alone or to a low blood pressure alone, in which case it is usually found to be bilateral. 3. That it may be due to an aural lesion combined with a high blood pressure, or with a low blood pressure, in which case the tinnitus is on the side of the lesion. 4. That in the circumstances just mentioned the tinnitus may be cured or improved by removing the aural lesion alone, or by reducing the blood pressure to approximately normal, or by doing both. 5. That trinitrin is of great value as a therapeutic agent in the cases associated with a high blood pressure, as it appears to have a specific effect in relieving the tinnitus.

Blood Pressure and Sugar Metabolism.—In studying fifty nondiabetic patients with hypertension J. Koopman (*Endocrinology,* May, 1924) found hyperglycemia to be only an exceptional occurrence, as were increase of uric acid in the blood and alimentary glycosuria. From estimation of blood pressure in 161 cases of diabetes it was seen that in young diabetics blood pressure was normal, while in older patients hypertension was the rule. No relation was found between complications and blood pressure, excepting Bright's disease and arteriosclerosis. Acidosis does not cause a diminished blood pressure.

Capillary Pulsation, with Special Reference to Nasodilatation in Aortic Regurgitation. — Thomas Lewis (*British Medical Journal,* April 26, 1924) summarizes his findings as follows:

1. When human skin is soaked in water at temperatures of 45° to 47° C., the capillaries and venules on the one hand, and the arterioles on the other, independently dilate. These are both local reactions. When higher temperatures are used, a reflex dilatation of the arterioles is observed in addition, and this spreads beyond the heated area.

2. Capillary pulsation is a physiological phenomenon, occurring in the skin or mucous membrane whenever the arterioles are sufficiently dilated, providing that the pulse pressure is normal and capillary and venule tone is not increased. A sufficient dilatation to produce pulsation is

usual in the arterioles of the face of young people at room temperatures. Pulsation occurs in the water providing the arterioles are capable of dilating; it is usual in association with the vasodilatation of local inflammatory lesions; it occurs in the facial flush of amyl nitrite, and in the other forms of bright erythemas of the skin.

3. If, in the presence of normal or heightened pulse pressures, capillary pulsation in the hand is not produced by this water test at the end of three minutes, the arterioles are probably incapable of dilating.

4. In aortic regurgitation, capillary pulsation is often independent of high pulse pressure, although the latter increases the pulsation. In patients with valvular defect, sufficient dilatation of the arterioles is again the chief determining cause of capillary pulsation. The state of the arterioles not only chiefly determines its presence or absence, but *a fortiori* it determines its varying prominence in different skin areas.

5. The color of the facial skin in uncomplicated aortic regurgitation is not pale, as usually stated, but, if anything, more flushed and warm than normal. The skin of the hands is affected like the face, but in a lesser degree.

6. Arteriolar dilatation is opposed to cyanosis.

7. It is more accurate to associate capillary pulsation with dilated arterioles than it is to associate it exclusively with any other causative factor; and this statement is independent of the clinical diagnosis of the case.

8. It is probable that in all cases of macroscopic capillary pulsation the phenomenon is due to the pulse passing from the arteries into and through the capillaries, to involve in greater or lesser degree the minute skin venules. The visible pulsation is shown to be due mainly to pulsation of the venules, at all events in the skin of the face, trunk, and upper parts of the limbs. Pulsation of the capillaries themselves contributes more in the skin of the palm and sole and in the mucous membrane of the lip.

9. There is no evidence that pulsation is conveyed from arterioles to venules through the arteriovenule anastomoses.

Relation of Blood Pressure to the Amount of Renal Tissue.—Hilding C. Anderson (*Journal of Experimental Medicine,* May, 1924) used rabbits in which the amount of kidney tissue was reduced by operation or destroyed by the production of infarcts, in order to determine the effect on the blood pressure of a marked reduction of renal tissue. The amount of kidney parenchyma removed or destroyed was roughly seventy per cent. This did not cause hypertension, even when prolonged renal insufficiency resulted. By inference, then, the atrophy of renal tissue in chronic glomerulonephritis is not the cause of the accompanying hypertension.

Electrocardiogram in Prognosis. — C. F. Moffatt (*Medical Clinics of North America,* May, 1924) finds that significant T-wave negativity is not always associated with manifest clinical evidence of serious cardiac disease, and it is just in such cases that the electrocardiogram is of considerable aid. He has gained the distinct impression that this abnormal feature of the electrocardiogram is more apt to occur in conditions of progressive vascular degeneration involving in general the whole arterial tree, and in particular the coronary circulation, associated sometimes with symptoms of angina pectoris and very frequently found in cardiovascular disease with hypertension. He therefore believes that in the type of patient showing evidence of degenerative arterial changes, usually at first with hypertension, with symptoms of myocardial insufficiency, with or without anginal attacks, and frequently classified as myocarditis, the electrocardiogram may be of the greatest assistance in arriving at a more exact diagnosis and prognosis.

Can Variations in Ventricular Systole Be Determined from Electrocardiogram Deflections?—Elizabeth Bartos and Juius Burstein (*Journal of Laboratory and Clinical Medicine,* January, 1924) found in comparing electrical and mechanical systoles in different animals and men that the electrical systole (Q to end of T) is longer than mechanical systole by a variable and undeterminable interval. In dogs this involves at least an error of ten to twenty per cent., while in man the error was only three to five per cent. These differences are not due to variations in the QRS interval, but are due to inherent variations in the S-T interval. A comparison of the changes in electrical and mechanical systoles during altered conditions of the circulation showed that usually, but by no means always, the two changed in the same direction, but only rarely to equal degree. This was shown to be true when the heart was either slowed or accelerated, when the arterial resistance increased, and when venous return augmented. It is therefore concluded that waves of the electrocardiogram can be used as an index of ventricular systole only when no great degree of accuracy is required.

RHEUMATISM

Malaria and Articular Rheumatism.—Ladislaus Lichtenstein (*Wiener klinische Wochenschrift,* March 27, 1924) believes that malaria may be complicated by a febrile polyarthritis during its febrile stage, and also that this acute articular rheumatism may appear also in the second to the sixth week of the convalescence from the malaria. This articular involvement affects only the large joints in an otherwise uncharacteristic course and it is not markedly influenced either by quinine or by salicylates, but only by intensive thermal therapy. It is most likely that this polyarthritis is also due to malarial toxins.

Chronic Arthritis in the Adult, Associated with Splenomegaly and Leucopenia. A Report of Five Cases of an Unusual Clinical Syndrome.—A. R. Felty (*Bulletin of the Johns Hopkins Hospital,* January, 1924) describes five cases of chronic arthritis occurring in individuals of middle age, all of whom gave a history of marked loss of weight. In contrast to the prolonged course of the disease, and the ubiquitous distribution of the pain which is the presenting symptom of all the cases, the objective findings, by physical examination and x ray study, do not indicate a very damaging or destructive process. In every case the spleen was palpably enlarged, and in all but one there was a slight secondary anemia. There was a more striking leucopenia which was a distinctive feature of the disease. The leucocyte counts varied from one thousand to four thousand. In three of the five cases the lymph nodes were definitely enlarged. The author suggests that this syndrome is a distinct clinical entity, of which the outstanding symptoms are those related to the joints and the outstanding signs are the enlarged spleen and the blood picture.

Nature and Etiology of Rheumatic Fever.—Llewellyn J. Llewellyn (*American Medicine,* November, 1923) arrives at the fololwing conclusions: 1. There is a rheumatic diathesis, an innate predisposition to certain manifestations under favorable conditions. 2. Its hereditary transference is secured by the transmission of protein sensitization. 3. An ill balanced or vitamine deficient diet, through the structural changes induced thereby in the heart and alimentary mucosa, favors the occurrence of sensitization and accounts for the predilection evinced by the rheumatic virus for the heart, especially in children and adolescents. 4. The arthritic, cardiac and other phenomena of rheumatic fever are the outcome of anaphylaxis, working through the medium of vascular endothelial poisoning. 5. This same vascular endothelial poisoning, with its associated circulatory stases might possibly account for the phenomena of chorea. 6. The responsible antigens may be of bacterial, animal or vegetable origin. 7. The exciting causes in children are often alimentary disturbances, socalled bilious attacks; in adults most commonly muscular overexertion and exposure to cold. 8. These same exert their effect through acidosis and acidemia, which in older subjects may be of myogenous origin.

The Pathogenesis of Rheumatic Fever.—Homer F. Swift (*Journal of Experimental Medicine,* April, 1924), in a discussion of rheumatic fever, describes the histopathology of the cardiac and joint lesions, and of the subcutaneous nodules. He states that it is evident that there are two distinct types of response on the part of the body to the infectious agent of rheumatic fever, that is, proliferative and exudative. The perivascular proliferative type of lesion, resembling an infectious granuloma, explains the subacute and chronic character of the clinical symptoms in many patients with the disease. The acute arthritis occurring with high fever and general intoxication is accompanied by marked exudation of serum into the periarticular tissues and of serum and cells into the joint cavities. These acute exudations disappear following the administration of certain drugs, but this does not mean necessarily that all lesions of the proliferative type have resolved. In fact, the last mentioned lesions, when present in the subcutaneous tissues, often continue for months, and from analogy it is concluded that they have a similar persistent character in other tissues invaded by the causative agent of rheumatic fever.

Medicolegal Notes.

EXPERT TESTIMONY AS TO CAUSE OF DISEASED CONDITION

Action for damage was brought for the pinching out of a part of the flesh of the first joint of the plaintiff's right thumb by the negligent lowering of a crane. This received treatment and appeared to heal. Soon after this injury a boil appeared above the plaintiff's right wrist. Subsequently it was discovered that just below the elbow an infection had set in which later involved the upper part of the ulna and necessitated a removal of the upper two-thirds of it. The principal question was whether the boil or the injury to the thumb was the cause of the infection of the ulna. The plaintiff contended that the thumb injury caused the bone infection and this caused the appearance of the boil. The defendant insisted that the boil was not caused by the injury, but itself caused the bone infection. There was expert evidence offered in support of each of these theories. The trial court permitted expert witnesses for plaintiff to testify, over objection, and in answer to questions hypothesizing the facts, that the injury to the thumb caused the infection and disease of the bone.

The Missouri Supreme Court, O'Leary v. Scullin Steel Co., 260 S. W., 55, holds that the admission of this evidence was proper, and that the rule formerly favored by the decisions of the Missouri courts, under which the admission of such evidence would have been held error, as an assumption by expert witnesses of the province of the jury, should no longer be followed. In the course of exhaustive discussion of the rule and the prior decisions, the court said: "With respect to the question in this case there is no reason to exclude the expert's opinion as to the cause of the bone infection. No layman could tell from the evidence (other than that of the experts), whether the thumb injury or the boil caused that infection. The only evidence which, to the lay mind in the jury box could be said to have any efficacy, to point to one rather than the other as the cause of the infection, is that of experts. In this situation our law steps in, and by the rule of the preceding paragraph directly forbids the expert to say more than that the wound or the boil, or both, 'might or could' cause the infection of the bone. The jury is then in this situation: It has before it no evidence on which it can form an independent opinion as to the cause; it has expert testimony that the injury to the thumb 'might or could' cause the bone infection; it has before it other expert testimony that many other things might or could cause it; it has no testimony that either the wound or boil, or anything else, did cause it. . . . In the instant case the jury cannot, without expert testimony, get at the cause from the other evidence, because the evidence has no tendency to prove to the lay mind a relation of cause and effect. It could not logically find the cause from the expert testimony if the rule in question is applied to restrict expert opinion to what might or could result from the injury, since that does not necessarily go further than a possibility, and a mere possibility does not satisfy the burden of proof."

AUTHORITY OF EMPLOYER'S SUPERINTENDENT TO SEND INJURED EMPLOYEE TO HOSPITAL IN EMERGENCY

In an action by the owners of a hospital against a construction company engaged in building bridges, for the treatment of an employee who was sent to the hospital by the defendant's superintendent, on the advice of the local doctor, suffering from fracture of the spine, crushed vertebrae and paralysis of both legs, injuries sustained while in defendant's employment, the North Carolina Supreme Court held, Miller v. Cornell-Young Co., 187 N. C. 549, 122 S. E. 383, that the superintendent who had entire charge of the construction work and had authority to buy materials and repair the broken machinery and employ and discharge the workmen, had implied authority to authorize the plaintiffs to care for and administer to the fatally wounded employee. It was an emergency case and a continuing one. Judgment for plaintiffs was therefore affirmed.

EMPLOYMENT OF PHYSICIAN BY INJURED EMPLOYEE

Under the Oklahoma Workmen's Compensation Act the employer has the right to name the physician to render medical treatment to an injured employee, but may waive this right. When the employer does so, and knows that the employee is going out of the community for treatment and makes no objection thereto, the employer likewise waives proof that the bills are reasonable for the same class of treatment in the location where the injury occurred.

Where the employer furnishes a physician for first aid treatment, and in the presence of the employer such physician advises the injured employee to go elsewhere for treatment, and the employer consents thereto and advises that it is the thing to do, and reports to the Industrial Commission that the injured employee has been sent to a hospital for treatment, it is held that the Commission is authorized to excuse the employee from making formal request upon the employer for treatment, and may likewise excuse the employee from making proof that the bills paid and to be paid are reasonable, and such as would have been charged a patient in the same station in life as the employee and in the community where the injury occurred.—Scruggs Bros. v. State Industrial Commission (Okla.), 221 Pac. 470.

IN ACTION ON QUANTUM MERUIT FOR SERVICES DEFENDANT HAS BURDEN OF PROOF OF DEFENSE OF SPECIAL CONTRACT

In an action by a physician on quantum meruit for the value of services rendered to the defendant's wife there was no dispute as to the fact that the service was rendered to the wife in childbirth or that it was entirely satisfactory. The defendant's contention was that he and the physician made a special contract covering the service, by which the physician was to be paid $35, plus mileage, $3.50. The jury rendered a verdict for $38.50, and the plaintiff appealed. The sole question was as to the burden of proof.

The South Carolina Supreme Court held, Pittman v. Le Master, 121 S. E. 677, that when the plaintiff sues upon a quantum meruit and proves the services and their value, he makes out a prima facie case upon the reasonable theory that an implied contract has been established to compensate him for their reasonable value. If the defendant relies upon a restrictive express contract fixing the amount of compensation, he must set it up as an affirmative defense, the burden of establishing which is on him.

In the present case it was held that the trial court correctly charged the law as to this, but nullified it by also charging that if the evidence was evenly balanced the plaintiff must lose; and judgment for defendant was reversed and a new trial ordered.

MUNICIPALITY MAY REGULATE PASTEURIZATION OF MILK

The North Carolina Supreme Court holds, State v. Edwards, 121 S. E. 444, that a city in the exercise of its police power may require milk for human consumption to be pasteurized, and may prescribe reasonable regulations under which the pasteurization shall be done. A municipal ordinance requiring pasteurization of milk and requiring those selling it to procure a yearly license, under penalty for violation, is held to be reasonable and valid.

Trustworthy!

The extent to which innumerable practitioners of medicine are today employing

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

whenever a dependable reconstructive tonic is called for, tells in no uncertain way of its therapeutic utility and gratifying efficiency.

During the thirty-five years this reliable tonic has been at the service of the profession, the quality of its ingredients and the unvarying character of the composite product have been consistently and faithfully maintained.

Thus it is easy to understand why the host of medical men who have learned how reliable it is in its character and results, not only take pains to order the original Gray's Glycerine Tonic Comp. (P. F. Co.), but also to see that their patients get no other!

Such care is well worth while, for it often measures the difference between success and failure.

The Purdue Frederick Co., 135 Christopher St., New York

Valentine's Meat-Juice

Whenever the **Stomach** from any cause **Rejects Food** or **Medicine, Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** to **Restore** and **Strengthen.** In the **General Debility** with **Impaired Digestion** of **Phthisis,** and in the **Depressing Prostration** following **Influenza** it is recommended by many practitioners throughout the world as invaluable in their treatment.

Phthisis.

J. Mertens, M. D., *A. T. O. Bristol Municipal Tuberculosis Dispensaries, Bristol, England:* "I am pleased to state that the results obtained from VALENTINE'S MEAT-JUICE were very satisfactory indeed in all cases where no other kind of food could be used. It produced excellent results with wounded soldiers suffering from Tuberculosis of the lungs."

Dr. Gouel, *Physician in Chief Villepinte Hospital for Consumption, Paris, France:* "VALENTINE'S MEAT-JUICE succeeds well in cases of Anæmia and in the treatment of Tuberculosis in an advanced stage when the stomach is intolerant."

Physicians are invited to send for brochures containing clinical reports.

For sale by American and European Chemists and Druggists.

VALENTINE'S
PREPARATION
NUTRIO PRIME
MEAT JUICE.
The result of an original Process of Preparing Meat, and extracting its Juice, by which the elements of nutrition are obtained in a state, ready for immediate absorption.
DIRECTIONS.-Dissolve one teaspoonful of the Preparation in two or three tablespoonfuls of cold or warm water. The use of boiling water changes the character of the preparation.

Miscellany.

Race Progress.—Until comparatively recent times the alleviation and cure of disease were the sole objects of the medical practitioner, whereas today his ultimate aim is its prevention. Since the advent of the National Insurance Act it has become manifest that however efficient it may be for treatment, the scheme makes no provision for preventivé medicine, and the success, or otherwise, of the forthcoming Royal Commission will be gauged by its power of devising some practicable method of providing the means of discovering and countering the beginnings of disease in the adult population. Ill or well, at regular intervals, each individual should not only be offered, but induced to accept, a medical examination free of cost, on the lines suggested by the late Dr. Lauriston Shaw, and adopted by certain life insurance companies. The school medical officer has facilities for obtaining a consultant's opinion and institutional treatment for those children who require them. In the course of his duties he examines periodically, whether ill or well, different age groups, and has before him the personal and family history and the record of previous examinations. He is thus able to note the effect of time and growth upon the conditions described in the report, and in many instances to compare the condition of those cases which have undergone treatment with others of the same nature where treatment has been refused. His opportunities of detecting the beginnings of disease, and of urging upon parents the importance of regular attendance at hospital or clinic are exceptional. The only thing lacking is the power to make sure that the children shall receive such treatment as is deemed by competent authority to be necessary for their own wellbeing, and through them for the progress of the race.—(*Medical Press,* October 15, 1924.)

The Smoke Nuisance.—Every large city and many smaller manufacturing communities suffer from excessive smoke. Anything which obscures sunlight and contaminates the air may affect health, says an editorial writer in the *Boston Medical and Surgical Journal,* October 30, 1924. Smoke is also a financial burden because it necessitates more time and expense in keeping clothing and dwellings clean and represents fuel waste.

Large cities are paying especial attention to the problem of diminishing the amount of smoke. With characteristic energy Chicago has made a definite campaign against the smoke nuisance through transfer of the enforcement of the smoke ordinance to the Department of Health. The known violations of the ordinance in this city amounted to 1,468 cases in 1918, reaching the figures of 8,284 in 1920. In 1918, sixty-eight chimneys out of every hundred observed were violating the ordinance, but in 1924 only twenty per cent. were at fault.

Including fuel waste, as well as direct damage, it has been estimated that smoke has caused a loss of $42,500,000 a year in Chicago, and the irritation of the air passages is supposed to favor the development of respiratory diseases and may have a definite effect in increasing susceptibility to tuberculosis.

Chicago's example has led to the estimate that there are probably 16,000,000 amateurs managing fuel consuming plants in the United States with a great financial loss. This means that even the small consumer of fuel may do his part toward lessening the smoke nuisance as well as saving money. He should be ambitious to aid in health maintenance as well as to practise economy.

Monthly Reports on Vaccinations and Revaccinations Required by Public Health Law.—The attention of physicians is again called to section 311 of the Public Health Law which requires that every health officer shall report to the State Department of Health at the end of each month the number of primary vaccinations and the number of revaccinations performed in his community during the month.

For each of these types of vaccination the attending physician should supply the health officer with the number of cases in his practice having vaccinia or primary reaction, the number showing vaccinoid or accelerated reaction, the number of those showing immune or immediate reaction, the number of failures and the number of reactions unobserved or unrecorded.—*Health News,* October 27, 1924.

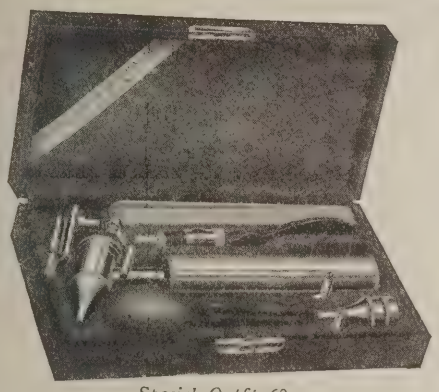
Industrial Accidents to Working Minors.—According to a study just completed by the Children's Bureau of the U. S. Department of Labor, 7,478 industrial accidents to young workers under twenty-one years of age occurred in one year in three States. Thirty-eight of these accidents resulted in death and 920 in partial disablement for life. Wisconsin, Massachusetts and New Jersey were the states included in the study. The cases of industrial accidents to minors were secured from the files of State Industrial Commissions and Accident Boards and were only those in which compensation had been paid: that is, in Wisconsin, accidents causing disability of more than seven days' duration; in Massachusetts and New Jersey, accidents causing disability of more than ten days' duration.

The smallest number of accidents and the lowest accident rate occured in the case of children under sixteen. Each of the States studied had attempted to protect children under this age by prohibiting them from employment in certain occupations, chiefly in the operation of the more dangerous machinery, which is the source of greatest accident hazard to the young worker. Children of sixteen and seventeen were prohibited from some employments in Massachusetts and Wisconsin, but in all three states were permitted to operate many of the dangerous machines.

Accident figures reflected this difference in legal protection. Power working machinery caused a larger percentage of the accidents to workers sixteen and seventeen years old than to children under sixteen—protected by law—or to young workers between eighteen and twenty-one, who were better able to protect themselves. Accidents were also more serious to the sixteenth and seventeenth year group than to either the younger or older workers. Of the injuries to workers under sixteen, 10.7 per cent. resulted in death or partial disablement for life. For those sixteen and seventeen years old who were injured, the rate was 13.4 per cent. killed or permanently disabled; for the group eighteen to twenty-one years the rate was 12.7 per cent.

For Accuracy in Diagnosis

use genuine "E. S. I. Co." Electrically Lighted Instruments



Special Outfit 60

Ophthalmoscope, Auriscope and Tongue Depressor, with Universal Battery Handle

To obtain proper service from our instruments, make certain you are using genuine "E. S. I. Co." lamps. For your convenience in ordering correct lamps, write for a copy of our Lamp Sheet.

Our twenty-five years of service to the Medical Profession and the fact that our instruments are made in accordance with the suggestions and with the co-operation of the eminent physicians and surgeons whose names they bear, is the best guarantee of their satisfactory character.

ROCHESTER, N. Y.

Intestinal Stasis

as Lane has shown, is responsible for more diseases than any other one cause. Unfortunately, its correction presents many difficulties.

In AGAROL COMP., however, the practitioner has at his command, a unique combination of mineral oil, agar-agar and phenolphthalein, that not only will produce thorough elimination from the bowel without nausea, griping or distress, but also, when systematically employed, will restore the muscular tone and functional activity of the intestinal canal.

A constantly increasing number of medical men, therefore, are employing Agarol Comp. in the treatment of intestinal stasis, for they have found that its systematic use for a reasonable period means the permanent restoration of bowel function, after which it may be discontinued with the gratifying certainty that regular evacuations will follow without further assistance.

AGAROL is the *original* Mineral Oil—Agar-Agar Emulsion, and has these special advantages: Perfectly homogenized and stable; pleasant taste without artificial flavoring; freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage; no griping or pain; no nausea or gastric disturbance; not habit forming.

A generous supply for thoroughly testing Agarol Comp. will be sent on request.

Manufacturing Pharmaceutists since 1856

113-123 West 18th Street New York City

Adapting Nutrition Work to a Community.—The New York Association for Improving the Condition of the Poor has issued a report prepared by Miss Lucy H. Gillett, superintendent of its Nutrition Bureau, describing the methods employed, and summarizing the results of, an intensive campaign against malnutrition which the A. I. C. P. has been carrying on in the Mulberry district of New York City.

The report states that of 2,181 apparently well children examined in the medical clinics at the Mulberry Health Centre, 656, or thirty per cent., were diagnosed as malnourished. Since much of the sickness and lowered vitality in later life is the result of poor nutrition, as physicians have frequently stated, the importance of providing educational guidance in nutrition as well as providing attention for the correction of physical defects is of tremendous importance.

If these children were in danger from fire or industrial accidents, the report states, every safety device and preventive measure known would be urged to protect them. Although the results from malnutrition are much slower, often much more indirect and much less dramatic than those from fire or accidents, they are even more deplorable because of the larger number affected and the lingering misery resulting.

Many a wage earner is unable to increase his income to the safety level because of health conditions due to poor nutrition. Too many children who apparently show no signs of disease or malnutrition are allowed to drift into the wage earning period with only a part of their rightful earning capacity developed. Thus handicapped there is danger that they may add to the responsibility of the health and social agencies.

Miss Gillett's report states that before any method for combatting malnutrition can be decided upon, it is first necessary to determine, 1, what nutrition work is being done and what other nutrition work should be done in the district; 2, what is the prevailing nationality, and what is their social and educational background; 3, are preventive or curative aspects of nutrition to be emphasized, or both; 4, shall the work be conducted in the interest of the preschool child, the school child, the adult, or for everyone in the community; and 5, what method shall be used.

The problem may be approached through small groups, through intensive work in individual families, or through general educational work with large groups, or a combination of any two or all three. The small group may be used with school children or intelligent mothers or preschool children. It is useful in either a curative or preventive program. There are arguments for and against nutrition work exclusively in groups.

The following arguments for the group method are advanced: 1. One small group frequently arouses the interest of a whole neighborhood by providing a graphic illustration. 2. A large number may be reached in a short time. 3. The class spirit often gives a child courage to venture on new habits. 4. Because cooperation is frequently secured more quickly, the class sometimes reduces the number of home visits required.

Arguments against the group method are: 1. Home conditions cannot be as completely corrected —the work is not as thorough. 2. The class spirit which prompts some good habit formation is removed when the class is over and children are apt to return to old habits. 3. Too many children are living under conditions which they are powerless to correct and about which the parents are indifferent. 4. In such cases home visits are necessary. Home visits in addition to the class period and preparation for it often take more time than home visits alone. 5. The preschool child himself can be taught comparatively little in groups. The intensive work in the home could often be done in the time it takes to get mothers to come to class. 6. Each worker has to decide for herself whether her conditions are favorable for group work. 7. Intensive work is always a necessary part of the curative program in cases where individual problems exist or where the cooperation of the parents is difficult to obtain. 8. General educational work may be used most effectively as a preventive measure, though doubtless much malnutrition may be cured thereby too.

During the four and one half years of intensive work covered in the A. I. C. P.'s report, intensive care was given to 1,018 malnutrition cases and in addition the habits of all the boys and girls in the families of these special malnutrition cases were influenced. With an average of 3.8 children to a family, 2,578 children received attention. There is much evidence that the work spreads to other families in the neighborhood, but such results are hard to estimate. We frequently hear of mothers who give milk and cereals to their children because children under our care were advised to use these foods.

Group work would naturally seem more economical of time than intensive home visits, but it was extremely difficult to get these women (who were mostly Italians) out at stated intervals and much time was lost thereby. The average cost per visit in a home has been estimated to be thirty-seven cents. The average cost per person per lesson where the women were taught in groups was estimated to be thirty-six cents, with an average attendance of eight per lesson. With practically the same cost per individual and with more satisfactory results from intensive work, in this particular neighborhood the malnourished preschool child was handled more economically through intensive work than in groups. School children can doubtless be handled more economically in large numbers.

Diarrheal Outbreak Results from Polluted Spring.—Under date of October 9, 1924, Dr. Sears, district state health officer, reported an explosive outbreak of diarrhea which occurred in Onondaga Valley, New York. The outbreak involved seventy-eight of the eighty-nine members of the twenty-three families living on a certain street in Onondaga Valley, all of whom received their drinking water from a private spring. The spring is believed to have been polluted through the increased rate of seepage through the soil due to a heavy rainfall which occurred two days previous to the outbreak. The cases were characterized by vomiting, diarrhea and intestinal cramps, and in a few cases by some fever.—(*Health News*, October 27, 1924.)

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Junior Red Cross Dental Work in the Philippines.—Those of us who overeat may dig our graves with our teeth, but that is not a sufficient excuse for us to neglect them. Indeed, we are beginning to realize that though a good set of teeth is not necessarily synonymous with good health and longevity, bad teeth may bring disease and materially shorten life. In the near future it may be considered an even greater crime to have neglected teeth than to present a dirty face to the world, and the Junior Red Cross in the Philippines is assuredly doing much to promote this much to be desired attitude.

The children of the Philippine Islands have made themselves financially responsible for a scheme as sound as it is comprehensive. Every centavo of their membership fund is spent in the provinces on dental work—salaries for dentists, the maintenance of dental clinics, and the purchase of dental material, etc. The direction of the Junior Red Cross Work in the Philippines from June 1, 1922, to January 1, 1924, was in the hands of Miss Anna B. Cowles who found awaiting her an enrolment of 99,000 children in the schools. By May 31, 1924, there was, thanks to the hearty cooperation of school officials and others, an enrolment of 700,141 children whose contributions went to the support of sixty-five dental clinics and other activities. These clinics serve all children in those public and private schools which are enrolled as Junior Red Cross Auxiliaries, regardless of whether the individual child has contributed to the Service Fund or not. Only in extreme emergencies and when the services of no private dentist can be obtained, is treatment of adults allowed. Here is an imposing table giving a summary of the work from June 1923 to May 31, 1924.

No. of dental clinics established	65
No. of children inspected	274,940
No. of children with defects	188,407
No. of treatments	163,081
No. of extractions	137,413
No. of fillings	120,913
No. of corrections	70,249
No. of cleanings	184,054

Tooth brush drill is taught and tooth brushes are given to the children too poor to buy them. A total of 62,356 tooth brushes was provided in the year reviewed. The activities of the Junior Red Cross in the Philippines are not limited to dental hygiene, but this is evidently its specialty and one of which it may be very justly proud.—(*The World's Health*, October, 1924.)

Fewer Births Attended by Midwives.—During 1924, to date, 411 midwives' licenses have been issued by this department. Of this number 15 were new licenses and 369 were renewals. During 1916 licensed midwifes in this State exclusive of New York City reported sixteen per cent. of all the births. There has been a gradual falling off in the percentages of births reported by midwives, until in 1923 out of a total upstate registration of 101,729 births, midwives reported 9,447 or 9.3 per cent. Even in the cities where there is a large foreign population there appears to be a reduction in the number of births midwives are attending. There is also marked improvement noted in the type of women doing the work; the undesirable element is being eliminated.—(*Health News*, October 27, 1924.)

The Common Cold*

HARMON SMITH, M.D., Sc.D.
New York

I offer no apology for presenting a paper upon a subject so simple and of such clinical frequency that not only the profession but the laity feel themselves adequately qualified to cope with it, for it is the observation of all physicians that if colds could be eliminated in the same manner as yellow fever, malaria and diphtheria, a large proportion of ills to which flesh is heir would be relegated to oblivion.

Colds may be classified in the following manner: First, stomachic or digestive; second, vasomotor; third, infective; fourth, exanthematous.

I shall consider only the first three, as the exanthematous belong particularly to the realm of the pediatrists.

STOMACHIC OR DIGESTIVE

Etiology.—In these cases there is ordinarily an acidosis or a tendency thereto. The individual is habituated to the frequent use of soda bicarbonate, bisodol, milk of magnesia or other antacids, ignorant of the fact that all of these may induce an excess of hydrochloric acid in the stomach and increase rather than diminish acidity. Lithemia, gout, rheumatism and like conditions frequently underlie this type. They occur mostly in summer and autumn when the subject partakes freely of the fruits and vegetables then available, such as berries, tomatoes, melons, grapes, apples, cider and other acid fruits.

Symptoms.—The most frequent location of the initial discomfort is the nasopharynx. It is ushered in by an itching, burning sensation in the nose and nasopharynx followed by a sense of puffiness and inability to breathe. There is frequent sneezing due to pressure in the upper third of the nose, but is unassociated with the profuse nasal discharge characteristic of the infective cold. Headache and lacrimation are also less evident. These colds are variable in duration, proportionate to the response to treatment. There is no pathological change worthy of note.

Treatment.—Foods which have apparently been at fault should be eliminated. There are many known instances where strawberries are practically a poison. There is a distinguished member of our profession living in New York City, who is so susceptible to strawberries that it takes only three to make his nose shut up entirely, throw him into a high fever and cause a rash to appear over his entire body.

Antigout, antirrheumatic and antacid medication is of value after the elimination of the food elements, to be followed by daily doses of sal hepatica for a week or more. Exercise, sweats, free use of water, and corrective diet are prophylactic measures to be insisted upon. High colonic irrigations in cases of intestinal stasis and putrefaction, followed by implantations of the bacillus acidophilus has lessened this type of cold in many of my patients. The change of the intestinal flora by any means is beneficial.

VASOMOTOR

Etiology.—Here we have the most complicated and the most unsatisfactory type with which to contend.

The neurotic, and those on the borderline, whom we may class as high strung, not only in women, in whom it predominates, but in men living under high tension, as stock brokers, gamblers, professional men, and those upon the stage, as actors, actresses or singers, are all subject to this type of colds. To these may be added boys and girls at the time of puberty, and women at the time of the menopause. That there is a definite relation between the erectile tissue in the nose, and the functioning sexual organs in both women and men, is beyond question. Hence in girls at the beginning of menstruation, and boys when the voice is changing, the nasal mucous membrane is congested, the breathing is impaired, headaches are frequent, mental acumen is lessened, energy is reduced, and the optimism of youth is lowered. The colds, socalled, of puberty, are known to all, and the specialist who endeavors at this time to give the sufferer more room for breathing by operative intervention is violating all the laws of nature, and will subject the patient to the probability of a dry scabby nose during subsequent years of life. Bearing upon this physiological phenomena, it may not be inappropriate to call attention to the fact that an abused physiological function may ultimately become a pathological entity. During sexual excitement, the mucosa becomes turgescent, and in the erotic or in those frequently addicted to sexual indulgence, this becomes permanently engorged. Fibrous elements will ultimately replace the elastic fibres which enable

*Read before the Colorado Congress of Ophthalmology and Otolaryngology at Denver, Colorado, August 2, 1924.

Copyright, 1924, by A. R. Elliott Publishing Company.

the membrane to swell at one time and retract at another. This frequent engorgement finally becomes a permanent hyperplasia and the individual complains of constant nasal stoppage, inability to breathe, and the loss of the sense of smell. They are constantly blowing the nose without satisfactory results, sleep with their mouths open, awaken with a dry throat, and complain of the discomforts characteristic of a chronic cold.

Treatment.—To overcome this type of cold, it is necessary that the subject should change his environment, alter his method of living, and modify his indulgences, which is almost an impossible task to ask of the specialist. In those with hyperplastic mucosæ, operative measures are often satisfactory. Patients who live under high tension, eat unwisely, take no exercise, sleep irregularly, live in close offices, etc., can benefit by modifying these conditions, but in my experience, permanent relief has been most difficult to procure.

INFECTIVE COLDS

Etiology.—1. Predisposing. Puberty, menopause and reduced vitality from old age or other causes, are the three most potent predisposing conditions to infections in the nose. Next in order are irregularities of the septum underlying dyscrasias such as lithemia and acidosis; vocations, as in miners, coal heavers, chemists, manicurists, office workers, laboratory workers, teachers and other indoor workers. The farmer, soldier, carpenter, hod carrier and other outside worker is peculiarly free from colds.

Neither extremes of cold nor heat play a definite part in catching cold. Soldiers submitted to exposure, explorers experiencing every extreme of cold and heat, ranchmen sleeping in the open without cover, are all phenomenally free from infective colds. Stefansson, the Arctic explorer, has stated that when he and his men passed beyond the habitat of civilization, colds, bronchitis and pneumonia were unknown. Large bodies of troops in campaigning, even when submitted to all the inclemencies of weather and without adequate protection, will carry on for long periods of time free from epidemic colds.

2. Active. Although there may be found, upon microscopical examination, nearly every form of bacteria in the secretions from the normal nose, yet a predominance of one or more type will often characterize an infective cold. In large cities, particularly, the nasal mucosa is not only the constant host of the Bacillus catarrhalis, but also of various forms of the staphylococcus, the streptococcus, the pneumonia bacillus, the influenza bacillus and even in rare instances of the colon bacillus and the gonococcus.

Why, then, in the presence of this variety of organism does the individual not always present the evidences of a cold? For the simple reason that resistance plays the part that invariably determines the status between health and sickness. Granting the almost universal presence in the nose of these microorganisms, what is it that enables them at one time to produce the symptoms of a cold and at another remain inert?

First, there is some shock to the sympathetic nervous system, due either to digestive disturbances, lowered bodily resistance from exposure to draught, overindulgence is alcohol, excessive mental or physical fatigue, or prolonged existence in a vitiated atmosphere, and as a result of these there follows a lowered surface tension of the mucous membrane. A biochemical change occurs, permitting the ever present microorganism to gain entrance to the submucosa, paralyze the phagocytic action and minimize other elements existing there for its protection. The surface tension, which is one of balance, is undermined, and the streptococcus or its allied bacteria penetrates beyond the surface and produces all the discomforts and symptoms of an infectious cold.

Sometimes the toxin produced by the invasion of the microorganism is met by an antitoxin which ameliorates if it does not destroy the potentiality of the invading germ, but most frequently the resistance of the individual is such that the organism and its toxins overcome the protection offered by the antitoxins and the gradations of an infective cold follow.

PATHOLOGY

There are three stages of pathological change in an infective cold: First, prodromal or dry; second, exudative or wet; third, mucopurulent.

PRODROMAL OR DRY STAGE

The first condition represents the immediate invasion of the organism and nature's endeavor to repulse it. It is one of inflammation as presented anywhere and is manifested by swelling, hyperemia and discomfort. The mucosa is turgescent and dry. The arterial supply is increased, the venous drain is retarded owing to the pressure from expansion, the muscle around the racemose glands supplying mucus is contracted, the gland itself not being able to discharge its content is distended and for a period, varying from a few hours to even a day, the surface mucosa is red and dry.

EXUDATIVE OR WET STAGE

The second period begins with an abundance of elimination from the mucous glands, as the muscle surrounding its exit has become paralyzed and upon relaxation the surcharge of mucus held back pushes forth unrestrained. The veins begin also to function but inadequately and extravasation of serum through the meshes of areolar tissue takes place and adds to the mucus from the racemose glands and we have the watery stage of the cold. The elastic fibres of the mucosa have partially regained their function and squeeze the membrane so that further elimination of foreign matter takes place. After a variable period of one to several days the cold enters the third period or the

MUCOPURULENT STAGE

We now have the terminal pathological condition where nature is exercising every effort not only to eliminate the infective organisms, but to throw off the products of inflammation produced by their presence.

The discharge is one of mucus, serum, lymphocytes and accumulated detritus incident to this disorganization of the normal function of the mucosa. Wherever and whenever inflammation occurs there follows a replacement of the normal tissue by a certain amount of fibrous tissue and in proportion to the

frequency thereof, just so far are the functioning properties replaced by nonfunctioning scar tissue. When carried, in the nose, to its ultimate end, there will obtain a hyperplastic or hypertrophic rhinitis.

SYMPTOMS

Both subjective and objective symptoms occur coincident with the pathological changes of the three stages. To enumerate them all would be tedious and to the disregard of the skilled clinical observations of those present.

The first period, the prodromal or dry, is the most uncomfortable for the patient. There is burning and itching in the nasopharynx, nose and eyes; sneezing, headache, chilly sensations and possibly fever. This period is temporary and only occasionally the specialist sees the mucosa in this condition of marked inflammation. There soon follows the second stage of profuse watery nasal discharge, lacrimation, fullness in the ears, loss of resonance, loss of smell, cold sores, etc., so familiar to all. During this stage, the Eustachian tubes and accessory sinuses frequently become involved owing to either infection by continuity or forcible entrance of air laden with the infective secretions. After a few days, if the cold is not aborted, the discharge becomes thick, tenacious, stringy, sometimes blood stained, and the effort to dislodge it from the mucous membrane is often attended by dire results. The quantity of discharge blown from the nose is, in a number of instances, too great to be produced by the outflow from the mucosa alone, and I believe that the sinuses are unquestionably involved in these cases. The terminal stage often extends into days or weeks, in accordance with the ability of the individual to throw off infection, and also proportionate to the success of the doctor in combating the disease. Cooperation on the part of the patient is very important, for disregard of instructions and infrequent treatment prolong the date of recovery.

TREATMENT

Prophylactic.—Correction of septal deformities, reduction of hypertrophies, combating acidosis, regulating diet, ventilating sleeping quarters, instituting systematic outdoor exercise, eliminating flannel underwear except in the old and very young, and substituting therefor linen mesh or similar material, insisting upon cold sponging, cold showers or cold plunges in the morning according to the resistance and reaction of the individual; advising the patient predisposed to colds to avoid crowds, not to use subways, not to attend horse shows nor the circus, particularly at the season of the year when colds are prevalent. Admonish the parents to isolate the member of the family having a cold, and to employ gauze upon which to blow the nose, which can be burned, rather than a handkerchief. A handkerchief when frequently used and withdrawn in the presence of others, wafts an infected breeze to whomsoever is near. It likewise is handled by the servant collecting the laundry, to whom the cold may be distributed, again handled by the laundress, both of whom become additional foci for the spread of the infection. Until we all recognize the advisability of such prophylaxis and insist upon its execution, colds will continue to become epidemic.

Direct.—Here again the three pathological steps must be considered as the basis for treatment. In the prodromal or dry stage, an effort must be made to hasten and abet nature's method to eliminate the organism of invasion and its toxins. To apply locally any medication that will tighten surface tension, as adrenalin and cocaine, or to administer internally any drug that will dry the surface, such as belladonna, is to disregard the functional economy of the mucosa and retard nature's methods of recovery. The old time practice of administering quinine, belladonna, etc., is contraindicated.

Just as the general practitioner endeavors to abate fever by calling upon the skin, kidneys, bowels and lungs to eradicate the poisons producing the fever, just so should the specialist endeavor to make not only all of these functions cooperate, but also make the mucous membrane "sweat." Some of the simpler methods of former practitioners seem to promote this outcome more than later therapy. If possible, get the patient to bed. In the prodromal stage, give to an adult ten grains of Dover's powder on retiring, a hot lemonade with whiskey, rum or brandy in it, a hot mustard foot bath, and cover up with blankets until a good sweat is induced. The next morning, a large dose of sal hepatica, or citrate of magnesia is administered to counteract the effect of the opium. Should the second or watery stage have appeared by the next day, have the patient remain in bed and have him drink large quantities of cream of tartar water, or give frequent doses of liq. ammon. acetatis, or frequent small doses of aconite.

In the first stage, I never treat the condition by local application, except by steam inhalations with the head covered up and for this I employ a mixture of:

Tincture Benzoin } āā dr. 1
Ol. Pini. Pumil. }
Menthol M. x.
Milk of Magnesia qs. ad. oz. iv
Sig: Dr. 1 to pint boiling water inhaled at hour intervals from a benzoinol inhaler.

When the second or watery stage begins I irrigate the nose from the nasopharynx forward, by means of a postnasal syringe, using equal parts of Dobell's solution and hot water, followed by either five per cent. argyrol solution in warm water or collene, one part to two parts of hot water. After this, I let the patient inject into the nose a small quantity of a nose cream, which I have employed for years, consisting of: carbolic acid, menthol, camphor and liquid oleostearate of zinc.

This cream is soothing, slightly antiseptic and conveniently put up in tubes for use by the patient. For a variable time, according to symptoms, I carry out this routine daily or even twice a day, if the patient agrees with the argument that a cold that is overcome within a day or so is of inestimable economic value, not only in enabling him to accomplish more mentally and physically, but by preventing a large number of possible sequelæ.

The advocacy and employment on the part of the patient of nasal sprays, douches, salt water irrigations, etc., are not only ineffective, but dangerous to the patient. The infective organisms collected in the entrance to the nostril on the vibrissæ and likewise distributed along the curvatures of the nasal

fossæ are forced backward toward the Eustachian tubes and are distributed to regions previously uninvolved. I also deprecate the employment of nasal sprays in any case of cold, as the pressure now at command from the Sorensen pump is too freely employed, and often creates trauma, and drives the infective material from the front of the nose backwards towards the Eustachian tubes.

When the cold has reached the third or mucopurulent stage, some of the proprietary remedies, such as coryza tablets, rhinitis tablets, and similar preparations, may give some relief, but even here local treatment is far more effective. In this stage, I apply on the same pledget of cotton, a one in sixteen thousand solution of adrenalin in rose water or camphor water, and a one per cent. solution of cocaine, lining out the pledget along the curvature of the swollen turbinates. After leaving in situ for about two minutes, I remove it, and if sufficient shrinkage has taken place I irrigate the nose from one side to the other with the head bent well forward and the patient's body flexed so that a large volume of the solution is permitted to run, without force, from one side out the other, without endangering the Eustachian tubes or sinuses. Unless this method is carried out without employing force and unless the patient is instructed to open and breathe through the mouth rather than the nose, untoward results may obtain.

This douching with a large quantity of fluid brings away all or nearly all of the thick ropy secretion and frees the membrane for the application of the medication to follow. I employ a Douglass douche and an alkaline powder called alkanos, which simulates glycothymoline in appearance and acceptability, but is cheaper and in a more easily handled form. There is no particular value in alkanos, and either seiler, mucol, or even salt water made from sea salt is equally effective. Salt, however, is very drying and leaves a smarting sensation if used too strong.

After cleansing the nostrils with one or more douches, on each side, I put in pledgets of cotton soaked in equal parts of collene and water, and if the patients will permit, leave them there until they return home or to their work, if either is not too far distant. I believe that our results from local treatment are often failures because we leave the medicaments in situ insufficiently long to obtain their full benefit. In particularly tenacious discharges, I often give drop doses of potassium iodide four times a day to increase the watery and lessen the thick discharge. The local application of Mandle's solution of iodine will also accomplish the same purpose.

The value of argyrol in low percentage is questionable, but if used in twenty to thirty per cent. and left in the nose for half an hour, it is unmistakably of value even in sinusitis. In catarrhal sinusitis incident to colds, I also employ interrupted suction, and frequently use my sinus suction syringe, which when a vacuum is created and then released, the medication in the syringe can be forced into the sinus from which the secretions have been sucked.

To stop treatment in any stage before complete extermination of the infective organism has been accomplished, is to invite a recurrence of all symptoms due to a reinfection from a new invigoration of germs, or a new colonization from those uninfluenced by the antiseptics employed.

VACCINES

Autogenous vaccines have in my hands been no more effective than the socalled stock vaccines. In some instances, I have seen marvelous results follow the employment of vaccines, while in others I have not been able to note any benefit. This applies to both autogenous and stock vaccines. I have a few patients who have for years had autogenous vaccines in the autumn, and from their statement their colds have been reduced to a minimum. As vaccines do no apparent harm, I can see no reason why they should not be employed, even though in the experience of a number using them, little or no definite results can be noted. I have not employed the chlorine treatment, but anticipate some good results from its employment.

Though presenting to you a perfect primer of facts, relative to a subject as old as medicine itself, I nevertheless hope that its rambling nature may induce comment more accurate and more pertinent to the subject, and which will be of profit to us all.

44 West Forty-ninth Street.

Induced Increase in White Blood Cells—Its Effects on Infection

BURR FERGUSON, M.D.
Southampton, England
Medical Officer in Charge, U. S. Public Health Service.

The difficulty in doing anything worth while in the treatment of furunculosis is particularly impressive to one doing industrial medical work. The local measures of incision, drainage and dressings furnish treatment only for the result, not for the cause of the infection. All too often in the use of autogenous vaccine, there is a cessation of the infection only, during the repeated injections. In many cases when the vaccine is not given the boils reappear.

In every case of well established furunculosis a culture of the blood of the infected individual will show colonies of the staphylococci and streptococci.

Knowing the immediate and marked effect of salicylate of mercury in the treatment of syphilis, I made an effort in 1916 to apply the same measure in an obstinate case of furunculosis, in the belief that if the mercury was so potent in decreasing the number of the treponemas, there was a reasonable chance that the same result would be obtained in the case of furunculosis. An injection of one grain of the

salicylate of mercury deep in the gluteal muscle was given in the case mentioned. The discharge of pus from the lesions was at once increased, the contents were quickly evacuated, and the furunculosis was completely healed very soon thereafter.

In eighteen other cases of well established furunculosis during the following winter and spring the patients were given the same treatment. All recovered after from one to three injections and up to May, 1917, there had been no recurrence of the infection in any one of this series of cases.

In army camps in America and in France; in the service of the American Red Cross in Siberia and Albania, and in this district of England, Southampton, this treatment of furunculosis has been satisfactory in the quick relief given the patient in the cessation of the infection.

At times the salicylate was given for ulcers of the leg, for lacerated and surgical wounds in which the healing powers seemed to be delayed, for acne vulgaris, and carbuncle, and only one absolute failure was seen, that of a case of acne vulgaris.

In October, 1923, a case of a pyogenic infection of the lymphatics was seen. This patient for four years had had repeated abscesses of the glands. In September, 1923, he was given an anesthetic and a large abscess in the axilla was opened and drained. The wounds did not heal, the sinuses continued to drain. When seen by me five weeks after the operation salicylate of mercury was given, and in twenty-four hours the sinuses were healed, and the Wassermann negative. Then for the first time it was realized that some process, far more potent than any poisonous effect of mercury, was being made active.

At once a visit was made to the municipal laboratory of Southampton. Dr. Simson the pathologist in charge was interested but sceptical. After a day or two's discussion a count was made of the writer's blood—9,000 white cells to the c.mm. were found. Salicylate of mercury was given and in twenty-four hours another count was done and 19,800 white cells were found. During the next six weeks the same control had eight other injections of mercury, with counts before and after each, and it was found that the increase was progressively less after each injection, so that after the ninth grain there was an increase of only one thousand to the c.mm. This would seem to explain the age old knowledge in the treatment of syphillis, that mercury must be given in series, with rests between each, so allowing the body to reestablish a sensitiveness to the mercury, for the stimulation of the production of more white cells.

Wishing to confirm this first count, another control was taken to the laboratory. This man was the subject of recurrent attacks of asthma, was pale and underweight. His first count was 17,000 to the c.mm. Nothing was found in his history or the examination to account for the condition of his blood, save the occasional attacks of asthma. One grain of the salicylate was given him solely for the purpose of the count on the following day. This count showed 23,500 white cells to the c.mm. Strangely enough he has never had another attack of asthma and his weight is now fourteen pounds greater than it was at that time. Other counts before and after injections of mercury were done at the Isolation Hospital, Southampton. In every case a greater or less increase was found, according to the strength and general condition of the individual.

In November these facts were reported to the Southampton Medical Society and on December 15th, published in the *Medical Press and Circular,* London.

CASE REPORT

The history of a case of furunculosis will illustrate the power of this induced increase in white cells. This patient was seen first in October, 1923. He had had phosgene gas in 1918; during his convalescence boils appeared and had continued, save during the time he was having injections of autogenous vaccine or collosal manganese. His neck, shoulders, and back showed the cicatrices of many boils. He was given one grain of the salicylate every six days for three injections. He had no more infections until June of this year. In that month he came, with a carbuncle which looked as if all the accumulated cocci of the preceding eight months had mobilized at this one region of the dorsal section of his back. The skin over the site of the infection was very thin, broken in spots and a scanty mucopurulent exudate was seen. He was given one grain of the salicylate of mercury; no incision was made in the carbuncle. There was a profuse discharge of pus within two hours, and twenty-four hours after the injection, the core and the several foci were removed by one of his family. When the lesion was seen forty-eight hours after the injection, the cavity left was granulating. The search for the focus from which this and the preceding infections had come was begun by a visit to Dr. Aldridge for an x ray of the roots of the teeth. One bicuspid and two molars were found to have septic roots. These were drawn. The patient was given another injection of the salicylate one month later. There have been no other infections, the patient has gained weight and appears to be normal, so the resistance induced by the injection of salicylate would seem to have controlled this infection for eight months.

In the paper mentioned above it was stated that an attempt would be made to see the effect of the induced increase in white cells on other infections. In November there were twelve patients with trachoma, to whom passage had been refused to the United States and Canada because of this infection. Dr. McGee, the medical officer in charge of the Atlantic Park Hotel, where they were detained, kindly furnished the opportunity for further use of the induced increase in white cells.

Injections of salicylate of mercury were begun in November. Improvement was marked during the succeeding weeks, one grain being given every six days. To the original twelve cases nineteen other cases have been added, during the following months, all the patients being from Russia or Poland. Granules gradually disappeared, bloodvessels again were to be seen, and as the weeks passed the trachomatous lesions were replaced by glistening cicatricial tissue. The mercury was given in series of about ten injections each. The usual local treatment of rolling the lids for the expression of the contents of the granules, application of copper sulphate, or perchloride of mercury was used on all cases.

Of the thirty-one cases, twenty-two patients are in the United States, Canada or South Africa, all

of which countries have strict laws against the admittance of trachoma. All these patients, therefore, have passed all examining officers here and at the ports of destination as being cured of trachoma. Dr. Arthur Zorab, of the Southampton Eye Hospital, acted with me as consultant in these cases, which were under the immediate care of Dr. McGee.

Good results have been seen also in hay fever, pleurisy, arthritis of septic origin, infectious conjunctivitis or "pinkeye," acute otitis media, tonsillitis and influenza, and lymphangitis, following typhoid fever. In not one of these infections has it been necessary to give more than four injections, usually only one.

In the late winter or early spring of this year many cases of encephalitis lethargica were reported in the north of England. A letter was sent to Dr. Stallybras, of the Ministry of Health, Liverpool, recounting somewhat of the observations of the induced increase in white cells here, and suggesting that it might be useful in Encephalitis. As a result the plan was tried by Dr. Rundle, of the City Hospital, Fazakerley, Liverpool, in thirty cases. The staff of that hospital agreed on the benefits accruing from the use of the salicylate—"All cases showed improvement. In some this improvement was striking." Sufficient promise at any rate for a much more extended use of the principle when the infection reappears next winter.

The observations of a very extensive use of this drug for eight years have convinced me that mercury cures nothing, that its value lies in the stimulation of the production of white blood cells, so bringing to bear upon the invading organisms all the purely natural forces of the body against infection.

The Treatment of Diseases of the Maxillary Sinus from the Viewpoint of a Dentist

BERNARD J. CIPES, D.D.S.
Mount Vernon, N. Y.

It is perhaps fair to state at the outset that the treatment of maxillary sinusitis falls in the majority of instances in the realm of the rhinologist. But on the other hand, the treatment has been inadequate and will continue to be so until there is a universal appreciation of the etiological relation of dental infections to maxillary sinus disease.

The time has not yet come when the frequency of antrum disease due to dental infections can accurately be determined, but our own experience shows that it occurs more often than is generally admitted. Ballenger (1) maintains that the maxillary sinus may be infected from the nose or the teeth, the cases probably being about evenly divided between these two sources of infection. Hays (2) asserts that the majority of cases of chronic disease of the antrum arise from some necrosis of the jaws or teeth. Other authorities differ in their opinions as to the relative frequency with which oral etiological factors are encountered. They agree, however, that with the advent of present day diagnostic methods and the tendency towards complete dental examination in many of these cases, this cause of antrum infection is frequently disclosed.

The following cases were selected from a large number treated during 1923 (3). They present excellent examples of oral and dental etiological factors in maxillary sinus disease.

Case I.—I. S., aged thirty-five, first seen June, 1923. Was referred from a nose and throat clinic for a dental diagnosis. He suffered from chronic maxillary sinusitis for three years. He had received treatment at the hands of two rhinologists. Intranasal treatment (irrigations) was given on three different occasions, with no permanent relief. His general physical condition was good. Wassermann was negative. There was an involvement of the left antrum and patient complained of headache and pain in that region. General mouth hygiene was good. Gingiva and soft tissue were in excellent condition. Several teeth presented well filled cavities. All the upper teeth were present. The upper left first molar was carious and nonvital. Radiograms revealed an area of rarefaction about the roots of the upper left first molar. The tooth was removed using the socalled surgical removal method. The pathological area about the roots was found to involve the antrum. A radical antrum operation was performed and the antrum thoroughly curetted. Four months later the patient had no recurrence of symptoms. The oral opening had completely closed. The striking feature about this patient is that he was treated for over two years before the cause of his trouble was discovered.

Case II.—M. E., aged thirty, was seen June, 1923. Three weeks before presenting himself at the clinic he had a superior right first molar extracted. Since that time he noticed a discharge of pus from the socket and a foul odor in his mouth. Transillumination and radiographic examination revealed the presence of pus in the right antrum. A probe into the molar socket was easily passed into the antrum. The antrum was irrigated daily with warm saline solution, through the molar socket. On the fourth day the washings were free from pus. Four weeks later the molar socket was practically healed and symptoms had entirely disappeared.

Case III.—A. S., aged thirty-nine, was seen May, 1923. Upper left second molar was extracted two months before. Socket had not healed. Patient complained of a discharge of pus from the socket and neuralgic pain. Examination of socket revealed an abundance of unhealthy granulation tissue. Radiograms showed involvement of the left antrum. The socket was curetted and found to lead into the antrum. The antrum was irrigated with warm nor-

mal saline solution daily for one week. Five weeks later all symptoms had disappeared and molar socket had healed well.

CASE IV.—H. G., aged forty-eight, was seen October, 1923. Patient was referred by his physician.

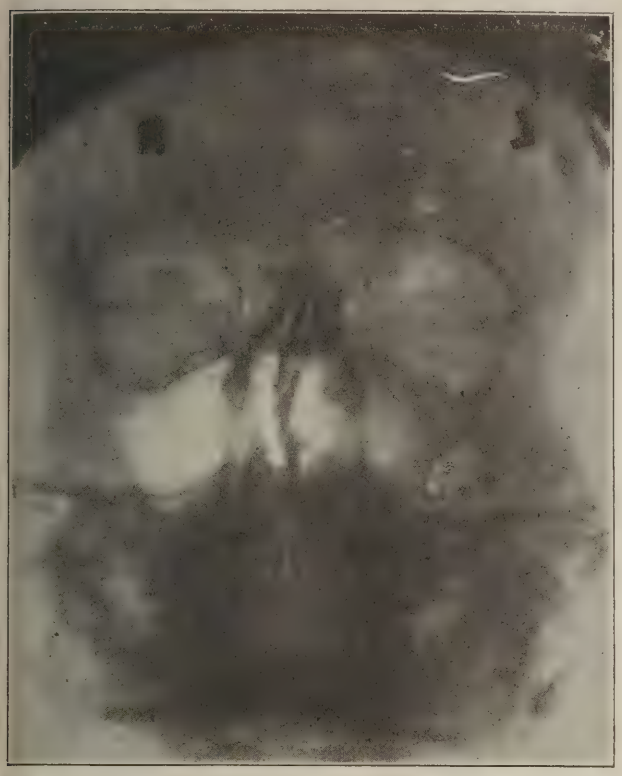

FIG. 1.—Radiogram showing area of rarefaction around the roots of upper first left molar. (Case I).

He had suffered from neuralgia for three years. His general physical condition was fair. He complained of a discharge of pus into his throat and occasionally from his nostril. The superior second and third molars were the only teeth present in the superior maxilla. Radiograms revealed a clouding of the left antrum and an area of osteoclasia about the roots of the upper left second molar. Upon the removal of the second molar, thick foul smelling pus was discharged through the socket. The antrum was curetted. Warm normal saline solution was used to irrigate the antrum every day for a week. Three months later the neuralgic pains had almost entirely disappeared and the patient felt improved in general.

ANATOMICAL CONSIDERATIONS

The antrum of Highmore or the maxillary sinus is the largest air cavity associated with the nasal chamber. The floor of the antrum is usually on a level with the floor of the nasal cavity. It may vary, however, in this respect. The size of the sinus varies in different skulls. Even on the two sides of the same skull great variations sometimes exist. The antrum is pyramidal in shape. Its base is formed by the lateral wall of the nasal cavity and its apex extends into the zygomatic process. The floor of the antrum is formed by the alveolar process. The maxillary sinus communicates with the nasal fossa through the ostium maxillare. Eminences on the floor of the antrum mark the position of roots which may directly communicate with the antrum (4). Normally, the mucous membrane lining the antrum includes a stratified ciliated columnar epithelium, a delicate basement membrane and a tunica propria which is blended with the periosteum (5).

A disease process of dental origin may elevate the mucoperiosteal lining of the antrum without entering the antrum proper and result in a para sinusitis. On the other hand, when the mucoperiosteum is penetrated and the antrum is entered the condition resulting is known as a pyosinusitis. Careful consideration of the various oral and dental conditions that may lead to involvement of the antrum is a very important factor in the proper diagnosing and treatment of maxillary sinus disease. In view of the anatomy and great variation in size and position of the sinuses, it is not surprising to find the following teeth of the superior maxillæ, involving and complicating disease of the antrum: First molar, second bicuspid, third molar, second molar, first bicuspid and cuspid, in the order named.

Without attempting a detailed classification of all the oral etiological factors in maxillary sinus disease, it will not be amiss to mention some of the numerous oral causes of antrum infection.

1. The antrum may be involved in the extraction of a tooth whose apex entered the antrum. This leaves an opening from the mouth to the antrum. The opening may heal without any untoward results. In some instances, however, it may be a portal of entry for microorganisms and contents of the oral cavity which may result in infection.

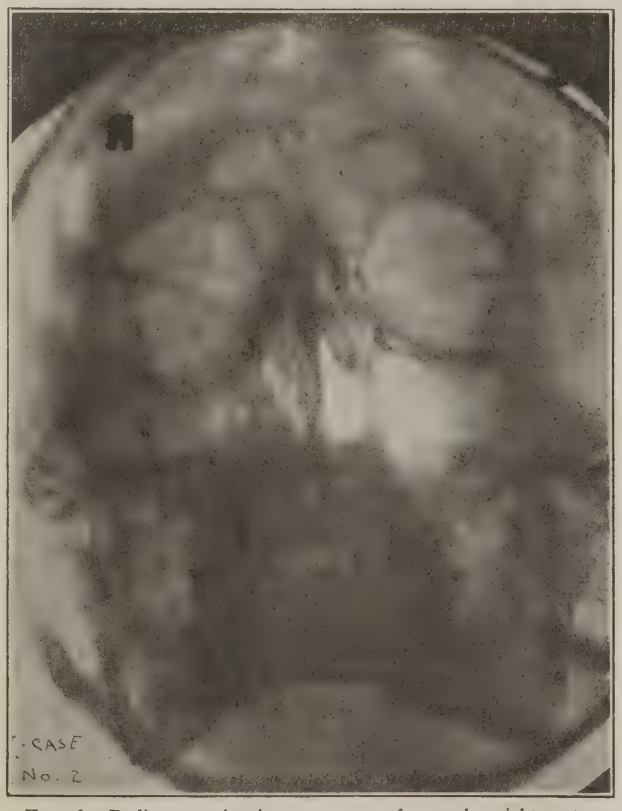

FIG. 2.—Radiogram showing presence of pus in right antrum (Case II.)

2. In performing root therapy on a tooth, the apex of which is in the antrum, it is possible to involve the antrum. Foreign bodies, such as root canal

filling materials, or parts of instruments, medicaments of a very powerful nature as well as pathogenic microorganisms, may be introduced into the antrum during this operation, particularly when carelessly performed.

3. It happens occasionally that a maxillary cuspid or third molar enters into or is situated in close proximity to the antrum. In the removal of impacted, unerupted, malposed and supernumerary teeth it may be impossible to avoid the antrum. Moreover, it is well to bear in mind the possibility of forcing such a tooth into the antrum and of pathological conditions developing about these unerupted teeth.

4. In the socalled surgical removal of teeth, particularly when retained roots are to be removed, the antrum is often involved. An inexperienced operator in the field of oral surgery may penetrate the antrum while using a surgical burr, gouge, chisel, elevator, or forceps. Involvement of the antrum, due to the removal of too much bone, in the performance of the operation known as alveolectomy, has been observed recently. This accident usually occurs in the third molar region.

5. Probably the most important etiological factor is the group of pathological processes, namely, the acute and chronic dentoalveolar abscess, cysts, necrosis and osteomyelitis. The primary origin of the most common of these pathological conditions, the dentoalveolar abscess, usually is putrefaction and fermentation in a pulp canal, following devitilization by caries or trauma. Invasion of pathogenic microorganisms into this area of lowered resistance occurs readily. Whatever the cause these areas increase in size and often penetrate the antrum. These processes often progress insidiously and are perceptible neither to the patient nor observer. Pus may be discharged into the antrum for some time, from such a focus, before it is discovered and treated. Cysts of the antrum are not uncommon. They may be of various types. The dentigerous and dental cysts are the two most common types. The dentigerous cyst develops from cystic degeneration of the wall of the tooth sac. Dental cysts may develop from diseases of the teeth and adjacent structures. These cysts may extend to and break down the wall of the antrum, and wholly or partially obliterate the antrum. Necrosis and osteomyelitis may develop from diseases of the teeth, pericementum or alveolar structure. They may result in a widespread destruction involving the antrum.

6. Another cause of antrum involvement is trauma and fractures. Teeth may be entirely or partially luxated into the antrum due to injury. Fractures of the superior maxilla are sometimes complicated by antrum involvement.

7. There is a condition known as interstitial gingivitis which sometimes leads to affection of the antrum, particularly when the inflammation is of the ulcerative type. The term interstitial gingivitis includes not only the gum borders but the interstitial tissues as well and implicates all the alveolar structures: including the pericementum, connective tissue, gums and bone (6).

8. The various neoplasms of dental and oral origin may involve the antrum. Owing to the fact that the antrum is normally a hollow organ, these growths may attain considerable size before they are detected.

9. In this class we may list special etiological factors, such as lesions of infectious diseases in the mouth. Among these diseases may be mentioned syphilis, tuberculosis and actinomycosis. They may attack the antrum via the periosteum and bone of the superior maxilla.

These considerations of the etiological relation of oral conditions to disease of the maxillary sinus prove conclusively that a careful dental diagnosis is indispensable in all cases of antrum infection. Moreover, they show that the dentist and oral surgeon must realize his great responsibility when called upon to diagnose or treat any of these conditions. Great care and a wide clinical experience are essential if one is to operate upon teeth or oral lesions which may give rise to involvement of the antrum. The operator must avoid injudicious use of instruments, particularly the curette and gouge. And while the treatment of the antrum belongs primarily to the rhinologist, a competent oral surgeon can obtain excellent results in cases of dental origin.

It is exceedingly difficult to draw a sharp line of demarcation between the field of the oral surgeons and that of the rhinologists. The oral surgeon should not attempt to treat cases of nondental origin, while the rhinologist will serve the interest of his patient best in the realization that many antrum affections of dental origin fall within the sphere of a competent oral surgeon.

SUMMARY

1. In the treatment of maxillary sinus diseases, the rhinologist often fails to consider the possibility of oral etiological factors in the case.

2. There are a variety of oral and dental causes of antrum disease that can be detected only by a well trained dentist.

3. The examination of the oral cavity by the dentist should include radiograms and transillumination.

4. Every case of antrum disease calls for a thorough mouth examination.

5. A more thorough understanding and better cooperation between the physician and the dentist will benefit the patient, alleviate suffering and even disability.

I am indebted to Dr. B. Stivelman, medical superintendent, Montefiore Sanatorium, for his kindness in correcting the proofs; and to Dr. Charles Vetter, whose instruction and cooperation have made possible this paper.

The Influence of Röntgen Rays on the Endocrine Glands*

With a Contribution to the Problem of Rejuvenation in Women

HARRY BENJAMIN, M.D.
New York

In writing the title of my paper, The Influence of X Rays on the Endocrine Glands, I almost felt tempted to add as a subtitle, "as much as we know about it."
